HAEMOLYTIC DISEASE OF THE NEWBORN:
CRITERIA OF SEVERITY

BY

P. L. MOLLISON, M.D., M.R.C.P. AND MARIE CUTBUSH, B.Sc.Melb.

(From the Medical Research Council Blood Transfusion Research Unit, Department of Obstetrics,
Postgraduate Medical School of London)

Haemolytic disease of the newborn can now be diagnosed with certainty at the moment of birth by means of the direct Coombs test. However, since this test seems to be positive in all cases of haemolytic disease, criteria are needed to assess the severity of individual cases. Such criteria are not only desirable for the purpose of deciding whether a case requires treatment but are essential for the orderly presentation of data. Of course it is possible to divide cases into the broad classes of hydrops foetalis, icterus gravis neonatorum, and congenital anaemia of the newborn, but close study of the disease reveals every possible gradation between these classes, and any division between them must be arbitrary. Because of this difficulty of grading it is impossible to tell whether different published series of affected infants include similar proportions of severe, moderate, and mild cases; and it is thus impossible to form precise conclusions on the value of different methods of therapy.

Wiener (1946) suggested that the form of anti-Rh in the mother's serum determines the clinical manifestations of haemolytic disease in her infant, but he has recently modified this opinion and now suggests that "blocking" antibodies play the dominant part and that their titre is roughly proportional to the severity of the disease (Wiener and Gordon, 1948); and Davidsohn and Stern (1948) have presented evidence that "blocking" antibodies are associated with more severe forms of the disease than are *sensitizing* agglutinins. Nevertheless, present opinion has probably been fairly summed up by Diamond (1947): "A prognosis based on antibody tests . . . must be offered with reservations."

Doubtless the search for measurable criteria of severity has been discouraged by the general belief that, in some cases at least, the disease "comes on," or at least increases in severity, after birth. If this were true it would be extremely difficult to make comparisons between cases in view of the variable changes in haemoglobin and bilirubin values that occur after birth as normal phenomena. However, close study of the disease suggests that in fact the haemolytic process is maximal at birth.

This paper presents evidence that the haemoglobin value of the cord blood, determined by an accurate method, is a satisfactory criterion of severity and that knowledge of this value enables one, within limits, to give a reliable prognosis.

Clinical Material

Normal Infants.—In the course of this work cord blood was collected from 52 healthy full-term infants; in addition, venous samples were taken from many of these infants some hours after birth. In 12 of these latter cases the cord was deliberately clamped immediately after the birth of the

infant, and in a further 12 cases the cord was left for a full five minutes after birth. Finally, capillary blood of blood were taken on the first day of life from 33 healthy infants, including 22 from whom venous blood were taken simultaneously.

Infants with Haemolytic Disease.—Seventy-four infants were studied, although not all of the tests described below were made on every case. All these infants were born to D-negative mothers whose sera contained (with or without traces of anti-C or anti-E). In most cases the presence of antibody was first detected by routine during pregnancy. Sixty-nine of the infants were alive, and all were demonstrated to be positive to the Coombs test; in a few cases in which the mother had been tested during pregnancy, and in which the infant was seen by us only after it had developed signs suggestive of haemolytic disease, the diagnosis was first established by the finding of a positive direct Coombs reaction in the blood of five stillborn infants was not tested.

TABLE I

No of Cases	Hb first Determined	Treatment		
		Nil	Simple Transfusion	Exchange Transfusion
50	Cord	10 (3 moribund)	1	19
	Few hours after birth	0	0	20
	2-5 days	2	13	2
	30 days	1	0	0
	Untested (5 stillborn, 1 moribund)	6	0	0
74		19	14	41

Fifty infants were seen and tested on the day of birth (see Table I), and the findings in this group form the basis from which our main conclusions have been drawn. Ten of these infants were not treated—in three cases because they were moribund and in seven because they were considered to be too mildly affected; all of these seven recovered uneventfully. In one further mild case a simple transfusion of Rh-negative blood had to be given on the first day of life because the infant bled from its cord. The remaining 39 cases in this group were treated by exchange transfusion. Thus treatment was essentially uniform, and it seems justifiable to draw conclusions about the severity of the individual cases from the outcome.

In 18 further cases the infant was not tested until after the first day of life. The findings in this group have been used to supplement conclusions reached from the first 50 cases.

Of the 74 cases, 63 formed the material for a previous communication on treatment (Mollison and Cutbush, 1948).

As is well known, petit mal attacks frequently coexist with major seizures: about two-thirds of children beginning with petit mal develop grand mal. If, however, such children remain free of major seizures the attacks may cease entirely after a few years, with no impairment of mentality even after many thousands of attacks. This pure form was described by Adie (1924) and others as "pyknolepsy." Lennox (1945a) prefers the name "pykno-epilepsy" to emphasize that they are not something different from epilepsies. Since they are now recognized as identical with petit mal there is no need to retain either of these additional names.

The nature of the petit mal is especially obscure. An epileptic discharge in an area of complex activity such as a speech area causes, as already noted, a loss of function—not the production of words but speechlessness. Pure loss of consciousness seems to indicate an inhibitory discharge in the highest level of integration in the nervous system. The electrical changes both during and between petit mal seizures are the most constant and characteristic of all types of epileptic discharge, and they arise symmetrically and synchronously over a wide area of the cortex but chiefly in the frontal lobes. Penfield (Penfield and Erickson, 1941) argues, however, that there can be no final re-representation of sensorimotor functions in the frontal lobes, since the removal of large parts of these does not abolish conscious processes in man, and he suggests that the level of final integration lies in the region of the hypothalamus.

Release Phenomena in Epilepsy

After a major epileptic attack the patient may for a time exhibit co-ordinated activity, which is, however, obviously uncontrolled, or unconscious in the sense that the patient has no awareness of what he is doing. Similarly, certain attacks occur which are characterized solely by abnormal behaviour except that at the onset there may be clonic movements of the jaws, grimacing or muttering, occasionally a writhing or turning movement of the trunk. Such attacks, which are not uncommon, have in the past usually been explained as post-epileptic automatism, the assumption being that they were sequels of a brief petit mal seizure. It is doubtful, however, whether there is any unconsciousness, though there is an alteration of consciousness indicated by complete amnesia for the whole episode. The term "psychomotor attack" or "psychic equivalent" is now usually used for them: their clinical distinction from other types of seizures is supported by distinctive electroencephalographic tracings.

These attacks of elaborate but purposeless activity, whether they constitute the whole attack or follow a recognizable epileptic incident, must be due to release of lower mechanisms from conscious control. The highest centres, whatever may be their neural site, are either inactivated directly by an epileptic discharge or exhausted by such a discharge, as a limb may be paralysed after a local motor seizure.

The type of activity shown in automatism is of great variety, but tends to repeat itself in successive attacks in the same patient. Usually harmless, it may include violence or indecent exposure and thereby assume serious social or medico-legal significance.

Epileptic Myoclonus

Many patients subject to major epilepsy exhibit between attacks sudden sharp myoclonic jerks, usually limited to movements of the upper limbs, and commonly described by patients or relatives as "he jumps." They occur

Rarely, an attack may jerk the patient suddenly to one side and bring him to the ground. Of considerable value in diagnosis, and occasionally the sole manifestation of an epileptic tendency, they are difficult to explain, for they are usually bilateral and associated with bilateral cortical discharges in the electro-encephalogram and yet are unaccompanied by any loss of consciousness.

Status Epilepticus

In this condition the patient has attacks of major epilepsy recurring for hours or days without recovery of consciousness. Isolated attacks, however frequent, with recovery between attacks, are not status epilepticus.

ESSENTIAL MECHANISMS

Irritation (positive discharge), inhibition (negative discharge), and release—these seem to be the essential mechanisms in epilepsy: they are seen most clearly in local epilepsy, but are also detectable in generalized attacks. Conceived and elaborated by the philosophical mind of Hughlings Jackson, they are not invalidated by later researches, and remain sound hypotheses which help in the interpretation of clinical phenomena.

Diagnosis of Epilepsy

The separation of epilepsy from other paroxysmal disorders is a common clinical problem. Gowers (1907) included within "the borderland of epilepsy" fainting or syncope, vasovagal attacks, vertigo, migraine, and certain disturbances of sleep, including narcolepsy; he was, however, careful to say that these troubles seem to be "near epilepsy, but not of it." Twenty years ago, in his Lumsden Lectures, Collier (1928) went further, feeling that these disorders, as well as tetany, were closely related to epilepsy and that some metabolic dyscrasia might underlie them all. However, such biochemical changes as have been found in epilepsy cannot be regarded as primary or causative.

Purdon Martin (1945) has expanded Jackson's theory of the discharging lesion, applying it to a wide variety of paroxysmal disorders as well as to some conditions of continuing irritation such as the thalamic syndrome. He does not suggest that any of these is epileptic. Gibbs and Lennox (1938), however, suggest that a disturbance which is essentially epileptic—involving abnormal rhythmic activity—may start in any portion of the nervous system. In clinical epilepsy this is in the cortex: but this conception extends to chorea, Parkinsonism, neuralgia, etc.

There seems a danger here of theory outstripping experience. There may well be many types of discharging lesion, but it does not follow that all these phenomena are epileptic. Williams (1944) sees a similar danger in the presence of electro-encephalographic disturbances of an epileptic kind in many conditions not usually considered epileptic—for example, faints and toxic convulsions. If all these electrical changes are to be regarded as epileptic "the limits of epilepsy will become so wide as to make the term meaningless."

In the uncertain state of knowledge of these various disturbances of nervous function, classification should rest on clinical distinction. Viewed in this light the resemblances between migraine, faints, etc., and epilepsy become less impressive than the differences between them. For a clinician a diagnosis of epilepsy carries certain implications: it means that there may be serious intracranial disease, and involves the possibility of progressive mental deterioration and always of certain social implications which do not arise in other paroxysmal conditions.

in doubtful cases, for in many the answer is obvious—between epilepsy and the fainting or syncope attack. According to Lewis (1933), in a faint there are two distinct but simultaneous processes—namely, a slowing of the heart by increased vagal tone, and a fall of blood pressure by vascular relaxation, chiefly in the splanchnic area. These reactions are produced reflexly through a central nervous mechanism. The term vasovagal attack is therefore used by Lewis as an alternative to fainting or syncope, and such attacks are not epileptic, for they are not primarily neurogenic and they carry none of the implications of epilepsy. Between fainting and petit mal as formerly defined a careful history should distinguish, but between fainting and the akinetic type of epileptic attack, with loss of consciousness and falling but without convulsion, the resemblance is close. On the other hand, in a faint there may be clonic movements: they are usually slight in spontaneous faints, but are well known in cardiac syncope. Experience with blood donors has shown that they are sometimes marked (M.R.C. Report, 1944). In a recent paper dealing with attacks of unconsciousness in five hundred members of the Royal Air Force, Rook (1947) observes that "the occurrence of twitching or even major convulsions in association with loss of consciousness does not justify a diagnosis of epilepsy on these grounds alone."

The one feature which is almost diagnostic is that a faint is a reactive phenomenon, a fit rarely so. The stimulus in the great majority of cases is emotional, though fatigue, recent blood loss, or other factors impairing the general health may facilitate the reaction. Difficulty arises because persons predisposed to fainting the emotional stimulus may be a very slight one. Epileptic attacks are only rarely due to a direct emotional or reflex stimulus, but, as already noted, such a sequence does occur occasionally. Fox (1941) observes that as a generalization the statement that excitement causes fits is false: boredom, anxiety, and worry do, however, predispose in certain cases. He reported that when the patients under his care were subjected to frequent air raids there was no increase whatever in the frequency of their attacks. Shafar (1941) found this equally true of out-patients attending a London hospital throughout the war years.

The Syndrome of Gowers

Unfortunately the name "vasovagal" was given by Gowers (1907) to a syndrome of a different order which is certainly not a simple syncope, and whose relationship to epilepsy is also unconvincing. The picture in these attacks is not a uniform one, and this probably accounts for varied reports about their frequency. The features of a severe attack include extreme pallor, coldness, difficulty in breathing, pain of anginal distribution, and the *angor animi* or sense of impending death which Ryle (1939) stresses as the foremost feature. The attacks may last half an hour or more. In nearly all the patients there is a strong background of anxiety. Personally I have seen only a few cases in which the pattern of the attack corresponded closely to this severe type, but many in which a state of anxiety was associated with milder manifestations of the same order. Though there is no evidence of cortical disturbance and no unconsciousness or amnesia, they have been held to be epileptic variants in which autonomic disturbances dominate the picture instead of constituting only subsidiary features as in major epileptic attacks (Wilson, 1928). An occasional patient has also been epileptic, and a family history of epilepsy, mixed with depression or psychosis is quite frequent: in 2 parts out of 3 does not place these attacks as thus estimated to be epileptic. They are clinically 16.2 g. (the measurement of the

tent evidence of either vasomotor change or vagal inhibition. The term vasovagal attack, if used at all, should therefore be employed in Lewis's sense as an alternative to syncope or fainting due to transient cerebral anaemia.

Laryngeal "Epilepsy" and Breath-holding Attacks

Also more closely allied to syncope than to epilepsy are attacks due to respiratory obstruction. One type is the so-called laryngeal epilepsy first described by Charcot as laryngeal vertigo. The attack follows coughing, and the subjects are usually of plethoric type with chronic laryngitis or bronchitis. In spite of an absence of previous or family history of epilepsy Whitty (1943) thinks that these attacks are primarily neurogenic—that is, caused by venous congestion in a predisposed person. Rook (1946) saw four cases in the Royal Air Force due to coughing or choking, in three electro-encephalograms were done and were normal. A predisposition must be admitted, since chronic coughs are so common and these attacks infrequent, but, as in predisposition to fainting, this is not a convincing argument for an epileptic basis.

Not so rare are the breath-holding spells of young children: in the North of England mothers call them "the kinks." Bridge and others (1943) reported 83 cases from the Johns Hopkins Hospital, of whom 60% became unconscious and 40% had convulsions. Two of these children became epileptic and two probably did. But this is not epilepsy. It seems to me that great caution is needed in diagnosis, but if this is correct the treatment is of the psychological causes of the habit.

Narcolepsy and Cataplexy

Narcolepsy is theoretically nearer to epilepsy, as it is certainly a neurogenic disorder. Again some have sought to include this syndrome within the all-embracing concept of epilepsy, but we must separate it decisively on clinical grounds. Electro-encephalographic reports are contradictory, some showing an epileptic type of change (Cohn and Cruvant, 1944) and some only sleep changes. Narcolepsy means attacks of irresistible sleep or of a condition which resembles sleep (Nathans, 1938). They are preceded by an intense feeling of fatigue, and can often be resisted for a time but seldom prevented: they last usually a few minutes, but it may be only a few seconds, and, exceptionally, if the patient is undisturbed he may continue to sleep. He is usually awakened easily and is alert at once. Frequency of attacks varies, but is usually fairly constant in each patient: there may be two or three daily or one every few minutes.

Cataplexy means attacks of loss of power and of tone induced by emotion of any kind, but especially hearty laughter. There is no loss of consciousness, but the patient sinks to the ground, unable to move or speak for perhaps half a minute. During the attack, as I have verified on several occasions, in striking contrast to inhibitory epilepsy, the tendon jerks are abolished and the plantar reflexes normal; the jerks return instantly when the attack is over. If a cataplectic attack is resisted it may pass into sleep.

The combination of narcolepsy and cataplexy which occurs in the majority of cases is unmistakable. If either type of attack occurs alone, confusion with epilepsy is possible. No case exhibiting the complete syndrome of sleep attacks plus cataplexy has been reported as developing into epilepsy.

Other Types of Immobility

In cataplexy inhibition of postural tone is an essential feature. Certain other states of immobility occur in which tone is unaffected and posture maintained. This is cataplexy, which in association with "waxy flexibility" is one of the motor phenomena of schizoid

Here the immobility is present. Rudolph (1946a, 1946b, 1947) has drawn a condition which seems best explained as *trance*, and which is known to nurses as "night myiasis." In an attack the individual becomes suddenly in either a standing or a sitting position, unresponsive but fully conscious and able to see and hear. The attack may last for a few seconds or a few minutes. A similar fixity may result from intense fear; but anxiety is not concerned in the attacks under consideration as they are apparently induced by fatigue. It has been found that such attacks occur in others besides epileptics, especially in people whose work keeps them standing for long periods of time, of no serious significance, and not a condition which medical advice is sought, it is occasionally met with in the case of a naval officer who had to be on the ridge of a minesweeper because he was unable to prevent an imminent collision. Such a state will be mistaken for petit mal, but there is absolute loss of consciousness.

"Sleep paralysis" is a condition occurring when a person awakes from sleep less frequently, just before he falls asleep. It is a condition in which subjects and occasionally in normal people in the case of post-epileptic paralysis is sometimes induced as cataplectic attacks induced by a terrifying experience which awakens the subject but leaves him unable to perform several minutes.

Paroxysms

Labyrinthine vertigo is of much interest to physicians, as it comes to them in their instance more often than to otologists. The attack there is a powerful sensation of movement, surrounding objects, as frequently of the patient, usually rotatory, to right or left, sometimes vertigo, occurrence of vomiting, staggering, or falling is a feature of severity of the attack. Difficulty in diagnosis arises in various ways. First, some attacks are extremely sudden and brief: the patient is flung to the ground and wakes, but picks himself up at once without secondarily there may be deafness or tinnitus: these appear to be in labyrinthine disease, or they may be because the lesion is in the ear but in the central nervous system, the labyrinth in disseminated sclerosis after brainstem lesions. Secondly, with the vertigo there is a transient loss of consciousness. I believe this is very infrequent, and the absence of any unconsciousness, any loss of convulsive movements distinguishes it from any type of epileptic attack.

Migraine

Clinically a certain similarity between migraine and epilepsy is due to the occurrence of focal cortical disturbances in both. While typically symptoms in migraine precursors of headache, occasionally occur independently of headache, and tend to do so in later life. However, they differ from epilepsy markedly in several respects. The scotomata, and fortification spectra of migraine are due to focal or temporal phenomena which occur in the occipital or in the visual aura area. Attacks, both of the character and in their duration, pre-headache symptoms of migraine are of a local sensory character, their much slower speed, lasting about 10 minutes, their predilection for the face, lips, and fingers, with infrequent involvement of the leg, and as Gowers (1907) pointed out, in that they are generally, as in both

panies a migraine attack is perhaps more difficult to distinguish from other cortical lesions. Those who are impressed by a close association between migraine and epilepsy seem to me to have overstressed the clinical resemblance between the two.

Aetiologically the relationship of migraine and epilepsy is puzzling. There is impressive evidence (Schumacher and Wolff, 1941; O'Sullivan, 1936) that the cortical phenomena of migraine are due to constriction of cerebral arteries, and that the subsequent headache results from dilatation and excessive pulsation, chiefly of branches of the external carotid. The occasional persistent hemianopia which follows a migraine attack (Adie, 1930) seems likely to be due to prolonged constriction. Vascular changes of this nature have no counterpart in epilepsy, and the pathogenesis of the two kinds of attack seems to be entirely different.

On the other hand there is undoubtedly a genetic relationship between the two disorders. The strongly hereditary character of migraine is not in doubt, but there is also a high incidence of migraine in the families of epileptics. Ely (1930) reported that of 171 persons suffering from epilepsy only 14% gave a family history of epilepsy but 60% gave a history of migraine in a former generation. There is, however, no special incidence of epilepsy in the families of sufferers from migraine. This seems to suggest that migraine is possibly the morbid ancestor of both migraine and epilepsy. Electro-encephalographic studies of migraine subjects have yielded varying results (Lennox, 1946; Dow and Whitty, 1947).

It is doubtful whether any practical deductions can be drawn from these observations connecting epilepsy and migraine. Migraine, though it causes an immense volume of suffering, is a much less serious disease than epilepsy. Lennox says that the two are emphatically not brothers but only some order of cousins. Nevertheless, in his admirable book *Science and Seizures* (Lennox, 1946) he calls migraine "headache seizures" and rather stresses a relationship to epilepsy because he feels this is encouraging for epileptics. No doubt this is true, but it is surely no less discouraging for the much more numerous migraine subjects to be given the idea that their headache attacks are akin to epilepsy. I do not think it is justifiable to speak of a "migraine-epilepsy syndrome."

The Practical Problem

In the present state of knowledge, even if electro-encephalographic records are available, the diagnosis of epilepsy is a clinical decision based on a summary of the evidence. It is therefore helpful to follow a simple plan, beginning by talking with the patient alone, and thereafter interviewing relatives or other observers separately. Children of school age can often give the necessary information as well as adults.

What can the patient tell us about an epileptic fit? Sometimes absolutely nothing, not even that he has fits. For example, the patient may be unaware that he is subject to convulsions in sleep or that he has petit mal during the daytime. In most cases he knows he has had an attack, seizure of some sort, or a series of attacks. He should be asked, "What is the first thing you notice when an attack occurs?" A minority of patients have no warning and become instantly unconscious. But in most cases the question is a vital one, for it brings out information about the aura or first stage of the major fit, and thus precise localizing significance; while in some cases the patient can describe the whole attack. Secondly, the patient can tell us

ey
nd it
from
is are
a non
ent

Principles of

attacks; prominent among these are headache and a desire to sleep, signs of injury, tongue-biting, incontinence of urine, vomiting, and soreness of muscles.

Then we can hear from the patient of the time of attacks, in particular their relation to sleep and to menstruation. As to sleep, the attacks may (1) occur during sleep, which is virtually diagnostic—of these the patient usually knows by his condition on waking; (2) if diurnal, show a marked predilection for the early morning hours; (3) occasionally occur just as the patient falls asleep. Further, an account of morning myoclonus is common and helpful.

Finally, though the patient cannot tell us of his actions in a state of automatism, he is often aware of this condition through circumstantial evidence, such as finding he has fallen into some strange place. The second part of the history from relatives, may be decisive, but is often inconclusive.

Aids to Diagnosis

The Electro-encephalogram.—Only if attacks are induced artificially, or if the patient is having frequent attacks under observation, is it possible to observe the distinctive seizure patterns. Confirmation of a clinical diagnosis, or help in a doubtful case, therefore depends on any variations from the normal which may be found in the resting record. Certain paroxysmal discharges seen in this record are virtually diagnostic of epilepsy: clearly defined "larval" attacks—i.e., electro-encephalographic but not clinical attacks—were never found by Williams (1944) in non-epileptic subjects, and the only case in 8,000 in which a wave-and-spike outburst (the type associated chiefly with petit mal) was seen in a non-epileptic was the identical twin.

The Harvard workers found this type of attack in 1 in 500 of non-epileptic subjects but in 100% of those with a clinical diagnosis of petit mal. These workers, Gibbs, and Lennox, (1943) conclude that the electro-encephalogram is of great value in diagnosis, and in 42% it is of little or no value. The results depend on the frequency of examinations. They are of little value in the diagnosis of petit mal, in which class of cases clinical diagnosis is most often in doubt. It must also be recognized that not infrequently successive records in the same patient are inconsistent—a fact which has disturbed a number of clinicians (Holmes, 1946; Rook, 1947). The interpretation of records is a specialized and skilled procedure, and the results must be evaluated only in conjunction with the clinical picture.

Induction of Fits.—Two methods may be used to induce fits for the purpose of diagnosis. The first is the production of alkalosis by overbreathing, the second to cause a positive water balance by forced ingestion of water and the administration of pitressin (Blyth, 1943). A couple of minutes' overbreathing may confirm a diagnosis of petit mal or bring out paroxysmal discharges in the electro-encephalogram. Otherwise these tests are formidable and have little place in ordinary practice.

The Clinical Decision.—Doubts and mistakes are inevitable. After the most painstaking analysis of the case, the final practice, which is free from the complications encountered in the Services, the bias of the hospital case should, in my view, be towards the diagnosis of epilepsy. If there is a history of recurrent attacks, suggestive of epilepsy, though certainty is lacking, the diagnosis is more likely to be epilepsy.

Final judgment may be reserved, but a trial of treatment should be instituted.

ANTIHEMIPLEGIC DRUG TREATMENT OF ACUTE NEPHRITIS

BY

JOHN CRAIG, M.B., Ch.B., F.R.C.P.Ed.

AND

J. D. CHALMERS, M.B., Ch.B.

Supernumary Housephysician, Royal Aberdeen Hospital for Sick Children

This paper is a preliminary report on the use of "anthisan" in the treatment of acute nephritis in children. The number of cases so far treated is small, but the results have been so striking that we feel it is advisable to publish them at this stage in order to stimulate further work on the subject.

No specific treatment has yet been found which will abort acute nephritis or even appreciably modify its course. Treatment up till now has been directed towards providing rest both for the patient and, so far as this can be achieved by dietary restriction, for his kidneys, in the hope that these organs have not already been irreparably damaged and will eventually recover spontaneously. If the response we have observed to treatment with anthisan can be confirmed over larger series of cases a very material advance will have been made in the treatment of acute nephritis. In a centre such as this will be some years before we see enough cases for the proper evaluation of the treatment with adequate control. Therefore it is advisable that this work should also be undertaken at other and larger centres.

The well-known tendency for acute nephritis to occur at an interval of a week or two after an acute bacterial infection suggests that the nephritis may be in the nature of an allergic response to bacterial toxins. The relationship which seems to exist between acute nephritis and some cases of anaphylactoid purpura lends further support to this theory. It would therefore appear reasonable to test the effect of an antihistamine drug in this condition. So far as we are aware the only published work on this subject is that of Rees (1946), who has claimed good results from treatment with "antistin" both in a few cases of experimentally induced nephritis in rabbits and in a small series of cases of acute nephritis in human beings. As might be expected, he found that antistin had no effect on chronic nephritis where the kidneys are already irreparably damaged.

We have used anthisan in the treatment of eight successive cases of acute nephritis admitted to the Royal Aberdeen Hospital for Sick Children. The course of these cases has been parallel with that of the nine consecutive cases of this condition admitted immediately preceding the institution of treatment. Two cases of nephritis which were nephrotic from the outset have not been included, but, of the seven, all fresh cases of nephritis admitted to hospital between October, 1946, and October, 1948, included in either the anthisan or the control group.

The groups differ in one important respect—i.e., the cases were not admitted during the same period of time—arises is of course possible that the later cases were suffering from a relatively benign form of nephritis. The two groups are, however, closely comparable as regards the duration

oedema, hypertension, blood urea, and urinary output. The average age of the control group was 9 years and of the anthisan group 6 years.

Four cases in the control group and two in the anthisan group showed signs of active infection in the throat or ears on admission; the same number of cases in each group showed evidence of recurrent or persistent throat infection during the course of treatment. Whether or not these persistent infections had any effect on the course of the disease it is difficult to say. All patients in both groups who showed signs of active infection were given courses of penicillin or sulphonamide, but this did not seem to influence materially the course of the nephritis. Hypertensive convulsions, which occurred in one control and two anthisan cases, were treated on the usually accepted lines by lumbar puncture, hypertonic magnesium sulphate enemata, and sedatives. No other treatment was employed in either group apart from complete rest in bed until abnormal constituents had remained absent from the urine for several weeks and restriction of protein intake as long as azotaemia persisted.

For the purposes of comparison the two groups have been subdivided into "mild" and "moderate or severe" cases. Cases were classified as "mild" if there was no hypertension or oedema other than slight puffiness around the eyes and if azotaemia was absent or minimal. On this basis three cases in the control group and two cases in the anthisan group were mild, leaving six cases in each group which were moderate or severe.

Brief summaries of the important clinical and laboratory findings and of the course of all cases in both groups are given. The figure for "duration" shown at the end of each case history signifies the duration of activity of the nephritic process from the first day of treatment until the last abnormal signs had disappeared. Albuminuria or microscopical haematuria were the most persistent abnormal signs in all cases except No. 16, in which the blood urea remained raised after the urine had returned to normal.

Case Histories

Control Group: Mild Cases

Case 1.—A boy aged 11 was admitted on Feb. 28, 1948, with a six-day history of headache, giddiness, and haematuria. He had had a similar but milder attack in February, 1946. Since then, however, he had been very well, and no albumin had been found in his urine. Examination showed no oedema apart from slight puffiness around his eyes. The throat was healthy. B.P. 110/65. No other abnormality was detected. Urine: smoky, albumin ++, output normal. Blood urea 32 mg. per 100 ml. Sixteen days later his urine was free from albumin, and no red blood cells were seen on microscopical examination. Only once since then has his urine contained any abnormal constituents—namely, a few granular casts. He was discharged on April 3, and was very well when seen at the follow-up clinic two months later. *Duration:* 16 days.

Case 2.—A girl aged 10 was admitted on Feb. 6, 1948, with a history of having developed a sore throat ten days previously. Seven days later she had persistent headache, and on the day before admission her B.P. was 140/90 and her urine contained albumin ++ and scanty red blood cells and pus cells. Examination showed no oedema; the throat was healthy; there were signs of a congenital cardiac defect—probably a patent ductus arteriosus. B.P. 120/80. Blood urea 29 mg. per 100 ml. Urine: no albumin, scanty pus cells, culture sterile. Next day her urine again contained albumin, and this persisted for seven days. At no time during her stay in hospital were casts or red blood cells noted. She was discharged on Feb. 27. *Duration:* 8 days.

Case 3.—A girl aged 8 was admitted on June 19, 1947, with a history of haematuria for two days. There was no history of a throat infection, but she had been vaguely unwell for a

week before admission. Examination showed no oedema; tonsils were mildly inflamed; physical examination otherwise negative. B.P. 115/85. Blood urea 58 mg. per 100 ml. Urine: macroscopic blood, albumin ++, occasional granular casts. Her urine became free from albumin 26 days after admission, but a few red blood cells were present microscopically until the 39th day. Tonsillectomy was performed on Aug. 8 under cover of a course of penicillin, and she was discharged on Aug. 14. *Duration:* 39 days.

Anthisan Group: Mild Cases

Case 4.—A girl aged 5 was admitted on June 13, 1948, with a history of haematuria and puffiness of her eyelids for two days. She had had an attack of otitis media two months previously, and this had been followed by haematuria, but her symptoms had cleared in ten days, and she had been back at school for two weeks. Examination showed slight puffiness below the eyes. Tonsils were moderately enlarged but not inflamed. No other abnormality was detected. B.P. 132/70. Blood urea 50 mg. per 100 ml. Urine: macroscopic blood, albumin ++.

Anthisan, 0.1 g. t.i.d., was given from June 13 to June 21 inclusive. By the latter date her symptoms had completely subsided and her urine was free from albumin and red blood cells. She was discharged on June 29 to rest in bed at home for one month. She returned to the follow-up clinic on Aug. 2, having just recovered from an attack of mumps. Her urine showed a trace of albumin, but this had disappeared by her next visit to the clinic on Aug. 30, and she has had no albuminuria since. *Duration:* 8 days.

Case 5.—A boy aged 2 was admitted on Aug. 30, 1948, with a history of listlessness, pallor, and puffiness of the eyelids for two days. There was no history of an upper respiratory infection or of haematuria. On examination he was a pale, listless child with puffy eyelids but no oedema elsewhere. Apart from a soft apical systolic murmur and some enlargement of the tonsils, no other abnormality was detected. B.P. 106/76. Blood urea 20 mg. per 100 ml. Urine: albumin +, scanty red blood cells. Haemoglobin 54%.

Anthisan, 0.1 g. t.i.d., was given from Aug. 30 to Sept. 3 inclusive, and within four days his urine was free from albumin and red blood cells. On Sept. 4 albumin was again present in his urine, but thereafter no abnormality was detected. He was discharged on Sept. 15, and has since been seen twice at the follow-up clinic, his urine being normal on both occasions. This attack of nephritis was accompanied by a fairly severe microcytic hypochromic anaemia, which responded to iron therapy. *Duration:* 6 days.

Control Group: Moderate or Severe Cases

Case 6.—A girl aged 4 was admitted on June 2, 1948. Two weeks before admission she developed a respiratory infection which responded to treatment with sulphathiazole; her right ear then became painful and started to discharge. Two days before admission her urine became dark brown in colour. Examination showed no oedema apart from some puffiness around her eyes. Her throat was healthy, but her right tympanic membrane showed a loss of lustre. An x-ray film of her right mastoid showed a loss of translucency, suggesting mastoiditis. No other abnormality was found on physical examination. B.P. 125/80. Blood urea 66 mg. per 100 ml. Urine: albumin ++, no cellular deposit, output 7 (197 ml.) in first 24 hours. On June 7 gross haematuria present and there was a purulent discharge from the ear. The discharge from her ear gradually dried up, urinary output increased, and her haematuria disappeared. She was discharged on June 22, with a trace of albumin present in the urine. At the follow-up clinic, 10 days later the albuminuria had disappeared. *Duration:* over 20 days.

Case 7.—A girl aged 11 was admitted 10 weeks before admission she developed a generalized scarlatiniform rash, and two weeks before admission she became very puffy and she passed a small quantity of urine. On examination there was some

Her throat was healthy. A few rales were present at her left lung base. No other abnormality was detected. B.P. 176/80. Blood urea 51 mg. per 100 ml. Urine : albumin + + +, macroscopic blood. On Dec. 21 the blood urea was 38 mg. per 100 ml., B.P. 110/65; albuminuria was still marked, but no red blood cells were present. The albumin persisted until Feb. 26, 1948, when for the first time the urine showed no abnormality. She was discharged on March 4. *Duration* : 80 days.

Case 8.—A girl aged 4 was admitted on March 20, 1947, with a history of swelling of her face and abdomen and of passing dark-coloured urine for three days. On examination oedema of the face and limbs was present and the throat was inflamed. Physical examination was otherwise negative. B.P. 102/65. Blood urea 156 mg. per 100 ml. Urine : albumin + + +, macroscopic blood, output 8 oz. (227 ml.) in first 24 hours. By April 1 the oedema had practically disappeared; the blood urea was 82 mg. per 100 ml. and frank haematuria had ceased. Her blood urea on April 27 was 23 mg. per 100 ml. An acute tonsillitis on May 3 caused an increase in the haematuria and albuminuria. The red blood cells gradually diminished, and on May 19 the urine was free from albumin. A few red blood cells, average 2 per high-power field, persisted till the date of her discharge on July 2. These were still present at her first visit to the follow-up clinic on July 24, but had disappeared by Sept. 4. Her urine has been normal on several occasions since that date. *Duration* : over 126 days.

Case 9.—A girl aged 10 was admitted on Oct. 2, 1946. Three weeks before admission she developed swelling of the eyelids and face. A week later haematuria was first noticed; this gradually became more marked, being accompanied by oliguria. On examination no oedema was present and her throat was healthy. B.P. 155/95. No other abnormality was detected. Blood urea 52 mg. per 100 ml. Urine : albumin + + +, macroscopic blood, numerous granular casts, output 15 oz. (425 ml.) in first 24 hours. Blood urea on Oct. 19 was 28 mg. per 100 ml. The albuminuria and haematuria persisted, and the blood pressure was 140/90 on Dec. 15. On March 14, 1947, for the first time red blood cells were not seen on microscopical examination of the urine, but the albuminuria persisted. B.P. 120/70. A trace of albumin was still present in the urine when she was discharged on June 22, and again on her return to the follow-up clinic on July 16. *Duration* : over 287 days.

Case 10.—A boy aged 9 was admitted on Nov. 16, 1946. Three weeks before admission he developed a sore throat, followed a week later by a purulent discharge from his left ear. Five days before admission swelling of his eyelids was noted, and three days later there was haematuria and oliguria. On examination oedema of his face and ankles was present, tonsils infected, left suppurative otitis media. No other abnormality was detected. B.P. 140/100. Blood urea 221 mg. per 100 ml. Urine : albumin + + +, macroscopic blood, numerous granular casts, output 14 oz. (397 ml.) in first 24 hours. On Dec. 4 he developed chicken-pox and was transferred to an isolation hospital. At this time his blood urea was 50 mg. per 100 ml. and his B.P. 126/74. Frank haematuria persisted and was present on his readmission to this hospital on Dec. 27. A flare-up of his chronic tonsillar sepsis caused a further increase in the haematuria, and on Feb. 3, 1947, tonsillectomy was performed under cover of a course of penicillin. Gradual improvement took place in spite of an attack of measles starting on March 5. Red blood cells were last seen in the urine on April 28, but traces of albumin persisted until May 25. He was discharged on June 7, and until his last visit to the follow-up clinic on Dec. 24, 1947, his urine remained normal. *Duration* : 190 days.

Case 11.—A girl aged 11 was admitted on Dec. 31, 1946, having developed a sore throat three weeks previously. Four days before admission her face became swollen, and two days later her urine became dark brown in colour and she had convulsions. There were four further convulsions on admission. On examination she was drowsy and had generalized oedema; the throat was healthy. B.P. 170/120. Blood urea 100 mg. per 100 ml. Urine : albumin + + +, macroscopic blood, numerous granular casts, output 14 oz. (397 ml.) in first 24 hours. On Dec. 4 he developed chicken-pox and was transferred to an isolation hospital. At this time his blood urea was 50 mg. per 100 ml. and his B.P. 126/74. Frank haematuria persisted and was present on his readmission to this hospital on Dec. 27. A flare-up of his chronic tonsillar sepsis caused a further increase in the haematuria, and on Feb. 3, 1947, tonsillectomy was performed under cover of a course of penicillin. Gradual improvement took place in spite of an attack of measles starting on March 5. Red blood cells were last seen in the urine on April 28, but traces of albumin persisted until May 25. He was discharged on June 7, and until his last visit to the follow-up clinic on Dec. 24, 1947, his urine remained normal. *Duration* : 190 days.

Urine : albumin + +, macroscopic blood. She had no further fits after admission, and by Jan. 12, 1947, her blood pressure had fallen to 120/80 : the urine still contained albumin and red blood cells, but there was no longer obvious haematuria. Albumin and red blood cells were persistently present in the urine till March 8. Thereafter scanty red blood cells and traces of albumin were occasionally present. She was discharged on April 14. *Duration* : 67 days.

Anthisan Group: Moderate or Severe Cases

Case 12.—A girl aged 5 was admitted on June 21, 1948, with a history of having developed a sore throat two weeks previously. On the night before admission her face became puffy and she passed dark urine. On examination there was definite oedema of her face and slight oedema of her legs : follicular tonsillitis was present with enlarged tonsillar nodes. Physical examination was otherwise negative. B.P. 154/100. Blood urea 58 mg. per 100 ml. Urine : albumin + +, macroscopic blood, output in first 24 hours 12 oz. (340 ml.). A throat swab showed haemolytic streptococci.

Anthisan, 0.1 g. t.i.d., was given from June 21 to July 6. The oedema disappeared and the blood pressure rapidly returned to within normal limits. On July 1 her urine was free from albumin and no red blood cells or casts were seen on microscopic examination. She was discharged on July 6, and at her subsequent visits to the follow-up clinic on Aug. 16 and Sept. 28 she remained well and her urine was normal. *Duration* : 10 days.

Case 13.—A boy aged 9 was admitted on July 15, 1948, with a history of having developed a sore throat two weeks previously. Eleven days later he complained of headache and sickness, and his urine was dark brown in colour. Two days before admission his face became swollen and his urinary output was considerably diminished. On examination he was drowsy, and oedema of his face and sacrum was noted; his tonsils were enlarged and inflamed and the tonsillar nodes were palpable; no other abnormality was detected. B.P. 130/108. Blood urea 138 mg. per 100 ml. Urine : albumin + +, 20 red blood cells per high-power field (uncentrifuged specimen), output 13 oz. (368 ml.) in first 24 hours.

He was given anthisan, 0.1 g. four-hourly, from July 15 to 23. His oliguria persisted, and on July 18 his blood pressure rose to 158/120 and he developed a series of convulsions. He had another short convulsion on July 20, but next day his urinary output increased and his blood pressure began to drop. He had no further convulsions, but still complained of headache and vomited occasionally. By July 28 he was symptom-free, his blood urea was 41 mg. per 100 ml., his blood pressure 130/75, and his urine showed no abnormal constituents. He was discharged on Aug. 10. *Duration* : 13 days.

Case 14.—A boy aged 7 was admitted on Sept. 29, 1948, with a history of puffiness of his face and haematuria for three days. Three weeks previously he had complained of a sore throat accompanied by earache. On examination oedema of his face and ankles was present; his throat and ears were healthy and no other abnormality was found. B.P. 150/116. Blood urea 25 mg. per 100 ml. Urine : albumin + + +; macroscopic blood.

Anthisan, 0.1 g. t.i.d., was given from Sept. 29 to Nov. 11. On Oct. 6 his urine was still smoky and contained albumin, but his oedema had subsided and his B.P. was 110/70. On Oct. 20 the albuminuria had cleared up and no red blood cells were present on microscopical examination. Routine examinations of his urine since Oct. 20 have on only two occasions shown an abnormality. Once a trace of albumin was noted, and five days later 6 red blood cells per high-power field were found on microscopical examination. *Duration* : 21 days.

Case 15.—A boy aged 5 was admitted on Oct. 21, 1948, with a history of swelling of his face for six days. Three days before admission the swelling became more pronounced and was accompanied by headache and vomiting. There was no history of sore throat or haematuria. On examination his face was oedematous, his throat was infected, and his tonsillar nodes enlarged; no other abnormality was found. B.P. 150/110. Blood urea 45 mg. per 100 ml. Urine : albumin + +,

microscopic blood, occasional red cell and granular casts. His urinary output was normal.

He was given anthisan, 0.1 g. t.i.d., from Oct. 21 to Nov. 12. On Oct. 23 his urine contained no microscopical blood, but albumin was still present: the facial oedema had almost completely subsided. On Nov. 3 his urine showed no abnormality, and his blood pressure was 105/70. On only one occasion since Nov. 3 has a trace of albumin been found in his urine. *Duration*: 13 days.

Case 16.—A girl aged 6 was admitted on Oct. 22, 1948, with a history of swelling of her face and abdomen and some diminution in her urinary output for seven days. She had recently been a patient in the ear, nose, and throat ward of this hospital, suffering from otitis media, and had been discharged only seven days before her present admission. On examination there was some oedema of her face; her throat and ears were healthy. No other abnormality was noted. B.P. 185/145. Blood urea 60 mg. per 100 ml. Urine: albumin +, no cellular deposit, output 9 oz. (255 ml.) in first 24 hours.

She was given anthisan, 0.1 g. t.i.d., from Oct. 22. On Oct. 30 the blood pressure was 95/55; examination of her urine showed no abnormality, but her blood urea was still 60 mg. per 100 ml. On Nov. 12 the blood urea was 39 mg. per 100 ml. At the time of writing (Nov. 17) she is still having anthisan, and her urine has remained normal on daily examination. *Duration*: 20 days.

Case 17.—A girl aged 9 was admitted on July 5, 1948, with a history of vomiting and abdominal pain for three days. Physical examination on admission was negative, but her urine was found to contain albumin and a few pus cells. Three days after admission she complained of headache, and there was a suggestion of swelling of her face. Her blood pressure was 140/98. On July 10 she developed convulsions. B.P. 182/130. Blood urea 43 mg. per 100 ml. Her urinary output was 16 oz. (454 ml.) in 24 hours, and the urine continued to show albumin and a few pus cells with occasionally a few red blood cells.

Anthisan, 0.1 g. t.i.d., was given from July 11 to Aug. 3. On July 27 her blood pressure was 90/60 and her urine contained no abnormal constituents. Her urine remained normal until Aug. 27, when albumin and red blood cells were again found. Anthisan was again given in dosage of 0.1 g. t.i.d. from Aug. 27 to 31 and 0.1 g. four-hourly from Sept. 1 to 13. From Sept. 6 till her discharge on Oct. 29 no abnormality was found on daily examination of her urine, and her blood pressure and blood urea remained normal. *Duration of initial attack*: 16 days. *Duration of relapse*: 10 days.

Comment

After the first one or two cases had been treated with anthisan the clinical impression was formed that these cases were clearing up more quickly than would have been expected, and this impression became stronger as more cases were treated. A study of the figures given for the duration of the signs of activity in each case confirms this clinical impression, for not only is the average duration in the anthisan group (13 days) much less than that in the

control group (92 days) but if the mild and the moderate or severe cases are considered separately the least satisfactory case in the anthisan group has cleared up as quickly as the most satisfactory in the control group (see accompanying Table).

After the conclusion of anthisan treatment urine examination was made daily in every case up to the date of discharge from hospital, and occasional examination at the follow-up clinic thereafter.

In Case 17 the patient had a recurrence of albuminuria and microscopical haematuria after her urine had remained normal for one month. She was given another course of anthisan, and her urine again cleared after ten days; it has now remained normal for over two months.

In two other anthisan cases a trace of albumin was present on one occasion, and in one of these scanty red blood cells were seen on another occasion. All other urine examinations were normal.

It is of course too early as yet to speak of complete cure in any of the cases in the anthisan group, and all will be followed up so far as is possible. It seems probable, however, that as a general rule the longer signs of activity persist the greater are the chances of permanent renal damage. There would appear, therefore, to be reasonable grounds for hope that the further progress of the cases in the anthisan group will prove equally satisfactory.

Anthisan did not prevent the development of hypertensive convulsions in Case 13, in which they developed two days after the beginning of treatment. The patient's subsequent progress was, however, unusually satisfactory for such a severe case.

We have so far formed no definite opinions on optimum dosage or duration of treatment. In some cases the administration of anthisan was stopped when all abnormal signs disappeared; in others it was continued for a further week or two.

Acute nephritis is a disease which may run a very variable course, and with such a small series of cases it would obviously be unjustifiable and premature to advance any definite claims with respect to the efficacy of a particular line of treatment. Much further work will be necessary before the place of anthisan in the treatment of acute nephritis can be accurately assessed, and it is obviously desirable that this work should go forward as speedily as possible. Treatment with anthisan is simple, and toxic manifestations with this drug seem to be few and relatively unimportant. If its value in acute-nephritis can be proved a considerable advance in the management of this disease will have been achieved.

Summary

An account is given of the treatment with anthisan of eight cases of acute nephritis in children.

The course of these cases is compared with that of nine consecutive cases of this condition seen in the same hospital during the period immediately preceding the use of this treatment.

The duration of activity of the disease, and the abnormal findings in the urine, is notably shortened by treatment with anthisan than in those of the control group.

A recommendation for the building of a hospital of estimated cost of £38,000, has been passed by the Council. This first health centre will be expected to serve a population of about 20,000. There is to be five general practitioners. Eventually it is expected that between 40 and 50 health centres in the region of 15,000 people.

CEREBRAL EMBOLISM FOLLOWING CONTUSION OF THE HEART

BY

GERALD PARSONS-SMITH, O.B.E., M.B., M.R.C.P.

First Assistant

AND

DENIS WILLIAMS, M.D., D.Sc., F.R.C.P.

Assistant Physician

Neurological Department, St. George's Hospital

Damage to the heart resulting from non-penetrating blows to the chest wall is not rare, and several series of these cases have been recorded (Barber, 1944; Bright and Beck, 1935; Kahn and Kahn, 1929; Warburg, 1940; Hawkes, 1935; Arenberg, 1943; Sigler, 1945). The heart and pericardium, lying close behind the chest wall, are very vulnerable to severe blows in the region of the praecordium, but generally any damage which may be caused is mild and not recognized. In children and youths, however, there is perhaps a greater chance of cardiac trauma than in adults, because the heart is behind a resilient sternum and can be the more easily compressed against the spinal column. Although many cases of cardiac damage have been described we have not been able to find a case recorded in the literature in which a cardiac contusion was followed shortly afterwards by a cerebral embolism. As cardiac trauma may not be recognized as a cause of unexplained hemiplegia in childhood, since the condition has not been described before, and as several points arise from it, the following case is described in detail.

Case Report

The patient was a very robust, well-developed schoolboy aged 15½, who weighed 11 st. 5 lb. (72.12 kg.). He had lived in Tanganyika until he was 5, and whilst there had had several attacks of fever. He had otherwise been healthy, and in September, 1946, March, 1947, and March, 1948, had been found fit in routine school medical examinations. There was no history suggesting rheumatic fever.

The first incident occurred about one year before the present illness. In March, 1947, when he was boxing at school in a competition, the fight had to be stopped in the first round as he was in severe pain following concentrated punishment to the region of his heart. This pain, which was dull and aching character, continued for the next week or so. It was aggravated by exercise, and the patient remembered that he had to stop in a cross-country run and walk home because of the severe dyspnoea and pain in his left chest which the exercise had produced. After this there was no recurrence of the pain, and for the next year he played the various school games, of which football, with some distinction and without restriction. He had then taken part in competitive boxing on March 29, 1948, 2 parts in 5 when he fought the boy who had beaten him so thoroughly this estimated to be 28% (the measure-

the previous year. Again he received severe punishment to the left chest, and at the end of the first round he complained to his seconds of dull and sickening pain over his heart. The fight was stopped in the second round, as the boy was in agony. He thinks that he received only one glancing blow to the left side of his head, and he was in no way dazed or confused. The dull pain persisted, and some hours later he noticed a sharp pain, which from his description was pleuritic in type over his praecordium. He slept badly that night, but the next morning the pain was less, though he felt generally ill and very stiff. He took things quietly, as he found that exercise brought on the pain. On March 31 he had improved considerably but was still afraid to exert himself. During that afternoon he was sitting watching the boxing finals, when he became aware that his left leg had suddenly become dead below the hip and that he felt very faint. Two hours later his arm became affected, and shortly afterwards he had a general convulsion followed by confusion and headache. No further convulsion occurred, and during the next few days his condition was stationary.

He was admitted to St. George's Hospital five days after the injury. The boy was alert, right-handed, intelligent, and co-operative. The skull was normal in shape and was not tender. Neck movements were full and there was no limitation of straight leg raising. The cranial nerves were perfectly normal and in relation there was no papilloedema and no field defect. Speech was normal. On the affected left side the leg

was very spastic, there was ankle clonus, tendon jerks were increased, and there was an extensor plantar response. Voluntary movements and co-ordination were considerably impaired in the leg. The arm was similarly affected, but to a much smaller degree. Sensation was normal on full testing. The pulse rate was 80 and was irregular. The blood pressure was 130/70. There was no clinical enlargement of the heart. The heart sounds were distant and difficult to hear. A soft systolic murmur was heard over the mitral area, and a basal pericardial rub. Blood count was normal: red cells, 5,250,000; white cells, 6,800 per c.mm. with normal differential count. B.S.R., 2 mm in 1 hour (Westergren).

The blood Wassermann and Kahn reactions were negative. X-ray photographs of skull, heart, ribs, and lung fields showed no abnormality.

The electro-encephalogram on April 5 (Fig. 1, A) was abnormal. There was a low-voltage alpha rhythm of 10 c/s that underlay a generalized symmetrical abnormality which consisted of runs of high voltage 1 c/s and medium voltage 3-4 c/s. There was no evidence of focal abnormality, nor of one side being worse than the other. An electrocardiogram taken at the same time was also abnormal. The curve showed evidence of partial heart-block due to two distinct lesions. First, there was an occasional omission of auricular systole, though the auricular beats were for the most part regular. This would indicate some partial sino-auricular block. Secondly, the P-R interval was prolonged and variable (Fig. B). It varied from 0.2 to 0.4 second in length, which would indicate partial disturbance of conduction of the auricular system. The ventricular rate was 84. The T wave deflections in the three limb leads were normal.

FIG. 1.—(A) April 5, 1948. E.E.G. abnormal. A low-voltage alpha rhythm of 10 c/s underlies a generalized symmetrical abnormality consisting of runs of high-voltage 1 c/s and medium-voltage 3-4 c/s. (B) Electrocardiogram recorded from lead I on the electro-encephalogram. The E.C.G. shows evidence of sino-auricular block and varying conduction time. The paper speed and amplification in Fig. 1 were used for all the E.E.G. records.

He was kept in bed and given occupational therapy, with resultant improvement in the power of his left upper limb after a week, though the leg was still very spastic. The cardiac arrhythmia persisted, but the heart sounds improved in quality. The systolic murmur increased in intensity; it became harsh and occupied almost the entire systolic period. It was audible all over the praecordium, and was maximal in the left third and fourth interspaces $2\frac{1}{2}$ in. (6.25 cm.) from the mid-sternal line. The pericardial rub was heard only during the first two days in hospital.

An E.E.G. taken on April 13 showed a considerable change. Whereas there were generalized slow waves in the record taken on April 5, these persisted in the left hemisphere and there was suppression of all waves in the right parietal region (Fig. 2).

FIG. 2.—April 13, 1948. E.E.G. abnormal. Persistence of abnormal slow waves in the left hemisphere and suppression of all waves in the right parietal region. Recording as in Fig. 1

On May 4 an E.E.G. showed a slight improvement. A low-voltage dominant frequency of 12 c/s had returned. There were more 6 c/s waves on both sides, and runs of 3 c/s were seen which were more evident on the right than on the left. The records were still far from normal, but showed slight and gradual improvement (Fig. 3). Further E.C.G. recordings were

FIG. 3.—May 4, 1948. A low-voltage dominant frequency of 12 c/s is returning: 6 c/s are seen on both sides and runs of 3 c/s were more evident on the right than on the left. The records are still far from normal. Recording as in Fig. 1.

made, and these showed very little change. On May 4 an intramuscular injection of 1/50 gr. (1.3 mg.) of atropine sulphate caused an increase of pulse rate to 120, the rhythm became normal, and the P-R interval shortened to 0.16 second.

The hemiplegia continued to improve so that he was fit to be discharged from hospital on May 14. Since then his convalescence has been controlled and uneventful.

An E.C.G. taken on June 10 by Dr. Alastair Hunter (Fig. 4) was reported by him to show partial heart-block of varying character without the usual Wenckebach's periods. The auricular and ventricular complexes appear normal, but the auricular rate was not regular. It appeared, therefore, that

there was a disturbance of sino-auricular activity as well as A-V conduction. On Aug. 19, nearly five months after the injury, examination showed that improvement still continued. There were only residual signs of the hemiplegia, which caused him very little disability. The E.E.G. showed a further slight improvement, the records from the hemispheres being symmetrical. The heart was not enlarged, the sounds were of

FIG. 4.—June 10, 1948. E.C.G. showing disturbance of sino-auricular activity as well as A-V conduction.

good quality, and no murmurs were heard. The pulse was still irregular, rate 78. The E.C.G. still showed sinus and A-V block, but the P-R interval was shorter than had been seen previously and varied between 0.18 and 0.22 second. He was fully ambulant and was due to start on a sedentary engineering course of instruction.

Discussion

If a non-penetrating blow to the chest is severe enough there may be various cardiac sequelae. The commoner of these include pericarditis, myocardial damage including coronary thrombosis and rupture of the heart, alterations of rhythm, and disturbances of conduction. The clinical picture which results may in severe cases be similar to that seen in myocardial infarction and may be accompanied by the corresponding physical signs and electrocardiographic changes. Injuries of this type have been produced whilst playing various sports. These include cricket (Priest, 1939), football (Lee, Ussher, and Houck, 1943), steeplechasing (Anderson, 1940), golf ("Queries and Minor Notes," 1933), boxing (Jokl, 1941), and surf-bathing (Leinoff, 1940-1). Jokl (1941) reports that professional boxers have found that the effects of well-placed hooks to the heart last for a considerable period, usually for the rest of the fight. He also considers that chest injuries in boxers are very much more common than is generally assumed. In many cases there is no evidence of fracture of the thoracic cage, and there may be no bruising of the chest wall. Kellert (1917) cites the case of a man engaged in digging in a sandbank when it suddenly caved in and he was engulfed up to his waist. When dug out he was dead. A laceration 5 cm. in length extended through the interventricular septum. Rupture of the heart was described by Hamilton (1934) in a child of 7, and by Bilderbeck (1919) in a young Gurkha rifleman without any other evidence of trauma. Bagley and Osborn (1941) recorded a large contusion of the ventricle which caused death in five hours and was a lesion.

Experimental work has been performed on dogs by Fidler, and Koons (1937). The last-named author stated that the most frequent cardiac lesions following cardiac massage (1943) described bruising on the right auricle near the entrance of

tending to spread upwards. This type of lesion is of considerable significance in relation to disorders of rhythm, as it can readily spread towards the sino-auricular or auriculo-ventricular nodes. In the case in which death followed a blow from a cricket ball (Priest, 1939) the anterior surface of the heart was oedematous and bruised and there was a tear near the interventricular septum. In many cases the damage to the myocardium results in electrocardiographic changes similar to those of coronary thrombosis, though this is not invariable. Barber (1942) found an abnormal terminal complex in 12 out of 20 accident cases. Other changes were inverted P waves, supraventricular tachycardia, slurred R waves, and partial heart-block. In one case the P-R interval was 0.35 second five months after an accident. Rosenson (1924) recorded the case of a child of 10 who developed heart-block following a hard punch with the fist over the praecordium inflicted by one of his playmates, the E.C.G. returning to normal three months later. Wood (1948) describes the case of a woman aged 36 who had previously been healthy. In 1941 she was buried for one hour by a bomb explosion, and was almost asphyxiated. When examined shortly afterwards she was found to have a tremor in her left arm and also complete heart-block, both of which disabilities have proved to be permanent. Coffen, Rush, and Miller (1941) described the case of a patient aged 21 with auriculo-ventricular dissociation which developed after a chest injury received at the age of 3. Tuohy and Boman's case (1931) had bundle-branch block.

In the present case, a healthy boy received repeated heavy blows to his chest wall, following which signs and symptoms of cardiac damage were noted. These included severe pain in his left chest, pericarditis, a loud systolic murmur which was barely audible one month later, and evidence of partial heart-block. It is very probable that his heart had been bruised one year previously and was more susceptible to damage as a result of this. It is unlikely that both the sino-auricular and the auriculo-ventricular block were present before the injury. He had been medically examined previously on three occasions, and no comment was made about his cardiovascular system. The prognosis for the cardiac condition is uncertain. The diminution in the degree of heart-block following injection of atropine is a favourable finding, as is also the shortening of the P-R interval during the five months the boy has been under observation. Bruenn (1937) studied 22 patients with acute rheumatic fever who had impairment of auriculo-ventricular conduction time and found that intravenous injection of atropine sulphate abolished the conduction defect in 19. Acceleration in ventricular rate did not necessarily parallel decrease in conduction time. He concluded that in acute rheumatic fever the impairment of auriculo-ventricular conduction is due, in part at least, to an increase in "vagal tone" and that the site of this disturbance lies in the medulla.

There can be no proof of the site of origin of the embolus which caused the hemiplegia in this case, but in view of the other cardiac lesions it is possible that a small piece of a mural thrombus became detached. As the main was to the right auricle, for this to happen there either have been a spread of the bruising through to left auricle or else a septal defect. A localized pulmonary lesion is another possibility. In favour of this is the pleuritic type of pain which he had during the first few days after the blows, but against it are the negative x-ray appearances and absence of other symptoms of a pulmonary lesion. The third possibility is one of fat embolism from damage, but very careful radiology of the ribs and arm showed nothing suggestive of fracture. The hemiplegia, from its character, was clearly the result of an embolus, and the nature of the E.E.G. supports this view.

It is impossible to escape the conclusion that the embolus was the direct result of the myocardial damage which was so clearly demonstrated in the E.C.G., and that the actual cause of the embolus was a mural clot. The story of cardiac damage was obtained only by careful questioning after other causes for the hemiplegia had been excluded. The patient was an intelligent, observant boy, and the circumstances of his injury are dramatic. It is likely that the cardiac cause of other cases of hemiplegia in childhood may be obscured by the severity of the resulting hemiplegic picture. Although the E.C.G. produced striking changes in the present case, these are unusual, and if records are not made shortly after an injury evidence of it may be slight.

Sudden hemiplegia is not a common catastrophe in childhood. When not the result of direct brain injury, it usually occurs in the course of an acute infectious illness, particularly pertussis. Here it is the result of a haemorrhage, whereas in other infectious illnesses, such as pneumonia or diphtheria, it is thought to be embolic. Much attention has been paid in the past few years to cerebral venous thrombosis complicating infections or debilitating illnesses in children and giving rise to hemiplegia. Pyogenic infections bacterial endocarditis, and blood diseases, also the cause of embolic hemiplegia, were excluded in the present case.

The most frequent cause of a sudden hemiplegia in an apparently healthy child is congenital heart disease although, of course, the catastrophe is more likely to occur if bacterial endocarditis supervenes. There was nothing in the present case to suggest any congenital heart lesion; but the nature of the pathological process—an other wise normal child with an abnormal endocardium, mural thrombus, embolus, hemiplegia—differed only in that the heart lesion was acquired. Our case suggests that when all causes of sudden hemiplegia in childhood have been considered the possibility of unsuspected cardiac trauma should be raised.

Summary

A case is reported of a boy who sustained myocardial damage while boxing, with a resulting cerebral embolus. The electroencephalographic and electrocardiographic findings are related to the clinical findings.

A subcommittee of the Food Standards Committee of the Ministry of Food has been set up to consider the available evidence on the effect of ingesting foods contaminated with minute traces of metals or other injurious elements, and the possibility of prescribing limits for such contamination. A number of scientific bodies and research associations, including the Medical Research Council, are co-operating in the inquiry.

ANTI-HISTAMINE DRUGS IN TREATMENT OF NAUSEA AND VOMITING DUE TO STREPTOMYCIN

BY

J. R. BIGNALL, M.D., M.R.C.P.

AND

JOHN CROFTON,* M.D., M.R.C.P.

(From the Brompton Hospital)

Nausea and vomiting occur in a proportion of patients undergoing prolonged treatment with streptomycin (Heilman and others, 1945; Committee on Chemotherapeutics, National Research Council, 1946; Nichols and Herrell, 1946; Farrington and others, 1947; Streptomycin Committee of Veterans Administration, 1947; Medical Research Council, 1948). This toxic manifestation has been observed in 17 (35%) of 49 patients treated at the Brompton Hospital during the Medical Research Council trials of streptomycin in pulmonary tuberculosis, but in only four have symptoms been severe and persistent.

Such toxic symptoms as urticaria are probably due to hypersensitivity either to streptomycin or to impurities in the preparations used. It was thought that the nausea and vomiting might be caused in the same way and might therefore respond to antihistamine drugs. In the first few cases in which "benadryl" was tried there appeared to be some response, but the symptoms were too slight and transient to assess it accurately. It was possible to carry out controlled investigations in four patients with more severe toxic symptoms.

The symptoms were abolished or considerably reduced when benadryl capsules were given and returned when they were withheld.

Case Reports

Case 1.—A woman, aged 23, with bronchopneumonic pulmonary tuberculosis complained of transient nausea and vomiting on the 10th day of treatment with 0.5 g. of streptomycin hydrochloride six-hourly. Symptoms recurred on the 29th day and rapidly increased in severity. Ten days later the nausea was intense and she vomited after every meal. Benadryl, 50 mg., was given eight-hourly. There was an immediate response, and during the next seven days she had only slight early-morning nausea. Benadryl was discontinued; morning vomiting then returned, lasting for four days until the benadryl was resumed, when it ceased abruptly. Twelve days later benadryl was once more stopped; after three days the severe nausea and vomiting returned. Again benadryl had an immediate effect and the vomiting ceased.

Case 2.—A man, aged 23, with bronchopneumonic tuberculosis developed an urticarial rash on the 18th day of treatment with 0.5 g. of streptomycin hydrochloride six-hourly. On the 23rd day benadryl, 50 mg., was given, and this dose was continued eight-hourly for four days. The rash disappeared. Two days after stopping benadryl he complained of giddiness and vomited once. Benadryl, 50 mg., was given four-hourly and there was no further vomiting during the next two days. Benadryl was discontinued; four days later slight morning nausea occurred. The nausea increased whilst the giddiness decreased. After ten days benadryl was restarted in doses of 50 mg. eight-hourly. The nausea disappeared, but it recurred two days after benadryl was stopped. Three days later benadryl was again given and the nausea at once subsided.

Case 3.—A man, aged 49, with pulmonary tuberculosis and tuberculous bronchitis complained of abdominal discomfort and flatulence on the 10th day of treatment with 0.5 g. of streptomycin hydrochloride six-hourly. Five days later the symptoms became worse, particularly after the midday meal. Benadryl, 50 mg., was given at noon and 6 p.m. This controlled the afternoon abdominal discomfort, but five days later severe giddi-

ness and early-morning nausea developed. The nausea improved after the midday dose of benadryl. The dosage was increased to 100 mg. at 6 a.m. and 50 mg. at noon and 6 p.m. There was considerable improvement in the morning nausea, but the giddiness was unaffected. The nausea remained moderately well controlled, but several times the omission of a dose led to an immediate increase in the discomfort.

Control Tests

It seemed possible that suggestion might have played a part in the apparent response. Capsules identical with those containing the benadryl were filled with lactose. These were substituted for the benadryl capsules without the patients' knowledge. Each time the inert capsules were used the symptoms returned, but they disappeared when the capsules containing benadryl were resumed.

Case 1.—On the 74th day the patient had remained free from nausea and vomiting for three days with a dose of 50 mg. of benadryl eight-hourly. Lactose capsules were substituted. Next day the symptoms reappeared with their former severity and continued without remission for two days. The lactose capsules were withdrawn and benadryl capsules substituted. Vomiting ceased after the first dose. Thereafter benadryl was continued until streptomycin treatment ended on the 144th day; no further vomiting occurred, although there was occasional slight nausea. She remained free from toxic symptoms during the next seven weeks. A second course of streptomycin treatment was then started, and after three days the severe and persistent vomiting recurred. Streptomycin was discontinued, the patient's condition being too desperate to warrant its continuance.

Case 2.—On the 59th day the patient had remained free from nausea and vomiting for one day with a dose of 50 mg. of benadryl eight-hourly. Lactose capsules were substituted. The following day the nausea and vomiting reappeared and remained for three days. The lactose capsules were withdrawn and benadryl capsules substituted. There was no further nausea or vomiting. Twice more, on the 76th and 91st days, benadryl was discontinued without substitution of inert capsules; the symptoms recurred within two days and each time ceased abruptly when benadryl was restarted. On the 98th day lactose capsules were again substituted. Symptoms reappeared two days later and disappeared rapidly when the benadryl capsules were resumed. Thereafter there was no further vomiting or nausea, benadryl being stopped at the time of the last streptomycin injection on the 123rd day.

To eliminate the slight sedative action of benadryl as a cause of the response a similar experiment was carried out with identical capsules containing $\frac{1}{2}$ gr. (32 mg.) of phenobarbitone. Substitution of these for the benadryl capsules was followed by immediate exacerbation of the symptoms, and resumption of benadryl capsules by an equally dramatic return to the original condition.

Case 3.—On the 90th day the nausea and vomiting had been moderately well controlled for over eight weeks with a dose of 100 mg. of benadryl at 6 a.m. and 50 mg. at noon and 6 p.m. Substitution of phenobarbitone capsules began at the evening dose. The following morning there was considerably increased nausea and the patient vomited once. The severe nausea lasted two days. Benadryl was then resumed and the nausea decreased after the first dose. Thereafter slight occasional nausea remained up to and beyond the end of streptomycin treatment. The dose of benadryl was gradually reduced, but four weeks after stopping streptomycin there was still slight morning nausea when the benadryl dose was omitted. The severe giddiness was still present.

The experiment was repeated in another case with similar results, both benadryl and "antistin" being used. This was the only one of the severe cases of nausea in which it was possible to withdraw antihistamine drugs before the end of streptomycin treatment.

Case 4.—A woman, aged 20, with bronchopneumonic pulmonary tuberculosis complained of slight giddiness 21st day of treatment with 1 g. of streptomycin by

*In receipt of a grant from the Medical Research Council.

single daily injection. On the 27th day slight morning nausea appeared and four days later she began to vomit. Benadryl, 50 mg. eight-hourly, was started on the following day. During the next twelve days there was no nausea and she vomited only once. Identical capsules containing phenobarbitone were substituted. Twenty-four hours later the vomiting reappeared. The next day the same capsules containing 100 mg. of antistim were substituted; vomiting ceased after the first dose. Antistim in tablet form was continued for ten days. After its withdrawal neither nausea nor vomiting reappeared and she remained free from these symptoms throughout the remainder of the 32 weeks of streptomycin treatment.

In at least three of these cases we would have had to stop the streptomycin if we had not been able to control the nausea and vomiting. With the continuous administration of benadryl it was possible to complete the full four-months course. We would emphasize, however, that giddiness due to streptomycin was not relieved by the antihistamine drugs.

Summary

Antihistamine drugs were found to relieve the nausea and vomiting which sometimes occur during treatment with streptomycin. This conclusion was supported by control tests in four severe cases. Giddiness due to streptomycin was not relieved.

We are grateful for the co-operation of the physicians of the Brompton Hospital under whose care the patients were admitted. We also wish to thank the hospital pharmacists for help with the control tests and Messrs. Parke, Davis and Co. for a supply of empty capsules.

TETANY FOLLOWING REMOVAL OF A PARATHYROID ADENOMA WITH BONE DISEASE: FINALLY ALLEVIATED WITH CALCIFEROL

BY

NANCY S. CONWAY, M.B., Ch.B.

Hall Tutorial Fellow in Medicine, University of Glasgow
(From the Gardiner Institute of Medicine, University of Glasgow, and the Western Infirmary, Glasgow)

When a parathyroid adenoma has caused extensive bone disease its removal is followed by severe tetany. This report illustrates the value of calciferol and the uselessness of parathormone in the treatment of such a case.

Case History

The patient, a woman aged 43, was admitted on June 1, 1947, with backache dating from 1940 and general weakness which had caused her to become bedridden. She had kyphosis and sacral deformity, and radiographs revealed extreme decalcification of the entire skeleton. The blood calcium was 12.2 mg. per 100 ml., phosphorus 3 mg. per 100 ml.; alkaline phosphatase 45 King-Armstrong units per 100 ml., and urea 32 mg. per 100 ml.

A diagnosis of hyperparathyroidism was made, and on July 15 Professor C. F. W. Illingworth removed a small adenoma from one parathyroid gland.

After operation the serum calcium fell abruptly (Fig. 1) and tetany developed. Parathormone was started on the day after operation. 60 units being given intramuscularly. The dose was

increased until 200 units were given daily, but no rise in the serum calcium occurred even after the initial doses. During this period the patient received intravenous calcium gluconate (10-20 ml. of a 20% solution two or three times a day) and 12 g. of calcium lactate orally per day. In order to facilitate

FIG. 1.—Showing the immediate fall in the calcium and phosphate in the phosphatase which occurred after operation. During administration of calciferol the calcium and phosphate gradually rose, and the phosphatase fell to normal.

absorption of calcium a low phosphorus diet (0.56 g.) and 40,000 units of calciferol were given daily. In spite of these measures the patient's condition rapidly deteriorated. In addition, she became uncooperative, refusing to have injections, and parathormone was stopped on the 14th post-operative day, when the serum calcium was still less than 5 mg. per 100 ml. As a last resort a transfusion of 2½ pints (1.42 litres) of fresh citrat

FIG. 2.—Showing rise of blood urea after operation and during calciferol treatment. It fell again after cessation of the drug.

blood (Group A) was given. The result was disastrous. Four hours later tetany, more severe than had hitherto occurred, developed, although examination of the blood showed that there had been no further drop in calcium.

An attempt was then made to raise the serum calcium by increasing the daily dose of calciferol to 300,000 units (6 oste tablets, each of 50,000 units). Three days later definite improvement was noted; thereafter the serum calcium gradually rose (Fig. 1), and signs of tetany disappeared and were not again elicited. At no time did the patient show any intolerance to the calciferol, which was stopped on Oct. 22 after a total of 19,000,000 units had been given. The blood urea, however, which rose after operation, remained high until some time after the drug had been stopped (Fig. 2). The patient was discharged.

TABLE I.—The Serum Calcium, Phosphate, and Alkaline Phosphatase after Cessation of Calciferol Treatment

Date	Serum Calcium (mg./100 ml.)	Serum Phosphate (mg./100 ml.)	Serum Alkaline Phosphatase (King-Armstrong Units per 100 ml.)
30/10/47	9.1	4.0	10.2
21/11/47	8.6	3.8	—
19/12/47	8.5	—	9.0
16/1/48	10.2	3.5	8.6
24/2/48	8.8	3.1	—
10/3/48	9.0	3.2	8.6

on Oct. 31, and since then the blood chemistry has remained satisfactory (Table I). In March, 1948, she was symptom-free, had gained 30 lb. (13.6 kg.) in weight, and was able to walk unsupported.

Discussion

The post-operative tetany was due to an abrupt fall in serum calcium. Efforts to raise the latter by parathormone (total 1,260 units) were unsuccessful even with different batches of the extract. That it was physiologically active was certain, since its effect in producing a diuresis was well marked. It was felt that failure to absorb calcium might account for the lack of response to the hormone, but faecal analysis for calcium showed that this was not so. It was concluded that the fall in serum calcium and the resultant tetany were due not to too little parathyroid tissue but to the "hungry bones" (Cope, 1941). After operation the decalcified skeleton absorbs calcium and phosphorus from the plasma with so much avidity that hypocalcaemia and hypophosphataemia result. The biochemical findings support this theory, the blood calcium and phosphorus both falling immediately after operation. The rise in alkaline phosphatase which occurred is interpreted as being due to increased osteoblastic activity associated with this recalcification.

The severe and almost fatal tetany which followed the transfusion of blood was produced in a different way. The introduction of citrate (the anticoagulant) would on account of its avidity for calcium ions cause a further reduction in the ionized calcium without altering the total calcium. "Citrate tetany" has been produced experimentally, but its occurrence after transfusion must indeed be rare unless, as was the case here, the serum calcium is already depleted.

The rise in serum calcium which started three days after large doses of calciferol had been prescribed was due to the specific effect of the drug and not to a spontaneous recovery, since the calcium fell again when the dosage of calciferol was temporarily reduced (Fig. 1). During its administration, also, the serum phosphorus rose slowly, while the alkaline phosphatase fell with remarkable rapidity and was normal eight weeks after operation. The calciferol did not appear to have any inhibitory effect on deposition of calcium or phosphorus in bone, for during a five-weeks period 69.25 g. of calcium and 14.84 g. of phosphorus were retained.

Not every case of parathyroid adenoma will require massive calciferol therapy in the post-operative phase. It will definitely be indicated when there is well-marked bone disease and should be started immediately after removal of the adenoma. In addition, large doses of calcium must of course be given orally, and until the calciferol takes effect symptoms of tetany may be alleviated by intravenous calcium gluconate; parathormone should not be used.

I wish to thank Professor C. F. W. Illingworth for allowing me to investigate this patient and Professors J. Norman Davidson and F. W. McNee for advice in the preparation of the paper.

Cope, O. (1941). *Ann. Surg.*, 114, 706.

The Ministry of Health has issued a pamphlet, "Nursing and Domestic Staff in Hospitals," intended as a guide to hospital management committees on the recruitment, training, and conditions of service of nurses. It includes an example of how to work a shift system in a ward of 34 beds with a staff of one sister, two staff nurses, seven students for day duty, and two nurses for night duty, as well as some observations on what the proper task of a nurse should be and how some of the ward duties at present performed by nurses could be undertaken by domestic orderlies. These include arranging flowers, answering telephones and running messages, preparing meal trays, and handling clothing and laundry. The pamphlet has been sent to boards of governors of teaching hospitals and hospital management committees.

AGGLUTININ ANTI-P IN PREGNANCY REPORT ON TWO CASES

BY

I. DUNSFORD

(From the National Blood Transfusion Service, Sheffield)

The detection of an antibody in the serum during pregnancy has had much significance since Levine and his co-workers (1941) first propounded the theory (since amply confirmed) that haemolytic disease of the newborn is caused by the action on the foetal erythrocytes of immune antibodies formed in the mother's serum during pregnancy and passed through the placenta into the foetal circulation. The formation of these antibodies is stimulated by an antigen present in the foetal red cells but absent from the maternal red cells, the antigen having been inherited from the father. In a very large proportion of cases it has been demonstrated (Boorman *et al.*, 1942) that the rhesus complex has been involved, and in a few the ABO system (Aubert *et al.*, 1945).

There are not many references in the literature to immune or naturally occurring anti-P, and a leading article in the *British Medical Journal* of Oct. 20, 1945 (p. 535), refers to a case in which anti-P was associated with pregnancy. Wintrobe (1946) states: "In rare cases iso-immunization apparently occurs against the agglutinogens A and B, and possibly even M and P may cause immune bodies to be formed." Nigg (1930) has described two human sera which were later found to contain natural anti-P iso-agglutinins, whilst Wiener (1943) records having found only three or four such sera during a period of ten years. The latter serologist also found this iso-agglutinin in two post-transfusion sera he investigated; he states that "while the possibility exists that this factor could on rare occasions give rise to haemolytic transfusion reactions, to date no such reactions have been reported."

During the course of routine investigations carried out in this laboratory, which included testing the patient's serum at 37° C. against a series of Group O cells chosen not only for their rhesus type but also for their M, N, P, Kellecher, Lewis, and Lutheran types, the agglutinin anti-P was discovered in the sera of two pregnant women. In view of the extreme rarity of such an occurrence the history and the serological findings in these two cases are presented below.

Case 1

Mrs. X, a 2-gravida aged 36, in 1940 had a full-term clinically normal child weighing 6 lb. 12 oz. (3.06 kg.), and was again due for delivery on July 31, 1947. There was no history of transfusion or injection of blood. A blood sample was sent from the antenatal clinic for rhesus typing.

Serological Findings

March 7.—Mrs. X:—Group O Rh-positive. Her serum agglutinated some Group O cells weakly at 37° C., giving much stronger reactions at room temperature and at 4° C. At the latter temperature it appeared specific for P cells with a titre of 4. These reactions were compared with those of a proved anti-P serum and were found to be identical, suggesting that Mrs. X's serum contained anti-P. The serum gave a strong Diamond (Diamond and Abelson, 1945) slide reaction. A sample of serum was submitted to the Blood Group Reference Laboratory, Lister Institute, and confirmed as anti-P.

May 9.—Mrs. X:—Group O; genotype CDe/cde; M, N, p. The titre of the antibody against the same Group O P cell was 16 at room temperature and there was no evidence of enhancing when pooled serum from Group O persons was used in place of saline. **Mr. X:**—Group A Rh-positive; genotype CDe/cDE; M, N, P. His cells were strongly agglutinated by his wife's serum at 4° C. and at room temperature, and weakly at 37° C after absorption with

June 20.—Mrs. X:—The titre of the anti-P was 16 with the standard O P cell. There was no

incomplete anti-P after destroying the complete antibody by heating at 70° C. for ten minutes and using the Coombs test (Race *et al.*, 1946) for incomplete antibodies.

Aug. 12.—Mrs. X was delivered of a normal infant. *Baby X*:—Group A Rh-positive; M, N, P. Direct Coombs negative. The mother's serum after absorption with A p cells agglutinated the baby's cells strongly at 4° C. and room temperature and weakly at 37° C. *Mrs. X*:—The titre of the antibody was 8, and it could not be enhanced.

Aug. 22.—The child was clinically normal and the haematological reports were normal. On the tenth day of Mrs. X's puerperium the titre of the antibody was 32 at room temperature and was confirmed by the Blood Group Reference Laboratory as anti-P.

Case 2

Mrs. Y, a primipara aged 27, was expecting delivery on Sept. 6, 1947. There was no history of transfusion or injection of blood. A blood sample was sent from the antenatal clinic for rhesus typing.

Serological Findings

March 8.—Group O Rh-positive (D+) p. Her serum agglutinated some O cells weakly at 37° C., but gave much stronger reactions at room temperature and at 4° C. At the latter temperature it appeared specific for P cells with a titre of 4. These reactions were compared with a proved anti-P serum and Mrs. X's serum (previously described) and were found to be identical. From this it appeared that the antibody was anti-P; a sample of the serum submitted to the Blood Group Reference Laboratory was confirmed as anti-P.

April 21.—The titre of the antibody was 32 at 4° C. and room temperature with standard Group O cells and there was no evidence of its enhancement. The titre at 37° C. was 2. There was no evidence of an incomplete anti-P.

June 28.—Mrs. Y's cells were fully investigated: Group O Rh-positive; genotype CDe/cde; M, N, p. The titre of the antibody had not changed.

Aug. 2.—No change in the strength of the antibody.

Aug. 26.—Mrs. Y was delivered of a normal baby. *Baby Y*:—Group O, apparently Rh-negative; P. Direct Coombs negative. Its cells were agglutinated by the mother's serum at 4° C., room temperature, and 37° C. *Mrs. Y*:—No change in the strength of the antibody, nor could it be enhanced.

Sept. 5.—Mrs. Y:—No change in the strength of the antibody. *Baby Y*:—Haematological reports normal; no signs of haemolytic disease of the newborn.

Discussion

The finding of these antibodies in the sera of two pregnant women immediately raises the questions: Are these antibodies immune or naturally occurring? and, Can they give rise to haemolytic disease of the newborn? The following criteria were used in order to arrive at a decision: (a) Could the titre of the antibody be enhanced? (b) Was there evidence of an incomplete form of the antibody? (c) The direct Coombs test on the infants' red cells. (d) The clinical condition of the children.

In investigating the possibility of enhancing the antibody titre the technique used was that first described by Boorman and Dodd (1945). They found that immune sera could be enhanced when normal human sera were used as the diluent in place of saline, whereas naturally occurring agglutinins showed no enhancing. Boorman and Dodd applied their technique to 81 immune and 14 naturally occurring agglutinins and included in their series cold agglutinins but not anti-P. Their technique has been confirmed in this laboratory. Although there were fluctuations in the titre of the antibodies in the two cases described, there was no evidence of enhancing when pooled human serum from Group O p donors was used as the diluent.

In cases of Group O people whose anti-A has been stimulated as a result of immunization with A-group-specific substance it has been shown that their sera contain an

incomplete form of the alpha agglutinin (Boorman and Dodd, 1946). This could be detected by destroying the complete agglutinin with heat and the finding of the incomplete form by the Coombs reagent. In the two sera here reported the complete agglutinin was destroyed by heating at 70° C. for 10 minutes and there was no evidence of an incomplete form of anti-P in that P cells were not sensitized when tested with Coombs reagent.

The second use of the Coombs reagent is for the detection of *in vivo* sensitization by a maternal antibody of the red blood cells of infants with haemolytic disease. These sensitized cells are agglutinated by an anti-human-globulin serum, whereas the cells of normal infants are not agglutinated. In the two cases here described the red cells of the infants were tested as soon as possible after birth and there was no evidence of sensitization. Finally, the medical officers in charge of the cases reported that the infant showed no clinical signs of haemolytic disease and developed normally.

These investigations suggest that the anti-P agglutinin were of natural occurrence and may be compared to the naturally occurring agglutinins anti-A and anti-B, which have occasionally been responsible for haemolytic disease of the newborn. The protective factors in heterospecific blood group pregnancies were studied by Tovey (1945). His assessment of the main mechanisms operating individually or in combination to protect the foetus may apply to these cases—namely, lack of permeability of the human placenta to these agglutinins, neutralization of the incompatible antibody crossing the placental barrier by group-specific substances in the foetal plasma, lack of sensitivity of the foetal erythrocytes towards the incompatible agglutinins, and diminished activity of the agglutinins at body temperature.

It would appear from these two cases that naturally occurring anti-P, although of sufficient strength to be active at 37° C. (Kettel, 1930: the thermal amplitude is usually directly proportional to the titre of the cold agglutinin), is unlikely to be a causative agent in haemolytic disease of the newborn. Conclusive evidence may be derived from further studies.

Summary

Two cases of pregnant women in whose sera the agglutinin anti-P was found are reported.

Evidence suggesting that these antibodies were of natural occurrence is offered.

It is suggested that this naturally occurring antibody is not of pathological significance.

The serological investigations were carried out in the laboratory of the National Blood Transfusion Service, Sheffield, and my sincere thanks are offered to the late and present blood transfusion officer (Dr. E. F. Aubert and Lieutenant-Colonel R. H. Malone) for their discussions and for permission to publish this paper. To Drs. J. B. Cochrane and R. G. Cooke, of Nottingham City and Derby City Hospitals, for their co-operation, and to Drs. A. E. Mourant and R. R. Race, of the Lister Institute, for their confirmation of the anti-P sera.

THE HUMAN LOUSE IN TRANSMISSION OF *T. DUTTONI* IN NATURE

BY

R. B. HEISCH, M.D.

(From the Division of Insect-Borne Diseases, the Medical Research Laboratory, Kenya)

Hitherto there has been no evidence that the human louse can act as a vector of *Treponema duttoni* in nature. Even in the laboratory Nicolle and Anderson (1927) were unable to infect lice with a Congo strain of the parasite. Recently, however, Heisch and Garnham (1948) have shown that under laboratory conditions several strains of East African *T. duttoni* can infect and undergo metacyclic development in lice, and that the infection can be transmitted by inoculation.

The present paper reports the discovery of natural infections in lice of spirochaetes indistinguishable from *T. duttoni*. The only other worker to have experimented along these lines is Blanchard (1914), who in the Congo inoculated mice with lice collected from patients infected by *T. duttoni*, but with negative results.

Lice were collected from the clothes of patients infected with *T. duttoni* at Kisumu and other places in Kenya Colony where the disease is endemic, after being kept for varying periods they were emulsified with saline and inoculated into rats and mice. Lice were collected from seven patients, and four of the batches proved infective.

Case 1—Ten lice (L19) were collected on Aug. 26, 1946 from the clothing of a Kikuyu woman with *T. duttoni* in her blood. The following day one louse was smeared on a slide and stained; no spirochaetes were seen. On the 28th seven lice remained, these were emulsified and inoculated into Mouse 673 but infection did not result.

Case 2—At Meru six lice (L26) from the clothing of a child aged 1 year with relapsing fever were emulsified and inoculated into Mouse 1460 but no infection resulted.

Case 3—Sixteen lice (L26) from the trousers of a sophisticated Tanganyikan suffering from relapsing fever and with quite numerous spirochaetes in his blood, were emulsified and inoculated into Mouse 1593; there was no infection.

Case 4—Eight lice (L30a) were collected at Kisumu from the clothes of a patient with spirochaetes in his blood. Six hours later they were emulsified and inoculated into Rats 2574 and 2548, both of which became infected.

Case 5—Two lice (LKu8) were removed from the head of a child of the Jaluo tribe at Kisumu with spirochaetes in his blood. After five hours they were emulsified and inoculated into Rat Ku19, which subsequently became infected.

Case 6—Forty-eight lice (LKu9) were collected from an adult male of the Jaluo tribe at Kisumu with relapsing fever spirochaetes in his blood. Twenty-five of these were inoculated into a rat after forty-eight hours and the remaining 23 were inoculated into Rat Ku24 after seventy-two hours. Both these animals became infected.

Case 7—Sixteen lice (LKu10) from the clothes of a Jaluo male aged 18 with spirochaetes in his blood were emulsified and inoculated after twenty-seven hours into Rat Ku25, which subsequently became infected.

Discussion

The recovery of spirochaetes from four out of seven batches of lice collected from patients infected with *T. duttoni* is further evidence that the louse is able to act as a vector of this organism in nature. It might be objected that the infections caused in mice and rats were examples of mechanical transmission, but this seems unlikely, as the lice were kept for periods up to three days before inoculation. The criticism might also be made that the strains recovered were in reality not *T. duttoni* but some other

species of spirochaete. However, the strains proved to be *T. duttoni*, because they were capable of infecting *Ornithodoros moubata*, they caused typical infections in laboratory animals, and they were markedly neurotropic (residual brain infections in rats and mice).

It is strange that epidemics of louse-borne *T. duttoni* have rarely if ever been known to occur. This may be due to the existence of an immunity in the populations of endemic areas or because the louse is a less efficient vector of *T. duttoni* than of *T. recurrentis*.

Summary

Of seven batches of lice collected in Kenya Colony from patients infected with *T. duttoni* four were found to be infective when inoculated into rats and mice.

The spirochaetal strains recovered proved to be *T. duttoni* and not any other species of spirochaete.

Although it is probable that the louse can act as a vector of *T. duttoni* in nature, it is not known how often or with what degree of facility this occurs.

I have to thank the Director of Medical Services, Kenya, for permission to publish this paper. I am also much indebted to Mr W. E. Grainger for helping me with the transmission experiments.

MENINGOCOCCAL CONJUNCTIVITIS

BY

J. D. A. GRAY, M.B., F.R.C.P.Ed., D.P.H.

AND

R. A. LAMBERT, A.I.M.L.T.

(From the Central Middlesex Hospital)

An intracellular Gram-negative diplococcus in the exudate of a purulent conjunctivitis is often assumed to be a gonococcus, but full bacteriological investigation sometimes shows it to be a meningococcus. There are numerous references in the literature to the presence of meningococci in the conjunctiva, but the methods of identification employed in the earlier cases, at least, are not now acceptable.

Case Report

A boy aged 34 years attended the casualty department with a gross purulent conjunctivitis of the left eye of one day's duration. The cornea was clear and the interior of the eye normal. The condition was completely cured within eight days by local treatment with 30% sulphacetamide ('albacid') hourly, penicillin in saline (2 000 units per ml) every half hour, atropine, and the provision of coloured glasses. The right eye was healthy.

Bacteriology—When first seen films from the left eye showed pus cells with numerous intracellular and extracellular Gram-negative diplococci, and cultures yielded a copious growth of these and a scanty one of *Staphylococcus aureus*. The Gram-negative cocci were strict aerobes, grew only on media containing blood or serum, and fermented glucose and maltose but not lactose or saccharose. Their colonies were denser and more luxuriant than those of gonococci. Agglutinations of them were agglutinated to titre by Laboratory 5 (Griffith) Group II meningococci to 1 in 25 by Griffith's Group I antiserum. It was therefore identified as *Neisseria meningitidis* (Griffith Group II). The right eye did not yield meningococci. The right eye did not yield meningococci. The pharynx of the patient, his parents, and his siblings were examined for neisseriae without success.

THE

WASH. G.
PRINCIPLES OF

Discussion

During or immediately preceding cerebrospinal meningitis, meningococci have often been found in the conjunctiva. In some instances the eyes were apparently healthy (Randolph, 1893; McKee, 1908, 1909), but others showed a purulent conjunctivitis (Koplik, 1904). This type of conjunctivitis has become progressively rarer with treatment by specific antiserum and later by sulphonamides, so that it is now practically never observed (Lewis, 1931; Tillett and Brown, 1935). McKee (1908) discussed the probabilities of whether the conjunctiva acted as a portal of entry for the neisseriae or became invaded secondarily.

The occurrence of the conjunctivitis immediately before the onset of meningitis (Koplik, 1904) and its appearance in nurses attending patients with meningitis (Smith, 1905; Reese, 1936) support the first contention. There is no inherent reason why the conjunctiva should not, like the nasopharynx, harbour and even be infected by air-borne meningococci, but obviously the chance is less, inasmuch as a current of air containing the organisms is not drawn by each respiration over the conjunctiva. Meningitis resulting from meningococci which have gained access to the body via the conjunctiva, if it occurs at all, must be very rare compared with the usual sequence of events described by Wilson and Miles (1946), beginning with entry of the meningococci into the nasopharynx and their spread to the meninges either direct or by the blood stream.

Conjunctivitis due to *N. meningitidis*, unassociated as in this case with meningitis in either the host or any of his known immediate contacts, has often been recorded, and Stuart and McWalter (1948) give more than a dozen references. They themselves described six cases, from which they isolated five strains. Four of these were investigated serologically and, in contrast to the case here recorded, all belonged to Group I. It is a matter for speculation whether in the absence of treatment these patients would subsequently have developed meningitis. At present meningitis is usually due to Group I, and most of the strains found in the nasopharynges of persons who have not been in contact with cases of meningitis belong to Group II (Mackie and McCartney, 1948).

In the interests of public health as well as of the patient himself, rapid identification of the organism in neisserial conjunctivitis is of obvious importance. Difficulties due to absence of facilities for immediate culture may be overcome by the use of the thioglycollate method of transport (Stuart, 1946). As Stuart and McWalter suggest, meningococcal conjunctivitis is more frequent than commonly imagined, is often erroneously diagnosed as gonococcal, and may be as severe clinically as gonococcal ophthalmia. Although both conditions respond to sulphonamides, the sociological "follow-up" required is entirely different.

Summary

A case of purulent conjunctivitis due to *N. meningitidis* Group II is recorded and discussed. Contacts were examined for neisseriae without success.

Our thanks are due to Drs. A. Rugg-Gunn and H. Claff for the clinical details.

Medical Memoranda

Pulmonary Tuberculosis Complicated by Amoebic Hepatitis

The following case history may be of general interest because of its differential diagnostic problem, which is somewhat unusual, and its moral, which is becoming increasingly common.

CASE HISTORY

The patient, a married woman aged 36, has been suffering from pulmonary tuberculosis for at least ten years. A left-sided artificial pneumothorax was induced some two years ago, and she recently came for treatment of a fresh spread in the right lung. She had had appendicectomy twenty years ago.

For the last eight years she has been complaining of sharp, dragging pains in the right iliac fossa and lately also in the right epigastric region; the pains were independent of food, were worse when she stood up, and had grown in intensity during the last few years. There was moderate flatulence, but the bowels were regular and the stools macroscopically normal. She gave a vague history of three or four sharp attacks of diarrhoea in the course of the last nine years. The first attack, lasting four or five days, was in 1939; the others, lasting two or three days, occurred between 1935 and 1944. She thinks that on two occasions she passed some blood and mucus.

The patient has never been in tropical countries, and, apart from occasional pre-war trips to Paris and the South of France, her only foreign journey was a summer cruise in Dalmatian waters in 1937. The abdominal symptoms had been variously diagnosed as those of duodenal ulcer and abdominal tuberculosis. They have not responded to treatment.

On examination the caecum was ballooned, doughy and tender and could be elicited by pressure on the colon as far as the splenic flexure. No mass or rolled-up omentum could be palpated. A small area of localized tenderness, which had been unknown to the patient, could be detected in the right lobe of the liver, about 1 in. (2.5 cm.) to the right of the xiphoid process. This tenderness was more pronounced in the intercostal space above than on the palpable liver-edge. On screening, the right diaphragm was observed to be slightly elevated and its movement was somewhat diminished. Sigmoidoscopy disclosed a congested oedematous rectal mucosa, severe submucous haemorrhages on the haustra, and a few small round healed ulcers, at 4 in. (10 cm.).

Investigation revealed slight hypochromic anaemia; W.B.C. 3,600 with normal distribution; van den Bergh quantitative test, 0.8 mg. per 100 ml.; nicotinic acid tolerance (Erdei, 1947, 1948), 450 mg. galactose tolerance and thymol turbidity normal; cephalin-cholesterol test, weakly positive. On examination of the faeces two typical *Entamoeba histolytica* cysts could be demonstrated in the sixth specimen.

A course of ten injections of emetine, with concurrent penicillin and diodoquin and consecutive emetine bismuth iodide and carbarsol was given. After the second emetine injection the liver became very tender, but all tenderness disappeared after the sixth injection, thus justifying the diagnosis of chronic amoebiasis with hepatitis.

Further attacks of diarrhoea occurred some time after the improvement from the anti-amoebic treatment. First *Giardia lamblia* was demonstrated; afterwards, when the diarrhoea became worse and sigmoidoscopy revealed superficial ulceration of the rectal mucosa, *Shigella flexneri* (Newcastle-Manchester strain) was grown from sigmoidoscopy swab. Several stool cultures proved to be negative. Sulphasuxidine treatment was given, and the patient is now free of the complaint, and her motions do not exceed two daily.

COMMENT

In the above case abdominal tuberculosis figured much to prominently in the differential diagnosis, and the correct diagnosis was arrived at only because it was realized that chronic amoebiasis is an increasingly common condition which must be considered when dealing with a very wide range of abdominal and general conditions. This case also demonstrates the value of a rapid liver-function test such as that of nicotinic acid tolerance.

Reviews

COLON AND RECTUM

The Surgery of the Colon and Rectum. By Sir Hugh Devine, M.S., F.R.C.S., F.R.A.C.S., F.A.C.S., and John Devine, M.S., F.R.C.S., F.R.A.C.S., F.A.C.S. (Pp. 373; 277 illustrations (some in colour). 52s. 6d.) Bristol: John Wright and Sons. 1948.

The work of Sir Hugh Devine in advancing the surgery of the large bowel is already well known. With John Devine as a collaborator in writing this new book he offers all the wisdom which a wide experience of this realm of surgery has developed in an alert and inventive surgeon. We believe this to be an important book which will be highly valued and appreciated by operators both young and old.

Perhaps the outstanding lesson of these pages is that the mortality of colonic operations could be reduced considerably if the bowel were "defunctioned" by an adequate colostomy and chemotherapeutically prepared to reduce possible infection to a minimum. This is, of course, no more than a reiteration of the teachings of Paul and Mikulicz, but the technique has been improved by performing a more perfectly designed colostomy followed by local use of the insoluble sulphonamides. The results recorded here show that these modifications are of real value, and a large part of the book is about the practical application of the technique to various diseases of the colon and rectum. The authors describe the useful Devine operating frame; it is a great help in providing the extensive exposures necessary in this branch of surgery. Another device described is an ingenious pump for the direct transfusion of blood, a procedure now rarely used in Britain.

It is interesting to read that appendicostomy is revived as a treatment for some cases of ulcerative colitis when combined with the use of sulphonamides, although colectomy, partial or complete, by the new technique is performed for most cases. In the treatment of Hirschsprung's disease, too, the authors recommend total colectomy; the results of sympathectomy in these cases "afford little encouragement to continue its use." Not all surgeons would agree. Incidentally, we found the arguments about the experimental work on the autonomic control of the colon rather ambiguous in that the experiments showing that the lower bowel receives a motor (accelerator) supply from the parasympathetic are adduced as evidence against performing sympathectomy, whereas it would seem logically to be evidence in favour, at least if the conception of an antagonism of the two sides of the autonomic supply is accepted. The phraseology here and there sounds rather unusual to the English ear, and the occasional use of such words as "ectropionises" would raise a cry of despair from our purists. The book is well produced, of handy size, and copiously illustrated. We can highly recommend it.

NORMAN C. LAKE.

QUICK DIAGNOSIS OF TUMOURS

Identification of Tumors. Essential Gross and Microscopic Pathologic Features Systematically Arranged for Easier Identification. By N. Chandler Foot, M.D. (Pp. 397; 241 illustrations. 36s.) Philadelphia and London: J. B. Lippincott Company.

The motive behind this book is good; it is intended to be a vade-mecum for the microscopist, providing a quick diagnostic aid in much the same way as a botanist uses a pocket flora in the field. Without preambles about general theory, classifications, carcinogens, and so forth, the author goes straight to the description of types. Part I is on tumours of general distribution, Part II on those of special systems and organs. In each type described there are brief notes under side-headings in bold type indicating the source, site, clinical features, pathology, and differential diagnosis. The illustrative photomicrographs are abundant, but could be better interpreted if the stains used and the magnifications were stated. Technical notes and a tabulated arrangement of the tumours described are appended.

Attractively set out, this book would achieve its objective but for the presence of far too many statements to which exception may be taken. Thus (p. 208), the author gives the normal weight of a parathyroid as 3 g.; he states that carcinoma of the gall-bladder is extremely rare (p. 158); he lists the ileum (p. 144) as a site of adenocarcinoma, which is admitted to be less often so than the colon, but presumably not the excessively rare phenomenon which in fact it is generally considered to be. Apart from the malignant argentaffinoma, primary epithelial malignant tumours of the ileum are virtually unknown. Further instances of this kind could be added. There are also serious omissions. For instance, to take a few at random, the author does not mention the common *endochondromata* of the phalanges, whereas he gives pride of place to those of the articular cartilages—an unlikely site. In describing primary carcinoma of the liver (p. 154) he does not mention its common association with cirrhosis. He states that carcinoma of the bronchus (p. 111) metastasizes to the bones, suprarenals, spleen, and kidneys, but does not add the brain, liver, and pancreas, which are so commonly involved; nor does he mention on p. 129 the interesting sex differences in the distribution of carcinoma of the oesophagus.

The author's use of words, too, is often puzzling. Thus the term "metaplasia" appears both where one would expect it and also where most pathologists would say "anaplasia." It is to be feared that the student would find this book difficult to use in conjunction with the teaching of other textbooks.

DOROTHY S. RUSSELL.

SIGNS AND SYMPTOMS

Signs and Symptoms. Their Clinical Interpretation. Edited by Cyril Mitchell MacBryde, A.B., M.D., F.A.C.P. Second impression. (Pp. 439; 74 illustrations in black and white and 12 subjects in colour on 6 plates. £3 12s.) Philadelphia and London: J. B. Lippincott Company. 1948.

The recent development of laboratory and radiological methods of diagnosis has not diminished the need for expert clinicians. Useful though special tests are, they must be interpreted in relation to the patient's history and the findings on clinical examination, which remain as much as ever the keystone of medical practice. In MacBryde's own words: "... even to-day the accomplished physician can learn more in the majority of cases from what the patient says, and the way he says it, than from any other avenue of inquiry." In making a clinical assessment there are certain symptoms and signs which claim our attention because of their frequent occurrence and significance. This work is a collection of 26 articles, each on an important symptom or sign, from a team of distinguished contributors. It is excellent. By confining their attention to a few topics the authors have been able to discuss them fully, and there are few of us who could read this book without gaining a better understanding of phenomena that we encounter daily.

Where it strikes an original note is that the authors summarize the results of experimental work on their subjects and thus describe the processes concerned in the production of the particular symptom or sign. In other words, they have shown how clinical observations may yield information about the disturbed physiological processes of which symptoms and signs are the overt manifestations. Clinical medicine continues to advance not because we observe more exactly than older clinicians but because we are able to relate our observations to more precise scientific knowledge than was available to them, a circumstance well illustrated by this book.

Some of the articles are outstandingly good. That on headache by H. G. Wolff is largely derived from his own original studies and is admirable. MacBryde's article on dehydration presents in simple terms the modern conception of water and salt balance, and it is matched by an equally clear account of oedema by Wood and Sylvester. In his essay on "mouth and sore tongue" Vilter shows the refreshing effect of the new wine of scientific research into one of the old problems of clinical medicine. But all the articles are as good as the contents deserve, so this book yields a double pleasure.

PECKHAM HEALTH CENTRE

Health the Unknown. The Story of the Peckham Experiment. By John Comerford. (Pp. 144. 7s. 6d.) London: Hamish Hamilton.

This little book, in which the author describes the work of the Peckham Health Centre, is addressed to the layman, and it contains nothing that will be unfamiliar to medical men who have read Dr. Scott Williamson's books. It is a lively and well-written account which adds a small contribution to the considerable publicity which the Centre is now receiving. In one respect the book is unfortunately misleading. It represents the Centre as likely to be self-supporting, while the truth is that in the latest year's working the expenditure was £29,000 and the members' subscriptions provided but £3,500. It is apparent that the experiment cannot continue without Government support.

To many doctors, as to the reviewer, it has always seemed that the medical work of the Centre was much less important than its sociological activities. The main medical conclusion which emerges from the work at the Centre is that doctors, given time and improved facilities (especially adequate clinical pathology), can do better diagnostic work than is now attained in urban general practice. Moreover, some of its medical publications can be justly criticized. As a sociological experiment, however, it has already proved its value. It has demonstrated the biological importance of the family as a sociological unit; it has shown the need for group activities in the full development of the human being; most important of all, it has provided the only experimental station where mankind can pursue one aspect of his proper study—man in his environment. It would be a pity if this experiment were allowed first to languish and then to die.

D. V. HUBBLE.

PROBLEMS IN LIFE INSURANCE

Transactions of the Association of Life Insurance Medical Directors of America. Edited by Harry E. Ungerleider, M.D. Fifty-fifth Annual Meeting. Volume XXX (Pp. 378; illustrated. No price given.) New York City: Recording and Statistical Corporation, P.O. Box 594, Newark, N. Jersey.

This is a verbatim report of a meeting which took place in October, 1946. Various topics were discussed in relation to life insurance—rheumatic fever; electrocardiography (136 pages); thrombosis from the physiological viewpoint (Dr. C. H. Best); digestive ulcers, their significance and prognosis (Dr. B. B. Crohn); veterans as a medical underwriting problem; wartime experience with tropical diseases and their future significance; industrial medicine; chemotherapy; and finally an open forum which included a discussion on the insurability of the diabetic. The last 80 pages give membership details, cumulative indices, etc. Here is an extract illustrating the value of the text: "The life expectancy of the peptic ulcer case is impaired in comparison to the normal life expectancy of the control population by about 14%. In contrast to diabetes, to rheumatic heart disease, and similar chronic maladies the ulcer case offers a low rate of risk. The high incidence of ulcer in the general population (5–10%) creates for the actuary and for the medical director of life insurance companies a material problem. But the overall small risk to life offered by the ulcer applicant for insurance compensates for the magnitude of this number and brings assurance that the risk to life involved by the disease is in inverse proportion to the widespread distribution of the malady."

Physicians will appreciate Dr. Best's short and admirably clear account of the use of heparin and dicoumarol. They will also find the paper on rheumatic fever of considerable interest with its discussion on the significance of systolic and diastolic murmurs, and they will appreciate the account of chemotherapy, in particular the section on the use of streptomycin in urinary infections and infections of the typhoid group, although the figures given are now out of date. In the main this volume will interest the experts, medical and actuarial, at the headquarters of the various life insurance companies.

WILLIAM BROCKBANK.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

25^e Anniversaire de L'Institut d'Hygiène et de Médecine d'Outre Mer de L'Afrique du Nord 1923-1948. (Pp. 206. No price.) Algiers: Imprimerie Nord-Africaine. 1948.

Includes papers on syphilis and tuberculosis in Algeria.

Venins de Serpents et Antivenins. By P. Boquet. (Pp. 157. No price.) Paris: Flammarion. 1948.

A description of snake venoms and the toxic symptoms they cause, with an account of treatment.

Le Corps Médical et L'Assurance-Maladie. Syndicat des Médecins du Grand-Duché de Luxembourg. (Pp. 104. No price.) Luxembourg: Saint-Paul. 1948.

An account of health insurance in Luxembourg.

Über Neurome und Neuro-Fibromatose, nach Untersuchungen am Menschlichen Magendarmschlauch. By F. Feyrter. (Pp. 125. Sch. 35.) Vienna: Wilhelm Maudrich. 1948

A monograph of the pathology and symptomatology of neuroma and neurofibromas.

Malaria, Filariasis, and Yellow Fever in British Guiana. By G. Giglioli, M.D., M.R.C.P., D.T.M.&H. (Pp. 226. No price.) Mosquito Control Service, British Guiana. 1948.

A report on the control of these diseases by D.D.T.

Science News. Edited by J. L. Crammer (Pp. 160. 1s. 6d. London: Penguin Books. 1948.

Recent advances in science described for the layman.

The Biochemical Reactions of Chemical Warfare Agents. Edited by R. T. Williams. (Pp. 73. 5s.) Cambridge: University Press. 1948.

A symposium at which much experimental work done during the war was discussed.

Laboratory Technique in Biology and Medicine. By E. V. Cowdry. 2nd ed. (Pp. 269. 22s.) London: Baillière, Tindall, and Cox. 1948.

This edition includes new material, particularly on microchemical technique.

Heart. A Physiologic and Clinical Study of Cardiovascular Diseases. By A. A. Luisada, M.D. (Pp. 653. 55s.) London: Baillière, Tindall, and Cox. 1948.

An account of heart disease intended primarily for the general physician.

Remington's Practice of Pharmacy. By E. F. Cook, P.D., Ph.M. M.Sc., and E. W. Martin, Ph.C., B.Sc. 9th ed. (Pp. 1,511. 90s. London: Interscience Publishers. 1948.

A treatise on dispensing with description of medicinal substances their properties, uses, and doses.

Gynaecological Histology. By Josephine Barnes, M.A., D.M. M.R.C.P., F.R.C.S., M.R.C.O.G. (Pp. 242. 30s.) London: Harvey and Blythe. 1948.

A profusely illustrated guide to the histology of normal and abnormal tissues seen in gynaecological practice.

The National Health Service Act, 1946. By S. R. Speller LL.B. (Pp. 497. 42s.) London: H. K. Lewis. 1948.

The Act and a number of regulations are reprinted and annotated

A Textbook of Clinical Pathology. Edited by F. P. Parker M.D. 3rd ed. (Pp. 1,023. 50s.) London: Baillière, Tindall and Cox. 1948.

This is a largely revised edition of the textbook formerly edited by Dr. Roy Kracke.

The College Curriculum in Hospital Administration. (Pp. 107 52.) Chicago: Physicians' Record. 1948.

The final report by the American Joint Commission on Education

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 1 1949

ALLERGY, RHEUMATIC FEVER, AND
NEPHRITIS

Both rheumatic fever and nephritis belong to the group of diseases whose aetiology is still obscure. Most physicians believe that they are in some way related to bacterial infection, though Gordon¹ has recently suggested that a virus is the cause of rheumatic fever. The frequency with which a bacterial infection, usually a streptococcal sore throat, precedes a clinical attack of either of these diseases, and the fact that only rarely can organisms be isolated from the heart or kidney, have suggested that the lesions observed are the result not of direct bacterial injury but of an acquired hypersensitivity of the tissues to the products of the bacteria. The latent period that usually exists between the infection and subsequent renal or cardiac complication is compatible with such a view, since this would represent the time required for sensitization to take place. Two distinct immunological reactions have been suggested as causing the lesions in diseases attributed to allergy. In the first the injury is thought to arise as a result of interaction between antigen and specific antibody which has previously become fixed to the sensitized tissue. In this type of reaction, on which the various diagnostic skin tests such as the tuberculin test are based, no chemical relationship between the antigen and the sensitized tissue is postulated. The second type of reaction depends on the formation of specific anti-organ antibodies; injury results from the interaction between these and the organ concerned.

The first type of reaction has been most often used in experiments to produce cardiovascular lesions resembling those of rheumatic fever. The parenteral administration to rabbits of large quantities of horse serum has been shown by Rich and Gregory² to be often followed by lesions in the myocardium, endocardium, and valves very similar to those of rheumatic fever. The resemblance is remarkably close, even including the typical lesions seen in the coronary arteries and occasionally in the lungs. Arterial necroses characteristic of *periarteritis nodosa* also occur in these animals. As long ago as 1904 Aschoff³ described similar arterial necroses in cases of rheumatic fever. The experimental production of nephritic lesions by similar methods has not met with anything like the same success, and the disease was not convincingly reproduced until 1933. Masugi⁴ was then able to show that the second

type of reaction, hypothetical though it was, could be successfully applied to the production in experimental animals of an acute glomerulonephritis which closely resembled the human disease both clinically and pathologically. He produced a nephrotoxic serum in ducks by intraperitoneal injection of rabbit's kidney. Subsequent injection of the duck serum intravenously in rabbits caused acute nephritis. It must be admitted, however, that this experiment seems to bear little relationship to the mechanism by which nephritis is naturally produced in man. Since the antigenic stimulus exerted by any substance is closely related to its "foreignness," attempts to produce antibodies to organs from an animal of the same species almost invariably fail. If specific organ antibodies are really responsible for the lesions in nephritis and rheumatic fever then either some profound change must occur in the antibody-producing mechanism or in some way the animal's organ protein is rendered "foreign."

Cavelti⁵ has recently claimed that incubation of organ extracts with streptococci will so alter the antigenic nature of the former as to render them "foreign" to animals of the same species, with the consequence that when they are injected specific antibodies are formed. He also claims that the antibodies produced against these modified organ antigens will react with extracts of the unaltered organs. Thus incubation of rat kidney with streptococci so alters the renal protein as to render it antigenic when injected into other rats. Further, the antibodies so produced react specifically with extracts of normal rat kidneys, and such antisera given intravenously to normal rats are stated to have produced the clinical and pathological signs of glomerulonephritis. Cavelti also carried out a similar experiment in which heart extracts replaced the kidney extracts; the lesion resulting from the parenteral administration of this antiserum resembled acute rheumatic carditis. On the basis of these experiments Cavelti has suggested that the streptococcal infection that usually precedes acute rheumatic fever or acute nephritis results in an interaction *in vivo* between streptococcal products and organ antigens; that during the quiescent phase antibodies are being produced against these modified organ antigens; and that when these reach an appropriate level the interaction between these antibodies and the organ in question results in disease. In substantiation of this theory he maintains⁷ that 12-48 hours after focal streptococcal infection in rats organ antigens of heart and kidney are demonstrable in the circulating blood and that 7-12 days later antibodies to these antigens can be detected. In none of these animals, however, were lesions subsequently found in the heart or kidneys.

That the two types of allergic mechanism here discussed are fundamentally similar is suggested by the work of Kay.⁸ He noted, in repeating Masugi's work, that an interval of approximately seven days occurred between the injection of the nephrotoxic duck serum and the appearance of nephritis in the rabbits. He therefore suggested that during this interval the rabbit was producing antibodies to the

¹ *Lancet*, 1948, 1, 697.² *Bull. Johns Hopk. Hosp.*, 1943, 73, 239.³ *Verh. dtsch. path. Gesellsch.*, 1904, 8, 46.⁴ *Beltr. path. Anat.*, 1933, 91, 82.⁵ *Arch. Pathol.*, 1945, 39, 148, and 40, 158 and 163.⁶ *Ibid.*, 1947, 44, 1.⁷ *Arch. Pathol.*, 1947, 44, 119.⁸ *J. exp. Med.*, 1940, 72, 559.⁹ *Ann. rheum. Dis.*, 1948, 7, 97.¹⁰ *Helv. med. Acta*, 1945, 12, 547.¹¹ *Ibid.*, 1946, series A, 13, 456.¹² *Schweiz. med. Wschr.*, 1947, 77, 1069.

duck globulins which include the anti-kidney antibodies, and that renal lesions developed when the rabbit antibodies reacted with the duck globulins which became fixed in the rabbit's kidneys. In other words, in both types of mechanism the lesion is caused by the union of antibody with antigen in or on tissue cells, the site of reaction depending upon the site of fixation of antibody or antigen. In most experiments of this kind antibody is usually localized in the cardiovascular system, and the subsequent lesions are therefore cardiovascular. The experiments of Masugi and Cavelti indicate two methods by which antibody may be localized in other sites. There is obviously scope for further work on the factors determining localization and hence the site of interaction of antigen and antibody.

If it be accepted that rheumatic fever and nephritis occur as a result of allergic hypersensitivity, then the next step in the investigation of these diseases should be the identification of the antigens responsible. In the case of rheumatic fever the evidence is strongly suggestive that the antigen is a part or product of haemolytic streptococci. The relationship of acute nephritis to streptococcal infections is almost as close. The difference in the two diseases must therefore reside either in the particular streptococcal fraction constituting the antigen or in other factors that determine differences of localization of antibody. Wallis⁹ similarly suggests that the differences between rheumatoid arthritis and acute rheumatic fever are fundamentally due to differences in the reacting antigen. Much remains to be learned about how the reaction between antigen and antibody injures the tissue in which the reaction occurs. That histamine is amongst the products liberated and responsible for some of the characteristic pathological manifestations of these reactions is now well established. It is therefore of great interest to the pathologist and the clinician that the antihistamine drugs have been used with some success in both nephritis and post-streptococcal carditis. Reubi¹⁰ and Steinmann and Reubi¹¹ found these drugs of value in experimental and in human nephritis, and Steinmann¹² has recently reported good results with "antistin" in cases of the delayed form of myocarditis that may follow scarlet fever. Elsewhere in this *Journal* we publish a paper by Professor John Craig and Drs. N. S. Clark and J. D. Chalmers which is the first report of the use in this country of antihistamine drugs in the treatment of acute nephritis. As the authors admit, the number of cases and controls is far too small for definite conclusions to be drawn, but the difference in response as judged by duration of clinical signs is so striking that the authors are certainly justified in appealing for a wider clinical trial of this form of treatment. Moreover, since one of the greatest dangers in acute nephritis is the residue of permanent renal damage, any treatment that significantly reduces the duration of the acute phase merits serious consideration. Since it is extremely unlikely that the lesions of the heart or kidney that result from allergic hypersensitivity are entirely due to local histamine production, favourable reports such as these were unexpected. If the results be confirmed they will provide strong support for the theory that nephritis and rheumatic fever are allergic conditions.

INTERNATIONAL SANITARY CONVENTIONS

From time to time in this *Journal* it has been pointed out that the various international conventions which are supposed to restrict the spread of infectious disease from one country to another and thus to safeguard international health are far from effective. The first International Sanitary Convention, it may be recalled, was signed in 1903 with the object more especially of restricting the spread of cholera, which in the nineteenth century had become a menace to the whole world. The 1903 Convention was succeeded by that of 1912 and that of 1926, which was modified in its turn in 1938. Cognizance was taken of yellow fever in 1912 and of plague and typhus in 1926. The rapid development of aviation led to the International Convention for the Sanitary Control of Aircraft in 1933. During the war many of the provisions of this convention were unworked and were seen to be obviously unworkable; it was therefore modified in 1944, as was also the Sanitary Convention of 1926-38. The man in the street might therefore well imagine that the frequent modifications and adaptations undergone by the conventions had permitted the establishment of a complete system of international sanitary control confirmed by experience and based on effective rules to which all the countries of the world have adhered. Unfortunately this would be altogether too optimistic a view.

In a recent analysis of the present situation Gaud¹ has brought to light the following interesting but alarming facts. There are some 70 sovereign States in the world on whose co-operation the workings of international sanitary conventions depend. So far as maritime navigation is concerned 9 countries are bound by the Conventions of 1912, 1926, and 1944; 5 by the Conventions of 1926 and 1944; 1 by the Convention of 1944; 14 countries are bound only by the Conventions of 1912 and 1926; 9 only by the Convention of 1926; 10 only by the Convention of 1912; and 16 countries are bound by no convention whatsoever. So far as aerial navigation is concerned 9 countries are bound by the Conventions of 1933 and 1944; 9 by the Convention of 1944; 16 by the Convention of 1933; and 36 by no convention.

Apart from the fact that these sanitary conventions do not approach that principle of universality without which their efficiency is sadly lacking, this curious state of affairs has other effects. Since many countries are bound by no particular convention they are free to take the law into their own hands. Some countries refuse to trouble themselves and take few if any precautions; others, as was seen during the cholera epidemic in Egypt, have rushed to the other extreme and imposed restrictions which go far in excess of what is required. There are in fact not many countries in which national sanitary laws and regulations do not run counter in some way to international conventions and accords. Many aeronautical companies faced with differing regulations in different countries have insisted that their passengers should be inoculated against every conceivable disease. The unfortunate wife of an officer and her three children, for instance, who wished to fly from Paris

¹ *Ser. II* *Paris*, 1948, 24, 201.

² Findlay, G. M., *British Medical Journal*, 1946, 2, 979.

to China were forced to submit to inoculation against smallpox, yellow fever, cholera, plague, typhoid, and paratyphoid. In these circumstances it is hardly surprising that Gaud confirms what was stated in this *Journal* two years ago—namely, that international health certificates are being forged and can be bought on the black market.

It is obvious that one of the major tasks of WHO, and one which is of considerable urgency, is to draw up a new single convention to which all countries will freely subscribe. There are at present 17 separate conventions or accords, without counting the texts of the documents constituting WHO signed in New York in 1946. Such a unitary convention must not be cluttered with the dead wood of previous conventions, the provisions of which were too often drafted not by experts but by persons who, though they may have had medical qualifications, had spent many years in government offices. As a result the conventions may have been impeccable on the diplomatic level but were often sadly ineffective on the practical level. The Assembly of WHO, according to Article 19 of the Charter, has authority to adopt conventions and accords relating to every question within the competence of the organization. A majority of two-thirds of the Assembly is necessary for the adoption of these conventions and accords, which will come into force so far as each member State is concerned as soon as the particular State has accepted it, in conformity with its constitutional rules. A permanent technical organization has thus taken the place of the old cumbersome diplomatic machinery which had to be invoked whenever a new convention had been drafted. It is sincerely to be hoped that there will be not only a change of form but of spirit, and that governments will be less slow and less indifferent to accepting conventions or regulations fully discussed and already adopted by the Assembly of WHO.

The WHO Expert Committee on International Epidemiology and Quarantine is already alive to the present difficulties, and their ultimate aim is to combine the revised international conventions into uniform WHO regulations which after adoption by the World Health Assembly will come into force automatically without the need for further ratification on the part of national legislative bodies. A number of broad principles to serve as a basis for drafting WHO regulations have already been laid down, and these are to be submitted in June, 1949, to the Second World Health Assembly. They are aimed at establishing international standards on such varied matters as the sanitation of airports, disinsection of aircraft, and quarantine measures applicable to migrants. Beginning in January, 1949, WHO is also going to broadcast daily epidemiological data from Geneva to all parts of the world. This will allow governments to take precautionary measures more rapidly and, it is hoped, more effectively.

MASTER MINDS

Mr. Fred Messer, Labour M.P. for Tottenham, holds the responsible position of chairman of the Central Health Services Council. He is also chairman of the North-West Metropolitan Regional Hospital Board. He has earned these positions of trust on his reputation as a highly able administrator with a special interest in and knowledge of

hospital and medical services. But according to a recent report in the *Hendon Times* it would appear that Mr. Messer allowed himself to adopt a highly partisan attitude to medical men and the work they do. This was at a meeting of the North-West Branch of the Socialist Medical Association under the chairmanship of Dr. S. Leff, medical officer of health for Willesden. Mr. Messer is reported to have said this: "In the days before the new Act, the people were only allowed to be ill at certain times during the day—the times set down on the brass plate in front of the doctor's doors." What kind of confidence can the medical profession have in the chairman of the Central Health Services Council if he makes such ill-judged, inaccurate, and unjust remarks—remarks directed at men and women who after a hard day's work have to be ready to get up at any time of the night in response to a call for help? "For too long," Mr. Messer goes on, "the needs of the people have been subservient to the needs and training of the doctors." What nonsense this is! Mr. Messer again goes on: "Now for the first time the health service as a whole will have a master mind behind it." Does he mean the mind of the chairman of the Central Health Services Council, or the uncoordinated mind of an endless series of Ministers of Health? The medical profession itself has always been in advance of the Government in pressing for improved organization and integration in medical services, and does not underrate the value of the administrator or deny the need for administration so long as it is made subservient to the need of the doctor to give to his patients in the most efficient manner the knowledge and experience wrung from stubborn nature by the master minds of medicine. Our new administrators have yet to learn the lesson of humility, the humility of the man who minds the machine created by men who understand how it works.

BRUISING OF THE HEART

It is now generally recognized that trauma to the praecordium, particularly a severe blow or crushing injury, may occasionally damage the heart even where there is no obvious injury to the chest wall or fracture of the ribs. The symptoms and signs vary considerably, but there may be immediate severe pain lasting minutes or hours, angina pectoris and effort dyspnoea persisting for days or weeks, the development of pericarditis during the following week, and electrocardiographic changes. Most of the latter are evanescent, and unless the patient is examined within a few days of the accident no abnormality may be found. Partial heart block may occur, and this tends to persist for much longer than the other changes. Experimental work and necropsy studies suggest that the usual lesion in the heart is a contusion with varying degrees of oedema and extravasation of blood, or perhaps a tear in the myocardium, though this is less common. Further, for some reason which is not clear, the right auricle appears to be particularly vulnerable. However, the majority of these patients, provided they are not otherwise severely injured, usually recover, and the precise anatomical lesion remains a matter for speculation. Elsewhere in this issue Drs. G. Parsons-Smith and Denis Williams report the case of a boy with a fairly clear-cut picture of a cardiac contusion, with pain, pericarditis, and partial heart block; the damage was done during a boxing match. Two days after the injury he developed a hemiplegia which appeared to be embolic in origin. This clearly suggests that the cardiac injury had spread through the heart to the endocardium and resulted in an embolus, part of which became detached, and the explanation is...

injury may be. In this case the history indicated that a previous, but less severe, cardiac injury had been caused in a similar manner twelve months before.

INDUSTRIAL WASTES

A plentiful and pure water supply has become part of the environment of most of the inhabitants of this country, and it is apt to be forgotten that such a supply is not a natural phenomenon under most conditions of modern civilization. Our rivers and other sources of water are often grossly polluted by excretal and other wastes and by trade effluents. Those responsible for the purification of water supplies by modern methods must continually exercise great skill and care. In his book¹ on the disposal of industrial waste waters Dr. B. A. Southgate, who is director of water pollution research at the Department of Scientific and Industrial Research, has described the problems involved and the researches which have been and are being made in the attempt to solve those problems.

Most industrial wastes contain in solution or in suspension materials of organic or inorganic nature which are oxidizable and will therefore absorb from the diluting stream the oxygen which is in solution. If effluents which have this action are allowed to enter a stream and to reduce the amount of oxygen in the water below a certain level, fish will die from lack of oxygen and the normal flora will gradually disappear. Solids will be deposited on the bed and banks of the stream, the final result being a complete destruction of its natural characters. Domestic wastes have the same polluting effects, which, however, can be sufficiently reduced in a good sewage works by processes which are mainly biological. Industrial wastes are in general much more polluting than domestic wastes and may have the further disadvantage of containing substances directly toxic to fish or lethal to the bacteria on which successful purification of domestic sewage depends. Some trade effluents may give the stream into which they flow an unpleasant taste or colour, and this stream may later be used as the source of a water supply. Although a certain amount of crude industrial waste can be allowed to enter the diluting streams or the sewage plant, it is usually desirable and often essential that trade wastes should be treated before they are voided from the works.

Industrial effluents differ widely, and each type has to be investigated separately and the manufacturing processes studied at every stage. Dr. Southgate explains the processes used in a large number of industries and the scientific principles involved in the methods which have been adopted to purify the wastes, and he describes the results obtained. There are industries in which the wastes contain much organic matter, as in the textile industries, laundries, leather manufacture, slaughter-houses, dairies and milk products factories, the canning and drying of food, and the manufacture of malt, beer, and alcohol. On the other hand, the carbonization of coal, the pickling of steel and copper, and the use of chromates and cyanides in manufacturing processes produce chemical wastes. The treatment of the effluent in each case by physical, chemical, or biological means presents different problems, and there is the further difficulty of avoiding undue waste of valuable materials. It is sometimes possible to economize in water by the re-use of washing water. From organic waste it may be profitable to recover valuable materials such as fats, or by bacterial digestion to obtain gases of use for power purposes. Even the indigestible residue may be useful as manure. Valuable materials may be recovered from

chemical effluents also, as in the extraction of copper by crystallization or deposition on iron.

Much remains to be done not only in applying what is known but also in further research. Our rivers are unable to cope with the pollutions they receive, but there is great hope of improvement now that industry is paying more attention to the treatment of wastes; the operation of the Public Health (Drainage of Trade Premises) Act, 1937, should also have good results. Nevertheless, the problem of maintaining the purity of surface and underground waters in a densely populated and highly industrialized country is Herculean and may perhaps never be completely solved.

TREATMENT OF PERTUSSIS

During 1947 the number of deaths from pertussis in Glasgow exceeded the combined total of deaths from scarlet fever, measles, diphtheria, and cerebrospinal fever.¹ All the common fevers now cause fewer deaths than 20 years ago, but in pertussis the rate of reduction has lagged far behind. As yet chemotherapy has not supplied the remedy: the sulphonamides seem much less effective than, for example, in measles. Swift's² preliminary report on the interesting new antibiotic polymyxin is encouraging, but more extended trials are necessary. Workers in the U.S.A. have now had considerable experience with different forms of immune sera, and Felton,³ who reviewed the subject in 1945, considered that a case had been made out for their use. Both human and rabbit sera have been tried. The former, from hyperimmunized adults, may be used as lyophilized serum or as the concentrated globulin fraction, and the latter is also available as concentrated globulin. Some workers have felt that the serum should be both antibacterial and antitoxic, and Beaudet⁴ used such a rabbit serum in a series of 50 children, with successful results. McGuinness and his colleagues⁵ gave injections of a lyophilized human serum to 442 patients, of whom 176 were under 6 months of age, and classified 70% of the results as excellent. More recently Kohn and his co-workers⁶ have reported on the use of three forms of serum—two human and one rabbit. They regarded the response as satisfactory in 80% of those under 1 year, but the results were less good in patients over that age.

The same criticism can be made about many of these therapeutic trials—namely, that the treatment of a control series has often not been undertaken. The fact that pertussis has diminished in severity during recent years makes it undesirable to compare present results with those obtained in a previous period. There is indeed no sure method of foretelling the outcome in this fickle disease, but to give improved forms of treatment a fair chance earlier diagnosis is essential. It is tragically true that the majority of cases are diagnosed so late in the disease that any form of treatment is likely to be ineffective. In Kohn's series only 2% were admitted before the onset of whooping; a further 77% were seen during the first week of the whoop, when they were already in the late second or third week of illness. Cruickshank⁷ drew attention to the value of the post-nasal swab, which he inoculated on Bordet-Gengou medium containing penicillin, but many workers have found that swabbing the post-nasal space through the mouth is almost as cumbersome a method as the cough-plate, which was not designed for the general practitioner.

⁹ Proc. Soc. exp. Biol., N.Y., 1940, 43, 590

But more recently Cockburn⁸ has shown that when the pharyngeal swab is taken through the nose, as advocated by Bradford and Slavin,⁹ not only is the method more simple for the clinician but the results from the bacteriologist's point of view are much more satisfactory. If earlier diagnosis were to be made possible by the use of such a method, patients could be more promptly isolated. Early isolation, quite apart from limiting the spread of the disease, should reduce the risk of secondary bacterial infection and possibly of bronchopneumonia, and treatment with serum or chemotherapeutic substances is more likely to be effective if started before the disease has become well established.

HOUSE WARMING

A long-term experiment in domestic heating which is being carried out at the Building Research Station under the auspices of the Department of Scientific and Industrial Research was described at a recent meeting at the Royal Institute of British Architects. The research is aimed at finding out how houses can be heated with the most economical consumption of fuel and in the most effective manner for all domestic purposes. Eight small semi-detached houses at Abbot's Langley, Hertfordshire, all built to the same design but with different degrees of thermal insulation, have been equipped with identical heating systems in the endeavour to find out how much heat is conserved by improvements in insulation. In a parallel experiment twenty similar houses have been built with identical insulation but equipped with many different heating systems and appliances, including gas and electric convectors, gas and electric-storage heaters, electric tubular heaters, and multipoint gas water-heaters. The apparatus in each of the houses is closely superintended by the research station staff, with the willing, though largely passive, co-operation of the tenants. The experiment started in September, 1947, and is expected to last for some years.

The interim results made known up to the present are so highly detailed and carry so many qualifications that it would be difficult, if not impossible, to draw any broad conclusions applicable to British housing as a whole. The economics of house heating have been taken as the first point of attack. It has been found possible economically to maintain in a house of 900-1,000 sq. ft. (83.5-93 sq. m.) floor space a constant minimum temperature over the whole house of 30° F. (18° C.) above the outside temperature by means of central heating and anthracite-burning boilers, the efficiency of which is highly praised. Systems of whole-house heating are more expensive to install but much more economical in fuel. As for insulation, one contribution which architects can make to fuel economy and domestic comfort is to put the flues well inside the insulated envelope and not throw away the valuable heat which the flues contain, particularly for houses of two or more stories, by enclosing them in outside walls. It was generally agreed by the architects present at the meeting that the need for better heat insulation in house construction must be taken into account in all future building. Here again the additional cost, whatever it may be—and it cannot represent much on the total value of the house—is well worth while not only for the saving of fuel but also for the health of the occupants. The method of ventilation followed in the experiment, using outlets from bedrooms into the roof, was commended in preference to the "by-law" type of grating, which is often stuffed up with brown paper to keep out draughts. One architect pointed out that whole-house heating would enable a more open plan of house construc-

tion to be carried out, and many of the small halls and passages and tiny rooms, partly arranged in order to seal off the cold areas of a house, could be eliminated. Whole-house heating systems have been in use for a long time in other countries, and some complaint was made of the lack of enterprise of British manufacturers of heating appliances.

There may well be prejudices, traditional views, and perhaps more practical objections to be overcome before whole-house heating commends itself to householders in Britain. Most of us prefer an obvious source of radiant heat, represented by the open coal fire, though admittedly this is wasteful of fuel and also fails to warm the room equably. Families accustomed to gathering round the hearth will not easily be reconciled to the absence of a fireplace even though every corner of the room is properly warmed. Again, quite a large number of people have a firm belief in the virtues of a cold bedroom. Certainly any revolutionary changes in the warming of houses which might result from the Building Research Station's experiment should be accompanied by a careful check on the health of the people who live in the constant-temperature houses as compared with those who hold to the traditional half-cosy, half-Spartan routine. Centrally heated houses in North America are usually too warm to be comfortable for the British visitor, but the residents there are said to suffer just as much from colds and rheumatic disorders as do people in this country. In America, also, the atmosphere inside houses is often so dry that it has to be humidified for the comfort of the residents. The Building Research Station's experiment, which is said to be the only one of its kind ever undertaken in the world, will be well worth while if it succeeds in solving some of these important problems.

ARSENICAL TOXICITY

Since 1939, when wider use began to be made of rapid methods of treating syphilis with arsenic, the incidence of cerebral reactions in North America appears to have been about 1%.¹ These reactions are given the name of arsenical encephalopathy; in fatal cases brain haemorrhages occur. Sexton and Gowdey² became interested in the similarity between the pathology and symptoms of arsenical encephalopathy and those of acute deficiency of vitamin B₁, and in a comparison of the two conditions they observed that a patient receiving a 5-day intravenous drip who developed peripheral neuritis recovered remarkably quickly after receiving massive doses of the vitamin. They attempted to follow the changes in the blood concentration of vitamin B₁ in patients receiving the 5-day treatment with "mapharside" by determining the ratio of lactic acid to pyruvic acid in the blood. In vitamin B₁ deficiency the amount of pyruvic acid rises above the normal. In 9 out of 13 patients treated with mapharside by the 5-day intravenous drip method the level of pyruvic acid rose early and remained above normal until the treatment was finished. The blood sugar rose also, and the hyperglycaemia persisted during the treatment. Clinically there was an increase in sensitiveness of arm and leg muscles to pressure. When these signs and symptoms had developed, the intravenous injection of 600 mg. of vitamin B₁ caused a fall in the sensitiveness of the muscles to pressure. The evidence presented by the authors cannot be considered complete, but their results clearly suggest that not only BAL but also vitamin B₁ is of value in the treatment of the lesions of the nervous system caused by arsenical poisoning.

MEDICAL FOUNDATION OF EPSOM COLLEGE

The Royal Medical Foundation of Epsom College appeals to all members of the medical profession who do not already do so to subscribe to the Foundation, the object of which is to help the families of less fortunate colleagues. The Foundation in 1948 has provided more than £18,000, as follows:

50 ordinary pensions to medical men or their widows ..	£ 1,500
45 Foundation scholarships for boys (educated, clothed, and maintained entirely free of cost) ..	8,702
13 scholarships for girls ..	570
Education of 28 boys at reduced fees ..	1,968
140 pensions and annuities of varying amounts ..	3,023
Grants towards education of 56 boys and girls ..	1,843
Grants to medical men, widows, and spinsters ..	497

In order to maintain this assistance the Foundation has to rely upon the generosity of subscribers and donors for over £14,500 a year. Without sufficient help from them the existing benefactions would have to be curtailed. Owing to lack of funds, many deserving applicants—medical men, widows, and children of school age—remain unassisted. The Sherman Bigg Fund enables the Foundation to make educational grants for those who cannot obtain scholarships. Donations to augment the income of this Fund will be most welcome. Subscriptions and donations for whatever aspect of the work may be sent to the Secretary, Epsom College, Surrey.

CHILD DEVELOPMENT STUDY

It has long been felt by those concerned either with the health or with the education of children that a close study of growth and development, both physical and psychological, conducted on the same group of children in a parallel series of observations would yield valuable results. In 1947 Dr. D. H. Geffen, medical officer of health of St. Pancras, and Professor Alan Moncrieff, of the Institute of Child Health, placed before the Governors of the Foundling Hospital in London a scheme for utilizing their excellent facilities at Coram Gardens—residential nursery, day nursery, and nursery school—for teaching and research purposes. This was sympathetically received, and a further suggestion that a maternity and child-welfare centre might also be started on the same site by the reconstruction of a derelict building was favourably considered by the authorities concerned.

The next development arose when the Central Council for Training in Child Care, which is concerned with the training of boarding-out officers and house mothers under the Children Act, found a shortage of seniors who could take up posts of a supervisory character or as tutors in the various education schemes. The Institute of Education of the University of London and the Institute of Child Health therefore decided to put forward a plan for a joint training and research centre at the Foundling Hospital site. This was discussed with representatives of the Home Office, of the Ministry of Health, and of the L.C.C. Public Health and Education Departments. The two Institutes consulted their own Academic Boards and governing bodies and a final scheme was decided upon, the financing of the teaching side being undertaken by the Institute of Education and that of the research side being shared between this Institute and the Institute of Child Health, with the approval of the appropriate University of London Committees and eventually of the Senate and Court.

A joint committee for the two bodies has been meeting to make detailed plans. On the training side the first course will begin in January. Provision has been made for the appointment of a senior tutor and a junior tutor and for visiting lecturers. Dr. Agatha Bowley has been appointed as senior lecturer in child care and Miss J. E. Cass as tutor in child care. Members of the teaching staff of both Institutes will take part in the course. Miss Cass has also been appointed as honorary educational supervisor to the day nursery on the site so that there may be some general co-operation with staff in relation to the training of probationers for the day Nursery Certificate. On the research side provision has been made for two educational research assistants, for a

part-time medical assistant, and for part-time assistance from the Child Guidance Clinic at the Hospital for Sick Children, Great Ormond Street. Plans for a pilot survey are well advanced. In addition to detailed observations on children in the nurseries and nursery schools it is planned to extend the investigation to babies in the same area who are not attending such institutions. One of the objects of the research programme is to attempt to assess in this way the educational values or disadvantages of the nursery or nursery school. Those concerned with the planning are endeavouring to take a long view, hoping to follow children through the nursery school to the primary school period, and even eventually to adolescence in the youth centre activities in the Harmsworth Memorial Playground, also on the site of the original Foundling Hospital.

Reports of Societies

HEPARIN AND DICOUMAROL

At a meeting of the Medical Society of London on Dec. 13, 1948, with Dr. JENNER HOSKIN presiding, the subject discussed was the therapeutic action of anticoagulants.

Dr. PAUL WOOD described the effects of heparin and dicoumarol in about 100 cases. Heparin was discovered over thirty years ago, but it was twenty years before it was purified for therapeutic use. The dose of heparin was 50 mg. four-hourly for a fairly short time. It could be given by drip, 3 pints (1.7 l.) in 24 hours, each pint (0.57 l.) containing about 100 mg. If that dose were given, they could be sure that the clotting time would not be less than 10 seconds. Dicoumarol was a relatively new drug in this country. The dose given was usually 300 mg. by mouth on the first day, 200 mg. on the second day, and 100 mg. on the third. It had no action for 48 or perhaps 72 hours. Later the doses were determined by the effect on the prothrombin time. The reaction of patients differed considerably from the entirely resistant to the extremely sensitive. Dicoumarol could be dangerous; an overdose resulted in severe haemorrhage, which was very difficult to control. In his own experience and that of his colleagues vitamin K had no effect at all. It was very important to have the prothrombin measured every day or every second day and to keep to round about 30 to 40 mg. per 100 ml. He proceeded to give a few of the results obtained at his hospital during the last two years. Cases of pulmonary embolism numbered 20, 5 of them massive. The average duration of treatment was 26 days, and there were 5 deaths. Cases of cardiac infarct numbered 23, the average duration of treatment was 27 days, and there were 3 deaths; 7 cases of cardiac embolism complicated by pulmonary embolism were treated for 27 days, with 3 deaths. There were 3 cases of arterial occlusion treated for 14 days, with no deaths.

Dr. Wood went on to discuss 10 cases of angina at rest treated on the average for 29 days. No deaths occurred until after the end of treatment; there were two deaths later. The object of the treatment was to prevent coronary thrombosis, and it was extremely difficult to decide whether or not coronary thrombosis would have taken place under a different regime. The decision depended upon the adequacy of the controls, which were not easy to obtain. Contrasted with nine controls treated in a different way, the advantage appeared to lie with the heparin and dicoumarol treatment. The sedimentation rate was very helpful in finding out whether infarction had taken place or not. Dicoumarol in therapeutic doses did not raise the sedimentation rate. One case was that of a doctor who two weeks previously had suffered severe pain in the chest while walking. Later it affected him while he was in bed at night, and shortly afterwards he got the pain on the slightest exertion. The electrocardiograph was normal. He was put on heparin and dicoumarol for seven or eight weeks. This patient was thought to have an active pulmonary embolism, but that was shown not to be the case. He had a good recovery and was now well. In another case substernal pain had persisted for two months, and treatment was followed by complete recovery. The majority of these cases were seen in private practice; they were not commonly seen in hospital until after infarction.

Of the two late deaths in this small group of ten cases of angina at rest, one occurred suddenly about a month after the treatment had stopped, and the other patient died of ventricular fibrillation two or three weeks after the cessation of treatment. The rest recovered without infarction and he offered the results for what they were worth.

Heparin in Arterial Surgery

Mr DICKSON WRIGHT said that haemorrhage was such a dramatic and dangerous event that methods for its control were always being evolved, but intravascular clotting had not received the same attention, and until recent years it was regarded as an unavoidable disease for which rest and patience were the only treatment. It was now realized that many more patients died of clotting accidents than of haemorrhage. At present there were only the two anticoagulants available, and administration was complicated so that they could only be used in the prevention of impending thrombosis or in the treatment of established thrombosis. Even in this field there was hesitancy about using them, the 20% death rate from embolism being risked rather than the negligible, but dramatic deaths from overdosage and haemorrhage. It was often feared that heparin would soften the clot and increase the risk of embolism, but this was not the case.

The great value of heparin lay in the treatment of thrombosis of the lower extremities starting spontaneously or post partum or post-operatively. It had been proved conclusively that once heparin was administered the clot did not grow 1 cm further, the clots in the lung and the local recent clot disintegrated and danger was practically over. The earlier the disease was diagnosed and therapy instituted the less danger did the patient run and the less permanent damage was done to the limbs. Prophylactically heparin could be used in cases in which there had been thrombosis with previous pregnancies or operations. It was given from 48 hours after the delivery, or operation until the patient was out of bed. The dosage of heparin must be adequate. It consisted of four daily intravenous doses at 8 a.m., 12 noon, 4 p.m., and 10 p.m. The first and last doses were 12,500 units and the intermediate ones 10,000, each 100 units was 1 mg of heparin.

Mr Dickson Wright went on to describe the use of heparin in arterial surgery of the limbs, lower aorta, and iliac arteries. The value of heparin in these cases lay in the prevention of clots which tended to form at the suture lines of anastomosis and embolectomy incisions producing a secondary obstruction from arterial thrombosis. In these cases the clotting time was important and should be left carefully at 30 minutes. Blood transfusions could be given with heparin as an anticoagulant (2,000 units to each litre), and for the recently suggested method of bleeding the patient at the start of the operation and the return of the blood at the end it was the ideal substance. He instanced many other uses of heparin—in venesection in cases of polycythaemia, in inducing skin grafts to adhere with plasma glue, in the prevention of portal and other forms of thrombosis after splenectomy, in the treatment of gangrene, etc.

Dicoumarol had the advantages that it did not require intravenous injection and it was cheaper than heparin. It was a selective liver poison. Its antidote was a blood transfusion and vitamin K. To control its use there must be an estimation of the prothrombin reduction in the blood. The disadvantages of the drug were its two-day delay before it took effect—a gap which could be covered by heparin—and the cumulative action. The Mayo Clinic method of administration of dicoumarol was a single daily dose of 300 mg on the first day and on every day after this when the prothrombin was greater than 20 mg per 100 ml. When less than 20 mg per 100 ml no dicoumarol was given. If the figure fell below 10 units menadione bisulphate 30 mg was given intravenously, and when dicoumarol was resumed with the prothrombin content rising above 20 units 100-mg doses were used. Haemorrhage was countered by a fresh transfusion of citrated blood and 60 mg of menadione bisulphate.

Mr Dickson Wright said that when prothrombin estimations were hard to come by he himself recommended 300 mg on the first day, 200 on the second and third day, 200 on the tenth, eleventh, and twelfth day, 200 on the twentieth day, and 100 on the twenty-first and twenty-second day. He felt that the value of the drug, even without estimations, much more than compensated for the dangers of overdosage. The drug was specially

dangerous when used in long-continued small daily doses or in cases wrongly diagnosed as thrombosis.

The main indications for the drug were (1) in treatment of thrombosis in varicose veins, combined with "elastoplast" support, (2) in the prophylactic and curative treatment of deep thrombosis spontaneous or post partum or post operative, (3) in prolonged forms of thrombosis such as thrombophilia, gouty thrombosis, and thrombophlebitis migrans where the patient remained prone to thrombosis for many months. Thrombophilic sufferers were wise to travel with a stock of heparin and dicoumarol and to know their responses to these drugs.

The President said that he had been particularly interested in Dr Paul Wood's description of the cases of angina at rest. He had always been afraid for the patient who came up with a very short history of angina (two or three weeks). The likelihood of the development of coronary thrombosis seemed to be much greater in his case. What one would have liked would have been a drug available after coronary thrombosis had occurred but so far as could be seen—some work had been published in America this year on experiments on dogs after ligating one of the coronary vessels—the results of using dicoumarol had been entirely disappointing.

Notwithstanding a crowded meeting no one rose to sustain the discussion, and the meeting terminated.

CLINICAL APPROACH TO NEUROLOGY

At a meeting of the Devon and Exeter Medico-Chirurgical Society on Dec 16 1948, Dr F M R WALSH spoke on the clinical approach to neurology, defining "clinical" as the method of direct study of the patient at the bedside by means of the five senses. The various techniques elaborated within recent years for neurological investigation said Dr Walshe, were tending to become substitutes for clinical investigation. He discussed the scope and limitations of lumbar puncture in certain nervous diseases. By the time cases of suspected intracranial tumour reached the specialist nowadays lumbar puncture had generally been done. In such cases this was a useless and irrational procedure not without hazard. Again, purely clinical investigation was usually all that was necessary to diagnose disseminated sclerosis. Nevertheless, lumbar puncture, which might exacerbate symptoms in this malady, was often undertaken as a routine instead of as a last resort for the specific purpose of differential diagnosis in exceptionally difficult cases. Dr Walshe wondered why lumbar puncture was so often done in cases of multiple neuritis. In acute anterior poliomyelitis it was sometimes justifiable—for example, to confirm the diagnosis or to exclude meningitis in a suspected case in a residential school—provided that the pathologists' report on the fluid withdrawn was speedily forthcoming. It was not justifiable to perform lumbar puncture on a screaming and struggling child in the pre-paralytic stage, indeed it might tip the scale in favour of paresis and against complete recovery if performed at a time when it was essential to keep the child still.

Turning to epilepsy Dr Walshe said that electro-encephalography was rapidly becoming a routine diagnostic procedure, though it was by no means infallible. Clinical judgement was still the most effective weapon for diagnosing this disease. The diagnosis of expanding or space occupying lesions of the skull could in some cases be achieved only by ventriculography, but many cases could be diagnosed without it. Neurosurgeons were apt to be too "tumour conscious" and it was not always easy to decide when a ventriculogram should be done or whether it should be done at all. Of all cerebral tumours nearly half were gliomata which could not be extirpated without inflicting severe physical and psychic trauma. In slow-growing tumours not causing much disability, and where the patient's life was still worth living, one should hesitate to force the diagnostic issue. All drastic diagnostic procedures threw an additional burden of responsibility on the doctor. If the present trend continued unchecked the art and science of medicine would become submerged and the doctor would be little more than a glorified mechanic. Dr Walshe concluded "We must not be seduced from the clinical approach. We must use ancillary methods not routinely but for specific reasons, and we must choose the best time to use them."

PERSIAN GULF MEDICAL SOCIETY

A medical congress was held under the auspices of the Bahrain Island Medical Society on Nov. 4, 1948. All the doctors working in the Persian Gulf area were invited, and 36 were able to attend the meeting. This congress, the first of its kind in this area, was in some ways experimental. It was desired primarily to exchange ideas on the aetiology, diagnosis, and treatment of diseases endemic in this area. Secondly, it was felt desirable to explore the possibility of forming a more closely knit organization. Thirdly, it was believed that a meeting of this kind would do much to stimulate medical thinking in a section of the world where there is little access to large medical centres.

The meeting was opened by the chairman, Dr. Robert J. Biggar, chief surgeon to the Bahrain Petroleum Company, Ltd., and president of the Bahrain Island Medical Society. The chairman then introduced the speakers and conducted the discussions based on the following papers: "Report and personal interpretation of the International Industrial Congress at London," by Dr. A. J. S. Perfect, Bahrain Petroleum Company, Ltd.; "Tuberculosis of the peritoneum treated with streptomycin," by Mr. Allen-Mersh, Kuwait Oil Company; "Diarrhoeas encountered in this area," by Dr. H. H. Golz, Arabian American Oil Company, Dhahran, Saudi Arabia; "External otitis," by Dr. A. Anderson, Anglo-Iranian Oil Company, Abadan, Iran; "Back pain—causes and diagnosis," by Dr. Joseph De Lougherty, Arabian American Oil Company, Dhahran; and "Soft penile ulcer," by Major Wm. C. Marrett, jun., M.C., U.S. Army, Dhahran.

An unusually lively discussion followed each address, and all the European, American, and Indian doctors were generally interested in drawing on the experiences of each other in considering these conditions, which are prevalent around the Persian Gulf. A motion was put forward at the end of the meeting that a Persian Gulf Medical Society should be formed from which committees would be appointed for the study of the problems of the area, certain groups to be assigned one phase of a disease for investigation and final reports to be correlated later. Plans were made for the meetings to be held semi-annually.

Preparations and Appliances

AN AID TO ORAL INTUBATION

Dr. R. R. MACINTOSH, Nuffield Professor of Anaesthetics, Oxford, writes: During the past two years I have been experimenting with large-bore oral endotracheal tubes of different shapes. One of the difficulties in passing tubes beyond a

certain size is that the body of the tube obscures the view of the cords through which the tip must be directed. In order to overcome this I thread the tube over a long gum-elastic catheter, the tip of which is then passed through the cords under direct vision (Figs. 1 and 2). Using the catheter as a guide the tube is gently pushed down into position (Fig. 3) and the guide is then withdrawn.

I find this to be useful, too, when for one reason or another—

e.g., a patient with prominent front teeth—exposure of the larynx is inadequate to pass a standard Magill tube easily. Here the tube is threaded over a catheter or even a wire with a bulbous end. The guide can be curved to direct it through the partially exposed glottis, after which the outer tube readily follows into position. Needless to say, it is necessary previously to abolish any relevant reflexes.

Correspondence

Marxist Genetics

SIR,—Dr. H. M. Rose's letter (Dec. 11, 1948, p. 1038) is a characteristic effort at defending an untenable position by the introduction of irrelevant questions. Lysenko has not deigned to criticize contemporary biology, nor has the official U.S.S.R. Academy of Sciences, unless the term criticism is now understood in Moscow to mean vilification. His vague remarks about germ plasm and permeable membranes have nothing to do with the point at issue, nor has his statement that Lysenko's innovations have caused the Russian peasants to depart from their traditional conservatism. Lest these remarks of mine may appear to be somewhat harsh, I venture to quote extracts from *Pravda*, from a translation published on Aug. 27, 1948, in *Soviet News* by the Press Department of the Soviet Embassy in London.

"Michurin's materialist trend in biology is the only scientific one because it is based on the principles of dialectical materialism—the revolutionary transformation of the world in the interests of the people. The Weissmann-Morgan idealist trend in biology is pseudo-scientific because it is based ultimately on the admission of divine origin in the development of the world—on the passive adaptation of man to permanent and unchanging laws of nature. . . ."

"The results of the session of the Lenin Academy of Agricultural Sciences have demonstrated the complete victory, in theory and in practice, of Michurin's teaching over the Weissmann-Morgan trend in biology. The victory of the revolutionary Michurin teaching over the reactionary teaching of Weissmann and Morgan is enormously important for the consolidation of the natural-scientific foundations of the Marxist-Leninist outlook, for the ideological upbringing of the progressive Soviet man, and for the practice of Communist construction. . . ."

"The U.S.S.R. Academy of Sciences forgot the instructions given by V. I. Lenin that 'partisanship' is inherent to materialism, and that materialism, whatever phenomena are being considered, must stand openly and directly on the viewpoint of a definite public group. For Soviet scientists this viewpoint is the interests of the working people, and the basis for their world outlook is dialectical materialism. . . ."

"In an address to the great teacher and leader of the Soviet people, J. V. Stalin, the participants of the conference declared: 'We promise you, Comrade Stalin, to take up a leading position in the struggle against idealist reactionary teachings, to clear all roads for the unimpeded development of progressive Soviet science for the sake of the great aims of our people, for the sake of the victory of communism.'"

There can be no compromise when a political attack is made upon scientific truth, and the fact that Soviet biological science, so-called, is now an instrument merely of political propaganda should be borne in mind when the dialectical materialists attempt to discredit truth in the interest of politics.

At the conference held in 1939 under the auspices of the journal *Pod Znamenem Marxizma* (Under the Banner of Marxism) Lysenko said, "When he grasps Bolshevism the reader will not be able to give his sympathy to metaphysics, and Mendelism definitely is pure, undisguised metaphysics." "The teaching of pure lines," says Professor L. N. Delonei, "is not free from metaphysics." And further: "We must proceed from dialectical materialism," says Professor Polyakov. "It is from this position that we must appreciate what genetics has contributed and what Comrade Lysenko has to offer." "Soviet biologists," says M. B. Mitin, the chairman of the conference, ". . . must master dialectical and historical materialism, and learn to apply the dialectic method to their scientific work." And lastly, and most revealing: "In order to get a particular result, one must want to get exactly that result," says Lysenko. "If you want to get a particular result, you will get it." (These words were quoted by U. Y. Kerkiss, and Lysenko interrupted his remarks to confirm their correctness.)—I am, etc.,

London, W. I.

GEOFFREY BOURNE.

Delayed Diagnosis of Phthisis

SIR.—I am grateful to your correspondents for raising certain points concerning my article, "The Practitioner's Part in the Anti-tuberculosis Scheme" (Nov. 6, 1948, p. 832). It is apparent from Dr. Bertram Mann's remarks (Nov. 20, p. 917) that I did in fact assume incorrectly that his cases were drawn from sanatorium practice. I am glad to learn, however, that there were even better reasons in 1943 for the longer delay found before patients with symptoms consulted their doctors. Perhaps there has not been such improvement in the patients' response to symptoms over the last few years as I had hoped. This would suggest even more strongly that widespread propaganda is urgently needed to educate the population to appreciate the need for action and the possible significance of symptoms. Such a campaign has already been strongly advocated by both Dr. Mann and myself.

Dr. Ian McD. G. Stewart (Nov. 27, p. 957) quotes active cases discovered by mass radiography who proved to have no symptoms. All tuberculosis workers have of course met such cases, and more especially in mass radiography practice, where the present method of using the machines on presumably healthy groups tends to favour the discovery of a higher proportion of symptomless cases than would be found were the whole population investigated: the patient with prominent symptoms is very likely to be off work and attending his doctor when the unit visits his place of work. On the other hand, active cases with no symptoms are relatively rare in clinic practice, which gives a more representative picture. Nevertheless, as I have pointed out, the symptoms in the first instance may be minor in nature, and this was my very reason for stressing the importance of immediate radiography on the slightest suspicion. What other pointer have we that disease may be present? The fact that most of the out-patients of a famous chest hospital "prove to have nothing more serious than bronchitis" is no excuse for failing to refer such cases for radiography. Overstressing the more unusual symptomless case is more dangerous than attaching undue importance to symptoms, because it may lead practitioners to believe their efforts at diagnosis are not worth while.

Finally, I am surprised to see my suggestion that the anti-tuberculosis services are mediocre offending Dr. Mann. Does he really believe that they can be anything else if such delay in diagnosis occurs? How can we deal effectively with cases diagnosed too late to treat? This factor in itself is enough to degrade any service that is supposed to be both preventive and curative. For 25 years B.C.G. has been extensively used on the Continent, and yet we have not afforded it even an adequate trial in this country. Many chest clinics have no x-ray units on the premises. It is not by any means the recognized practice to employ fully qualified almoners in the service, even though tuberculosis is *par excellence* an example of a "social" disease. Following frequently belated diagnosis patients must in most instances wait six to nine months for adequate treatment, since domiciliary collapse therapy and management are only practised on a significant scale in very few areas. Our sanatorium waiting list almost doubled in three years, so that in December, 1947, it reached over 8,000, whilst the beds available for tuberculous patients only increased by 10% during the same period. In some areas patients, having completed their medical treatment, find it impossible to obtain any form of adequate rehabilitation or light part-time employment, so that breakdown following return to work is common. England and Wales at present have some 30 mass radiography units operating, capable of x-raying only once yearly approximately 5% of the population between 15 and 55. Meanwhile the sputum-positive case is forced to live at home or in a common lodging-house through lack of hostel or "night sanatorium" facilities.

I would therefore restate my opinion that we cannot consider the present attack on tuberculosis in this country anything but mediocre. In large part this is due to a widespread failure to appreciate the extent and urgency of the problem. Few people even in our own profession realize that the tubercle bacillus kills over half of those that die within the age group 15 to 45 years—the group of course containing most of our workers' and parents.—I am, etc.,

PETER STRADLING.

London, W.12.

Fluorides and Dental Caries

SIR.—Public interest is naturally aroused when the possibility of a simple cure or prevention for dental caries appears to have become a practical possibility. The connexion between high fluoride intake, mottled teeth, and lowering of caries incidence was first shown in this country by Ainsworth.¹ Further research on the biochemical aspects was carried out in this country by Murray,² and since that time much work has been done in the U.S.A. and elsewhere. The whole matter has recently received a good deal of publicity in the U.S.A., where large-scale experiments on the artificial fluorination of drinking-water and on topical applications to the teeth are taking place.

Your leading article (Sept. 11, 1948, p. 522) was rightly cautious, though a further letter from Mr. Stocker (Sept. 25, p. 617) was more hypothetically enthusiastic. My attention has recently been drawn to certain proprietary preparations containing fluorides that are, or may become, available, and I feel that it would be as well therefore to review the situation as far as we know it, to evaluate the possible benefits and dangers. It would appear that the consistency of the fluorine-dental caries relationship is marked. On the basis of concomitant variation, the epidemiological evidence relative to domestic water supplies appears to be impressive. Within certain limits the fluoride variability cannot be altered without affecting the prevalence of dental caries. It can, I think, therefore be taken as an established fact that fluorine ingestion during the calcification of the teeth plays an important part in caries prevention. This clearly means that the optimum period for its action is during the period of calcification of the permanent teeth—i.e., from birth until the age of about 10.

The evidence so far forthcoming that fluorides applied topically to the teeth are effective is by no means so well marked as that showing their beneficial action when ingested. Recent work in the U.S.A. suggests that topical application may be effective, but the results obtained have been very variable, and even in the Editorial of the *Journal of the American Dental Association* (1947, 34, 700), from which Mr. Stocker quotes, it is stated that the "number of applications, the most effective concentration of the solution to be used, and the duration of the protective effect must still be matters of speculation and investigation." Topical application, though recommended as a possibly beneficial measure, cannot therefore as yet be said to be a well-defined or accepted procedure.

The optimum dosage of fluorides when ingested appears to be one part per million, over four parts per million tending to produce mottled enamel with unsightly discoloration. It is clear therefore that internal administration of fluorides should be carefully controlled, and is not devoid of hazards, as apart from the toxic nature of the fluorine itself administration of extra fluorine where a water supply already contains a sufficient quantity may produce severe disfigurement with ineradicable mottling of the teeth. There is at present very little precise and detailed information relative to the action of fluorides, and, while it has been suggested by Volker³ that the solubility of the enamel is decreased by the fluoride ions replacing certain more soluble ions in the outer layer of the enamel surface, other workers believe that it acts by inhibiting enzymes, which may arrest any local acid production.

In 1947 the American Dental Association vetoed the use of all proprietary preparations for topical application until further evidence was forthcoming. As far as I know this veto has not yet been lifted. To summarize the state of our present knowledge, therefore, it can be said that:

- (1) Optimal fluoride ingestion appears to inhibit dental caries when its ingestion takes place during the period of calcification of the teeth.
- (2) The evidence that topical application following eruption of the teeth is beneficial, though promising, is as yet by no means conclusive.
- (3) The mechanism by which it acts is not yet fully understood, and the optimum strength of solution, frequency of application, and duration, if any, of effect are as yet unknown.
- (4) Ingestion of excessive amounts of fluoride leads to very unsightly mottled enamel.
- (5) Fluorine is a toxic substance

With penicillin it was very wisely decided that it should not be released for general use until large-scale controlled clinical experiments had been done to evaluate its worth and limitation. It would be a pity, I feel, if fluorides are to be made avail-

to the public in this country before adequate trials have been performed. I do not know what proprietary preparations may come on to the market, but in one that I have seen a leaflet is enclosed, from which I quote:

"There is abundant evidence that caries is a 'deficiency disease' due to deficiency, not of vitamins, but of a substance called fluorine, an element which occurs in drinking water, but rarely in sufficient quantity to prevent dental decay."

"The fluorine in drinking water is 'taken up' by the enamel of the teeth, but there is ample proof that the same effect is produced when, instead of being swallowed, fluorine is applied to the teeth in the form of XYZ, and teeth which are regularly and correctly fluorized by using XYZ are highly resistant to caries. This effect quickly becomes evident by the disappearance of 'decay spots,' and of toothache arising from them."

It is admitted that this preparation states on the outside of the box that it is supplied only on a medical or dental prescription. At the same time the statements contained in the leaflet are so clearly unjustified that much harm might ensue. Surely it would be wise to take a leaf from the American book and ban the use of such preparations until further evidence becomes available.—I am, etc.,

London, W.1.

Penicillin Dosage Schedules

SIR,—Your editorial (Nov. 27, p. 946) raises a number of important issues, the most important of which receives the least discussion. Before the study of antibacterial drugs *in vitro* can be directly applied in clinical medicine certain preliminary comparisons must be established. With respect to the drug the four relevant factors are: the bacterial growth phase in which the drug is applied, the bacterial sensitivity to the drug at that and any subsequent growth phases, the concentration of the drug, and the time during which the drug is allowed to act. For a direct *in vivo* comparison to be valid it must be shown that these four factors correspond. Besides this, it must be shown that the growth of the bacteria is similar in the two environments and that, in both, drug-resistant variants are equally likely (or unlikely) to be "favoured."

It is correct to state that in a fluid culture receiving penicillin before incubation (i.e., during the stationary phase of the organisms) and then incubated and observed at intervals staphylococci of the "naturally sensitive" variety are more rapidly killed (as detected by lysis) by small than by large lethal doses of the drug. This is shown for instance in the nephelometric studies of Kirby¹ and was directly observed under the incubating microscope by Gardner.² The explanation is that these organisms are far more sensitive to penicillin in the phase of logarithmic division than in the "lag" phase, and practically insensitive in the resting phase.³ It appears that in the presence of high concentrations of the drug the organisms do not so readily pass into the logarithmic phase, and so a longer time elapses before they are killed, over the range of drug concentrations tested. Certainly cell division proceeds more slowly from the beginning in high than in low lethal penicillin concentrations.⁴ Similarly, when penicillin is added to a full-grown culture or to cells suspended in saline, lysis is again delayed.⁵ If, however, penicillin is added to "sensitive" staphylococci already in the logarithmic phase of division, rapid lysis follows,⁶ even apparently with more than a thousand times the minimal lytic concentration of the drug (Todd⁷). In Todd's work the difference in the rate of lysis of different "sensitive" staphylococcal strains did not appear to be great.

In applying this work to therapeutics we must confess that we still know very little of the rates of multiplication of staphylococci in the human body, although it may reasonably be supposed that in a rapidly developing infectious lesion the multiplication of the organisms is fairly free, and probably slower when the lesion is well localized. These data are manifestly insufficient for accurate comparison with *in vitro* studies to determine "the theoretical ideal" of penicillin dosage schedules. It may be noted that in the mouth, one of the few sites where penicillin action can be closely studied in man, by far the highest rate of bacterial killing is found in the first 10 minutes from starting to suck a penicillin pastille,⁸ suggesting that the majority of the mouth bacteria are actually in a growth phase highly susceptible to fairly high concentrations of the drug. Inoculation studies do not seem to have added much to the solution of this problem.⁹

Surely the fundamental principle is this: that in the present state of knowledge the determination of penicillin dosage

schedules is essentially a clinical study. It was in the pages of this *Journal* that Wheatley⁹ described six (and probably seven) cases of characteristic staphylococcal lesions that responded well to penicillin given in doses up to 200,000 units systemically once or twice daily. One's own experience is similar. It is also well known that localized staphylococcal lesions respond well to relatively enormous concentrations of penicillin established in the pus.¹⁰ If comparison with theoretical work is desired, it may be argued that the studies of Todd amply justify the high-dosage treatment of developing staphylococcal lesions; but such comparisons are essentially misleading because they ignore the part played by the defences of the host. Here there are two factors to consider—the virulence of the resistant variants and the susceptibility of organisms submitted to bacteriostatic concentrations of penicillin.

On the first point the evidence is quite clear: at any rate the great majority of variants with a marked increase of resistance arising in staphylococcal populations are of low virulence and *in vivo*, are easily destroyed by the defences of the host.¹¹ Their low virulence has been confirmed in man (but only for a proportion of strains) by Blair, Carr, and Buchman.¹² Such resistant variants are of course "favoured" in artificial culture and, as they are quite common, the validity of *in vitro-in vivo* comparisons is at once questionable. On the second point there is less evidence, but it is believed that bacteria whose growth is arrested by specific drugs are more susceptible to phagocytosis than while actively growing.

It must also be remembered that a localized staphylococcal lesion is not in free communication with the blood stream (anyone who has "pressed out" a boil will have noticed how much trauma may be inflicted without free haemorrhage occurring). This means that drugs can only reach such a lesion from the blood stream by diffusion through the fibrin barrier deposited under the action of the staphylococcal coagulase. For an adequate concentration to reach the inner part of the lesion a much higher concentration must be present in the blood stream. As these effects remain unmeasured, a high blood concentration is indicated in such conditions. It is known that before the drainage of a "ripe" abscess very little penicillin may diffuse in, but that as soon as the pressure is released the drug is able to penetrate freely.¹⁴ As abscess is the characteristic staphylococcal lesion, this gives good grounds for obtaining as high a blood concentration as possible (even if only for limited periods of time) if the state of tension in a staphylococcal lesion is unknown. It has also been shown that too small concentrations of penicillin seem to stimulate the growth of staphylococci.^{15, 16}

By all means let us study these newer penicillin preparations, but let their proper usefulness as well as their "dosage schedules" be assessed by clinical trials rather than by laboratory studies which, however valuable in another context, are of uncertain relevance here.—I am, etc.,

Montana, Switzerland.

Mallet Finger

SIR,—Perhaps it is not popular to question the economics of some procedures in the practice of medicine to-day, but surely we cannot be such purists as to ignore the financial cost of particular treatments to an individual and the community.

There is one injury which is common at work and in the home—the mallet finger. It is striking how much time can be lost with this condition and I claim a large proportion of it as a result of treatment. In a group of 9,000 workers over the last seven years not a few mallet fingers have been seen, some-

for prolonged local medication

Penicillin Chewing Gum A&H presents penicillin incorporated in a base predominantly mint-flavoured and designed to maintain the potency of the medicament.

When chewed slowly it provides an effective concentration of penicillin in the mouth for three to four hours. It is thus the preparation of choice in the treatment of Vincent's infection, tonsillitis and other buccal and pharyngeal infections due to penicillin-sensitive organisms.

PENICILLIN CHEWING GUM A&H

In packets of six pieces, each piece containing 5,000 i.u. penicillin (calcium salt)

ALLEN & HARBURYS LTD. LONDON E.C.2

TUINAL

A characteristic of any individual barbiturate is that the time required for onset of action is in direct proportion to the length of action. No single barbiturate can produce both a rapid and prolonged effect.

Tuinal, which has applications in obstetrics, surgery, and general medicine, combines the rapid, short action of 'Seconal Sodium' with the more prolonged action of 'Sodium Amytal'.

'Pulvules' brand Filled Capsules Tuinal 1½ grs (No. 303) and 3 grs. (No. 304) are supplied in bottles of 40, 100, and 500.

A WOUND ANTISEPTIC of high efficiency

FLAVAZOLE is an equimolecular chemical combination of Proflavine base and Sulphathiazole discovered in the laboratories of Boots Pure Drug Co. Ltd.

Clinical results have shown that Compound Flavazole Powder consisting of Flavazole 2%, Sulphathiazole 98%, is most effective in controlling

infections in wounds. Available in tins containing 12 sterilized sifter envelopes of 5 G. ready for immediate use, and in bottles of 15 G.

FLAVAZOLE is also available as a powder for preparing neutral solutions for irrigation and for dilution with a sulphonamide for local application. Bottle of 25 G.

COMPOUND FLAVAZOLE POWDER

In the vitamin alphabet, 'A' and 'D' are the recognised initials of protection. Winter's arrival underlines the importance of these vitamins—and of the Adexolin preparations which present A and D at high concentration. Adexolin Capsules are meant primarily for adults. The normal routine is one or two capsules daily throughout the cold months, with a larger dose if infection threatens—for instance, when the onset of a cold is suspected. For infants and children, Adexolin Liquid provides an equally sound and economical routine, fortifying the body's resistance to infection through the natural mechanisms.

Capsules 4,500 i.u. vitamin A,
900 i.u. vitamin D per capsule.
In tins of 25 and 100.

Liquid 12,000 i.u. vitamin A,
2,000 i.u. vitamin D per cc.
In 14 cc. and 2 oz. bottles.

Watson X-Ray Apparatus WORKS RELIABLY AND WELL

Long experience has taught us how to make X-ray apparatus on which the user may rely implicitly. Electrically and mechanically, it is built for continuous use under all climatic conditions with the minimum of interruption for maintenance.

Radiologists throughout the world specify Watson equipment certain in the knowledge that it embodies the best features of contemporary design.

We will gladly submit proposals for the layout of modern X-ray departments on request.

times immediately and sometimes from days to years after the injury. It is difficult to find a case where extension has returned to the terminal joint. Some of these have had the appropriate plaster-of-Paris fixation, others have had operation, and one an *arthrodesis*. Others have had no treatment whatever, continuing at work, and the impression has been that the best result is in the latter class. All have had jobs where the residual dropping has not been likely to interfere with their skill to any appreciable extent, and the impression is that those who have carried on work, and where there has been no effort to correct the deformity, have quickly accommodated themselves to it.

Some idea may be reached of the economic factor from these two cases. A man was under treatment for one year for this condition in the little finger and lost some three months from work during this time. A woman injured at work on July 6, 1948, is still away from work—five months of treatment by plaster and operation. Incidentally, although a part-time worker averaging 35s. a week, she receives 45s. a week for an industrial injury, not because she is malingering but, it is suggested, as a result of over-enthusiastic treatment. These cases, by virtue of the form of the plastic fixation, are difficult to accommodate in work while under treatment.

While it is realized that this letter gives impressions and not statistics, it may be that it will stimulate discussion and inquiry into treatment given without thought to financial disability, and possibly without knowledge of the probable ultimate function. It would be desirable to carry out a planned investigation of this problem.—I am, etc.,

Birmingham.

W. J. LLOYD.

Pre-suppurative Amoebic Hepatitis

SIR,—Dr. James T. Harold in his letter (Dec. 11, p. 1034) states that no recent record exists of an amoebic liver abscess in a patient who has never left this country. He (and others) may be interested to hear of a case in the Queen Elizabeth Hospital, Birmingham, at the present time. The patient had a large sub-phrenic abscess which was opened and drained. He gave a history of a fortnight's diarrhoea; proctoscopy led to the discovery of ulcerations of the rectum. A portion of ulcerated epithelium was removed and upon examination proved to contain cysts of *Entamoeba histolytica*. The patient has never been out of the country in his life, and for the last ten years has never even been out of Worcestershire, except to come to this hospital.

I owe my thanks to Mr. A. L. D'Abreu, whose patient he is, for allowing me to write this letter.

—I am, etc.,

Birmingham.

FRANCIS LOWE.

Curare in the Treatment of Tetanus

SIR,—In view of the current interest in the treatment of tetanus with curare compounds the following brief case report may be of value.

A patient, a boy of 9, was admitted to hospital after a three days' history of trismus, with painful muscular spasms for twelve hours. On examination he showed marked trismus and a considerable degree of rigidity of the spine, especially marked in the cervical and upper thoracic region. Muscular tone was raised generally, and reflexes were brisk. Examination of the child was sufficient to provoke an attack of muscle spasm with typical "risus sardonicus" and acute pain in the cervical region.

Tetanus antitoxin (24,000 i.u. diluted with 10 ml. of pyrogen-free water) was administered intravenously at once and a further 30,000 i.u. given intramuscularly. The patient had been given 3,000 i.u. before admission to hospital without ill-effect, so chances of anaphylactic shock were considered negligible. At the same time sedative treatment was instituted by giving soluble phenobarbitone, gr. 1½ (0.1 g.) six-hourly, and 0.05 mg. d-tubocurarine chloride also six-hourly.

The following day the dose of 30,000 i.u. of antitoxin was repeated intramuscularly. The patient had had no further spasm and was able to swallow semi-solids without difficulty. Treatment with curare and soluble phenobarbitone was continued, and after three days the time interval between doses was lengthened until at the end of seven days the drugs were being given twelve-hourly. Treatment was then discontinued. Apart from a slight restriction of jaw movement the child felt well and was discharged one week later.

This case shows two points of interest. (1) The dose of curare compound used was so small that there was no danger of interfering with respiration, yet it was sufficient to abolish spasm in a fairly advanced case. (2) There was no obvious mode of entry found. The child's arms and legs showed a few healed scratches only, and no other wound was found. From this point of view it is interesting to note that a farm horse at the child's home contracted tetanus a year ago and was cured with tetanus antitoxin, suggesting a heavy implantation of the child's environment with the bacillus.—I am, etc.,

Barnet-in-Furness.

ANNE L. BARLOW.

Anaesthesia in Ludwig's Angina

SIR,—The danger of intravenous anaesthesia for incision of acute inflammatory swellings of the neck has long been recognized, yet only recently a case was described to me which very nearly ended tragically.

A resident, called upon to give the anaesthetic to a case of Ludwig's angina, consulted the latest edition of a standard surgical textbook and found that intravenous anaesthesia was recommended as the method of choice. Accordingly he administered "pentothal." Breathing at once became obstructed and extreme cyanosis developed. The surgeon proceeded to perform tracheotomy, but after he had made the skin incision the anaesthetist managed to persuade an endotracheal tube past the obstruction into the trachea. This patient made a complete recovery, though only after twenty-four hours of delirium. Before operation, I am told, there was visible oedema in the floor of the mouth, and in this and in similar cases one might expect some oedema to be present in the pharyngeal wall and in the glottis without necessarily causing any symptoms of respiratory obstruction prior to anaesthesia.

The sequence of events in these cases would appear to start with laryngeal spasm. Pentothal is known to increase the laryngeal reflex, and the presence of oedema in the nearby tissues probably provides the exciting factor. Asphyxia resulting from this spasmodic occlusion of the larynx gives rise to venous engorgement of the head and neck, which increases the oedema and finally results in complete obstruction. Obstruction will still be complete even when the spasm of the larynx passes off, as it invariably does before death. It follows, therefore, that in the absence of tracheotomy or intubation the patient must die.

Anaesthesia for these cases must be non-irritating and not liable to give rise to laryngospasm. Cyclopropane or chloroform given with plenty of oxygen are the agents which best fulfil these requirements. It is scarcely necessary to add that instruments for tracheotomy should be ready in every case of this nature. It seems deplorable and very hard on young residents, not to mention patients, that such misguided advice should be perpetuated in recent editions of reputable surgical works.—I am, etc.,

Sutton, Surrey.

JOHN H. WILLIS.

The McNaghten Rules

SIR,—Dr. Henry Yellowlees (Dec. 11, 1948, p. 1034) has written without fear of offence, and I am sure that he will permit me to do the same. He has produced the usual stock arguments, for which I am most grateful since it allows me to show their flimsiness. It is surprising, for instance, to see the old one, so beloved of the cheap press, regarding "Law from Harley Street." Whether Dr. Yellowlees likes it or not, the law is dependent on medical opinion. First, the accused may be unfit to plead. How is that decided? On a doctor's opinion. Secondly, even if condemned to death, there is a proviso in the Criminal Lunatics Act, 1884 (Section 2, subsection IV), by which two or more legally qualified practitioners can be asked to examine the prisoner and inquire as to his insanity. So the law does come from Harley Street.

I am sorry that Dr. Yellowlees would hesitate to certify a patient who "stated that his father had been insane and that he himself had impulses to murder children." I am certain that no judge in chambers would allow an action for malpraxis against me if I certified a man for such impulses, and no commissioner in lunacy would dare to question such a certificate. The reasons for certification are that the patient is (1) dangerous to himself or others, or (2) in need of care and treatment. Most patients in need of treatment will go voluntarily to hospital, and in general patients are certified because the

This does not mean that they are dangerous all the time, but have brief impulses, potentially homicidal or suicidal, etc. *What is more contradictory than that a patient should be certifiable because he is dangerous and yet we should regard him as responsible if he kills anyone?* How a competent lawyer or psychiatrist can accept such a proposition is beyond my comprehension.

I am sure that Dr. Yellowlees has a wide legal acquaintance, but what a pity he never knew Lord Bramwell, who stated, "Nobody is hardly ever really mad enough to be within the definition of madness laid down by the judges' answers"; or Lord Chief Justice Coleridge, who said, "The judicial decisions on questions of insanity were bound by an old authority which, by the light of modern science, was altogether unsound and wrong." The young barristers I meet express uneasiness and dislike of the rules.

Dr. Yellowlees accuses me of expressing "a travesty of the facts." Well, let them speak for themselves. I cannot burden your columns with long lists of disputed cases, but to examine two recent ones: First, a young man whose father has been psychotic and who himself was always odd enters a hospital ward and removes a child he has never previously seen. He smashes it to death against a wall. Is this insane act regarded as a sign of mental disease and the man sent to Broadmoor? No, the M'Naghten rules are invoked and he is hanged. The other case is of a young man who has been an obvious psychopath since puberty. He has been in Borstal and thrice lost commissions in the Services. He is sexually abnormal—a sadist and handkerchief fetishist. He flogs a woman to death with a riding quirt. Then he cuts a girl to pieces. These senseless crimes are not regarded as signs of insanity, and the man is not sent to a criminal mental hospital. No, the M'Naghten rules are produced and he is hanged. If these men were sane, then my criterion of sanity is all awry.

May I state that I am not trying to interfere with the expert's duty to assist the court, but to persuade politicians to alter the law to something sensible, logical, and in accordance with modern psychiatry, when I suggest that legal and medical insanity should be regarded as identical? May I offer the hope that both Dr. Yellowlees and I shall live to see this accomplished?—I am, etc..

London, W 1

CLIFFORD ALLEN.

Femoral Hernia

SIR,—I should like to express my agreement with Mr. Andrew G. Butters (Oct. 23, 1948, p. 743) in his advocacy of the low operation for femoral hernia, though one should always be prepared to use the high (Annandale) approach in the exceptional case. Thorough freeing of the neck of the sac, as he stresses, is very important to secure adequate reduction.

I think the best technique to use is that described long ago by Macewen,¹ who used a puckering stitch to transform the sac into a pad to block the upper end of the canal. Instead of the single strand he used I prefer to run a catgut suture up one side of the sac across the neck and down the other side. When this has been done the sac with its adherent fat is reduced into the abdomen, and with one finger blocking the femoral canal each end of the suture is pulled tight so that the sac is formed into a pad, and the ends of the stitch tied. A pull on the catgut will tell in the majority of cases that the canal is safely closed, in which case, when a local anaesthetic has been used, the patient may safely walk out of the theatre.

I am less inclined to agree with Mr. Butters's view that because a femoral hernia usually makes its appearance at the age of 50 years or later the majority of femoral sacs are acquired.

Some years ago I had charge of a woman of about 50 years of age who was admitted with a mass in the right iliac fossa and a recently acquired, rather tense right femoral hernia. The former was regarded as an appendix abscess and expectant treatment decided on. After about a week she became anxious to go home, but it was considered that the femoral hernia at least was a danger, and it was explored. At operation a thin sac was found to be filled with blood-stained fluid. The neck of the sac was so narrow that some persuasion was required to introduce a probe-ended dissector into the abdomen, and when this was done blood-stained fluid trickled from

the abdomen. Laparotomy then revealed similar fluid in the abdomen and a fixed growth apparently arising from the right ovary. Such a sac could hardly have been acquired, and it is easy to imagine a congenital sac with a narrow neck remaining dormant till, with advancing years, loss of supporting fat in the femoral region allows a tongue of omentum to slip down and produce a hernia.

Incidentally, it may be mentioned here that a useful retractor for the suture or transfixion of the neck of funicular sacs may be devised from the common or kitchen four-pronged fork, the ends of the two medial prongs being bent away from the midline of the instrument to prevent their being entangled in the tissues. The instrument is slipped over the sac, and the assistant uses one hand to press it firmly against the abdomen while his other hand pulls the sac firmly forward. The abdominal contents are kept from entering the sac and the surrounding tissues clear of the surgeon's needle.—I am, etc.,

Birmingham

Nephritis in Textile Workers

SIR,—Dr. G. Herdan (Dec. 18, 1948, p. 1083) makes some statistical criticisms of my article on this subject (Nov. 15, 1947, p. 771), but I cannot agree with his conclusions. In the first place he suggests that my series of personal cases is not a representative sample of the population because it does not show deaths from nephritis or from malignant hypertension in the older age groups. Evidently Dr. Herdan is not very familiar with renal disease or he would know that both conditions are extremely rare over the age of 50. I do not remember ever seeing a case of malignant essential hypertension over the age of 60. Benign essential hypertension does not occur in my table because it does not cause death from renal disease. It is largely for these reasons that I am so certain that the Registrar-General's deaths from so-called nephritis are mostly not renal deaths at all.

I cannot agree either with Dr. Herdan's second point that deaths from nephritis in textile workers should be compared with deaths in the whole population rather than with deaths in social classes III and IV, from which textile workers are drawn. Surely if there were any increased incidence of nephritis due to occupation rather than social circumstances my comparison is the only one by which this could be shown?

Finally, I do not wish my statistical analysis to be taken as proving anything, as I clearly said in my conclusions. The whole paper was merely written to expose what is still the greatest fallacy of all statistical argument—namely, the facile assumption that the data from which the statistics have been compiled are sound.

The question of renal disease in textile workers is now being investigated in the field by Professor Lane's department, and I have no doubt we shall have the answer shortly.—I am, etc..

Manchester

ROBERT PLATT.

Treatment of Simple Ganglion

SIR,—The present teaching on the subject of simple ganglia is inadequate, for in many cases a wrong diagnosis is made—e.g., fibroma, neuroma, osteoma, chondroma, bursa, and even sarcoma. In a few cases seen diagnostic x rays have been taken and, in some, unfavourable prognoses had been given. The condition is common in factory workers, steel workers, miners, etc., and there can be little doubt that heavy work and strain are aetiological factors.

The treatments usually advised in surgical textbooks are: (1) Do nothing in the hope of spontaneous disappearance. This is unsatisfactory, for if a patient comes to a doctor with a swelling he expects something to be done about it. (2) Hitting the swelling with a hard object such as a book. This is clumsy and possibly dangerous. In many cases—e.g., in the palm of the hand—it is often impracticable. This treatment should cease to find a place in modern textbooks. (3) Aspiration and injection of a sclerosing fluid. This is painful, disabling, and often unsuccessful. It is not to be advised. (4) Incision with a tenotome and expression of the contents. (5) Excision of the swelling. This is a major surgical procedure, necessitating a general anaesthetic, most careful asepsis, and subsequent rest. It

leaves a permanent and often unsightly scar, and is often followed by recurrence.

Most surgical textbooks advise excision of the swelling as the best treatment. No mention is made of what is by far the simplest, easiest, and most satisfactory treatment. In the great majority of cases ganglia can be cured by the application of firm, steady pressure with the palmar aspect of the end of the thumb to the swelling—the thumb being supported by the fully flexed fingers. The part should be resting on a hard, firm base, such as a table or desk. Tremendous pressure can be exerted, but it is accurately controlled, and, as the swelling goes, it is quickly and automatically relaxed. In superficial swellings in thin patients the jelly can be seen to disperse in the tendon sheath. The ganglion is a collection of jelly in a diverticulum of the sheath.

Some discomfort, hardly amounting to pain, is felt by the patient, but he may be reassured that the surgeon will possibly feel as much discomfort. It is important that the surgeon should not strain or damage his own metacarpo-phalangeal joint, for considerable pressure has sometimes to be applied. If the patient is unwilling to accept the discomfort involved, or if very considerable pressure is necessary (and this is not usual), local infiltration with procaine may be used. In a very nervous subject a little gas may be administered or intravenous "pentothal," though this should rarely be necessary. Most cases are very easy to do, but a few are difficult, and it is not always possible to foretell which will be the easy ones. Generally the ganglia with a bony background are easy, and those with a soft-tissue background are not so easy.

In the great majority of cases this treatment is successful, but in a few—those in which the opening into the tendon sheath is small or the jelly very solid—the swelling cannot be dispersed. In such cases puncture of the swelling with a fine tenotome after infiltration with procaine and subsequent pressure is the treatment to be adopted, and is effective. The results of treatment are very good indeed: most cases can be dispersed, and few recur. If there is a recurrence, the treatment is repeated. Excision is not the best treatment and should seldom, if ever, be necessary.—I am, etc.,

ERIC COLDREY.

Temperature Recording

SIR.—It is interesting to see confirmed by Professor Alan Moncrieff and Dr. B. J. Hussey (Dec. 4, 1948, p. 972) what one was taught as a student about temperatures. I should like to add a general practitioner's comments. The article does not emphasize the need to test thermometers. I once found a variation of 2° F. (1.2° C.) in a dozen thermometers certified as accurate. Position does not seem to me important, except to avoid the cavernous, sweat-soaked axillae of neurotics, also the rectum. Perhaps I am exposing some psychological kink when I say that I feel interference with the rectum should be limited to those digital examinations which can only be made P.R.

My practice is to use any one of three positions—the groin in children, the mouth in older children and adults, and the axilla only when there is an obvious throat or mouth condition involving gross risk of cross-infection. I make a correction for groin or axillary temperatures and record all readings as though they were buccal.

The time factor is rightly emphasized. I think I take not less than thirty temperatures a day, and allow at least two minutes for each—more, if there is doubt. This involves an hour a day; but it is not difficult to use this time pulse-recording, examining ears, soothing relatives, etc. It is worse than useless—and, I am afraid, a common fault in hospital and general practice—to make hasty and inaccurate temperature records.

Finally, one should not forget that the "normal" temperature is merely an average. On a hot summer evening in London the temperatures of twenty patients with "afebrile" disorders were between 98.6° F. (37° C.) and 99.2° F. (37.3° C.); whereas off the coast of Newfoundland on a winter morning I recorded a succession of temperatures below 96° F. (35.6° C.). Apart from climate, many patients vary from the normal. For this reason I take the first opportunity to record the normal temperature and pulse of a patient—e.g., when he brings his panel card. In this way one knows that even a pulse rate of 60 may be tachycardiac and a temperature of 98.6° F. subnormal. I have a great respect for a thermometer—if it is a good one used intelligently.—I am, etc.,

Wembley, Middlesex.

M. C. ANDREWS.

End of Compulsory Vaccination

SIR.—To many of us Dr. C. Killick Millard will always be associated with vaccinia, and it was a pleasure to hear his voice again (Dec. 18, 1948, p. 1073) in vindication of his well-known views on the subject. While I have subscribed to some of his arguments in the past I do not share his complacency about the future. Compulsory vaccination of infants, despite the exemption clause, was a procedure that few medical men could push with a clear conscience. I have always felt that the advantages, disadvantages, and possibilities should be clearly explained to the parent, and that no doctor should take the responsibility of advising yea or nay.

Mass vaccination of a community threatened with smallpox is seldom, if ever, justified. At the same time vaccination is the specific measure against smallpox and should be employed promptly and accurately where indicated. The medical officer of health who panics and advises mass vaccination is like the sportsman who "browns" the covey instead of picking his birds in front, and the results are comparable. If—to follow up the simile—he fails to pick up the wounded birds (those inoculated but not yet showing a "take") or permits them to escape into the next parish, the results may be disastrous. I have not been impressed by the claims of those who have attempted to justify mass vaccination, not only for the reasons which Dr. Millard gives regarding self-limitation of smallpox, but also because of the fact that in most instances the measure was adopted too late to be of any effect. It is just possible that compulsory vaccination reduces the effect of the first impetus of an epidemic and thus gives us time to mobilize our forces, but it may be argued that it may mask the initial infection.

Medical officers are now expected to "push" vaccination as they do immunization against diphtheria. The only reason which I, personally, can advance for the vaccination of an infant is that in later life, should he be compelled to be vaccinated, he will have less risk of contracting encephalitis. Similarly, I would feel bound to point out the danger of primary vaccination to an adult in need of protection. The obvious policy is to produce a vaccine which will not carry a risk of causing post-vaccinal encephalitis and which we can advocate with confidence.—I am, etc.,

Kirkcaldy, Fife

JAMES R. W. HAY.

POINTS FROM LETTERS

Proof-readers' Disease

Dr. J. S. MEIGHAN (Bridge-of-Weir, Renfrewshire) writes: I claim to have discovered a new disease—proof-readers' carelessness. Almost all books now published in this country have many more printer's errors than before the war. . . . The disease is not confined to books but also affects newspapers. . . . How is it that almost any American book one picks up, or book printed in our Dominions, has much fewer misprints?

O Russia! O Mores!

Dr. ASHLEY A. ROBIN (Burley-in-Wharfedale, Yorks) writes: I regret having to take you up so soon after criticizing your reviewer Dr. Darlington, but after reading the annotation "O Russia! O Mores!" (Dec. 4, 1948, p. 991) I wonder whether the real issue is one of an individual bad reviewer or whether it is a fact that this review was in keeping with your recent treatment of Soviet science in general. On Aug. 30, 1947, in a leading article entitled "Ourselves and the Russians," you dealt with an article entitled "The Sham Political Neutrality of the British Medical Journal" which had appeared in *Meditsinsky Rabotnik*. The *British Medical Journal* was accused of "a tendency to preserve silence on and to ignore the achievements of Soviet medical science . . . and to publish mendacious information." This was hotly denied, and a "sincere desire to inform British readers of the advances and the contributions of Russian medicine" was expressed. Since then there have been four contributions dealing with Soviet affairs. These articles were uniformly hostile. The last article by a Soviet contributor was on Dec. 8, 1945. In it V. Parin, reporting the Soviet Academy of Medical Sciences, says: "All the speakers mentioned the achievements of medical science in Europe and the U.S.A. . . . and expressed great interest in foreign equipment and in the foreign scientific press." I trust that patience is a Russian virtue. . . .

Obituary

LIONEL COLLEDGE, F.R.C.S.

We announce with regret the death, on Dec. 19 at the age of 65, of Mr. Lionel Colledge, one of the most distinguished figures in otology and laryngology in this country. Mr. Colledge, who died at his home in Upper Wimpole Street, was for many years a valued contributor to the *British Medical Journal*.

The son of Major John Colledge, of Cheltenham, he was educated at Cheltenham College and Caius College, Cambridge. Lionel Colledge qualified M.R.C.S., L.R.C.P. in 1908 as a student at St. George's Hospital, graduated M.B., B.Ch. in 1910, and took the F.R.C.S. a year later. During the 1914-18 war he served with the R.A.M.C. in France, and after a short period in command of a casualty clearing station he became aural surgeon to the First Army. He was on the staff of the Hospital for Diseases of the Throat in Golden Square, and he was consulting surgeon to the Ear and Throat Department at St. George's Hospital. Later he was also surgeon to the Royal Masonic Hospital and the West End Hospital for Nervous Diseases. The rules of St. George's Hospital made it necessary for him to retire at the height of his professional activity, but his election to the staff of the Prince of Wales General Hospital at Tottenham allowed him to continue his hospital work there. In later years Mr. Colledge acted as consultant to the Cancer Hospital, where he was able to continue the work on malignant disease of the larynx and pharynx which he had begun early in his career in association with St. Clair Thomson. Together they published in 1930 a monograph on cancer of the larynx which was one of a series in the Anglo-French Library of Medical and Biological Science. This work included the material which had already been presented by Colledge as Semon Lecturer in Laryngology at the University of London in 1927.

In the recent war Mr. Colledge came to the assistance of St. Mary's Hospital and at the same time acted as consulting otologist to the Navy. He wrote authoritatively on a variety of subjects and had a wide knowledge of the literature of his specialty. He contributed articles to the *British Encyclopaedia of Medical Practice* and to Maingot's *Postgraduate Surgery*. His *Guide to Diseases of the Nose and Throat* was written in collaboration with C. A. Parker, and his work on the surgical treatment of paralysis of the vocal cords, on which he assisted Sir Charles Ballance, is well known.

He acted as editor of the Section of Laryngology in the *Proceedings of the Royal Society of Medicine*, and there his revisions, although drastic at times, were of benefit both to author and readers. He was one of the founders of the British Association of Otolaryngologists, and its first vice-president, and he held the presidency of the Sections of Laryngology and Otology of the Royal Society of Medicine.

He married Margaret, the daughter of the late Admiral J. W. Brackenbury, and they had two children. Their son, Maule, lost his life while serving with the Royal Air Force in Europe. Their daughter, Cecilia Colledge, is world-famous as a skater.

Mr. V. E. Negus writes: To some it appeared that Colledge was interested in the major surgical aspects of his specialty to the exclusion of the minor or less serious diseases; this supposition was, however, somewhat exaggerated. Although known more particularly for his interest in malignant disease, yet those who followed his work admired his ability in diseases of the ear and in many other directions. In research, too, Colledge had a share, working with Sir Charles Ballance on the problems of nerve anastomosis. They performed many experiments on monkeys and apes, especially with regard to paralysis of the larynx; anastomosis of the phrenic to the injured recurrent laryngeal nerve promised success, but mistiming in the larynx of the human subject gave disappointing results.

Those who knew Colledge only at a distance may have thought him forbidding at times, but those who held his friendship knew that close below the surface lay a benign and generous character, allowing him to entertain his friends graciously and to see the lighter side, with keen appreciation of any humorous aspect. As

house-surgeon to him for a time at Golden Square, I found sympathy and tolerance, with ready support and help in difficulties. On foreign travel there was no better company. Some trivia annoyances, such as the rattling of cutlery on a table in the dining car, irritated him, but these minor traits accentuated the bigger and better aspects of his character. He was fond of visit to foreign clinics, and as a member of the visiting Association of Throat and Ear Surgeons of Great Britain, and of the Collegium Oto-Rhino-Laryngologicum, he made many trips, on some of which his wife accompanied him and acted as a skilled interpreter in a number of languages. His occasional relaxation was shooting on a Saturday, but non-medical holidays were rare. Work was his constant occupation, and much reading gave him a critical judgment of great value. In discussions he was stubborn and somewhat dogmatic, but his judgments were based on a wide experience and were adopted only after close inquiry into the methods of others.

It was distressing to find that physical disabilities after his critical illness partially cut him off from the active life he had led; heroic and courageous determination, supported by the devotion of his lady attendant, kept him in touch with some of his interests. To the end of his days he visited the Royal Society of Medicine and the Medical Society of London, with both of which he had been intimately connected and for which he had done so much. Widely known to many more than those of his own special branch of medicine, Colledge was esteemed highly and most of all by those who knew him best. He laboured unceasingly for the specialty of his choice, and the result of his labours is a lasting memorial to him: the large number of those who attended his hospital practice and studied his writings will for long bear witness to his influence.

W. M. M. writes: Laryngology has sustained a very great loss in the death of Lionel Colledge; he made laryngectomy appear very easy, and his results were wonderful. His hobby was work: he seldom left London. Any evening he was to be seen walking to or from his house with stick or umbrella over his arm, his hat seldom on his head but carried. He was a man who wanted knowing, but, once known, he was always a real friend. Though reserved, Lionel held firmly to his own view due doubtless to his extensive and encyclopaedic knowledge of the literature of his specialty.

LUCIEN VAN HOOFF, M.D.

Few who are interested in tropical medicine can fail to have heard of Major-General Lucien-Marie-Joseph-Jean van Hoof who died in Antwerp on Dec. 6. Van Hoof was born in 1890 at Malines. He served as a volunteer throughout the war of 1914-18, being decorated with the Belgian croix de guerre. Later he joined the medical service of the Belgian Congo, becoming its médecin en chef in 1934. He retired from Belgium in 1946 and was appointed a professor at the *Institute of Tropical Medicine* Prince Léopold in Antwerp. The high efficiency of the medical services in the Belgian Congo and the ever-rising standard of health of its inhabitants are very largely due to van Hoof's great powers of organization. The research institute which he was responsible for creating in Leopoldville is without a rival in tropical Africa, while the housing of Africans in cities such as Leopoldville, Stanleyville, and Elisabethville, a question in which he was deeply interested, provides an object lesson which many British colonies might well study with advantage. Although in his last years in Africa he was naturally encumbered with many administrative duties, he remained throughout an active research worker. He was particularly interested in trypanosomiasis, and in the past few years he had carried out important original investigations on the prophylaxis of sleeping sickness with pentamidine. The investigations are likely to play an important part in the control of human trypanosomiasis throughout Africa. During the war years van Hoof did much to facilitate close co-operation between the British and Belgian authorities. He was a well-known figure at many inter-Allied conferences on yellow fever and trypanosomiasis, and his knowledge and advice were always of the utmost value. The Congo troops who served both East and West Africa owed much of their high standard of fitness to van Hoof's thorough knowledge of how to preserve the health of the African under the most trying tropical conditions. Those who are fortunate enough to have visited Leopoldville

will long remember van Hoof's kindness and unbounded hospitality. He had many British friends, who will wish to join with their Belgian colleagues in mourning the loss of a great man whose work has done much to improve the health of tropical Africa.—G. M. F.

Dr. NANCY GWENDOLYN SHUBIK died suddenly on Sept. 20. She was the daughter of Mr. and Mrs. F. S. Rogers, of Newport, Monmouthshire. She entered the Welsh National School of Medicine in 1935, and qualified M.R.C.S., L.R.C.P. in 1939, taking the D.P.H. in 1941. After two years in clinical and public health work she was appointed demonstrator in pathology at Cardiff. In 1944 she became junior lecturer in pathology at the British Postgraduate Medical School, where she remained until 1945, when she joined the Indian Medical Service. She did excellent work in India, and on returning to England in 1947 she again took up laboratory work and was engaged in neuropathology in Sir Hugh Cairns's department at Oxford. Dr. Shubik was an enthusiastic worker, always determined to seek the exact answers to the problems that she met in her work. She published, in collaboration with Professor E. J. King, several papers on silicosis. She was a member of the Pathological Society of Great Britain, and many of her fellow members will sadly miss her presence at the Society's meetings.

Dr. FREDERICK HENRY WADDY, who died on Nov. 17 at the age of 79, was the third son of the Rev. J. T. Waddy and a nephew of the better-known Judge Waddy, Q.C. Following a brilliant scholastic career at The Grove, Kingswood, and Wesley College, Sheffield, he studied medicine at Glasgow University, graduating M.B., C.M. in 1893 and proceeding M.D. in 1896. After several house appointments he was for three years senior resident medical officer at Fivale Hospital, Sheffield, in which city he started in general practice in 1900. During these early days he obtained the D.P.H. but nevertheless elected to remain in practice, retaining his association with the Guardians as a parish doctor and public vaccinator. As a practitioner he followed his profession for nearly thirty years with a degree of integrity and philanthropy that led to his being profoundly respected. A man of modest and retiring personality, he was widely accomplished in other arts and sciences than that of medicine, being highly proficient in mathematics, astronomy, meteorology, and botany. He was revered as a Wesleyan preacher and known as a scholar in theology, Greek, and Latin. Such was the man who became a casualty at the age of 55. Labouring under the progressive disability resulting from encephalitis lethargica, he was obliged to retire from active professional work three years later, in 1927. With deep distress his relatives and professional colleagues witnessed the decay of his mental capacity for a further twenty-one years, until he died peacefully while asleep at the Northampton home of his daughter, Dr. Ethel Waddy. He leaves also a widow and two sons, the younger of whom is a member of the profession.—D. C. W.

Dr. HARRY TRIST ROBERTS died at his home in Pangbourne on Nov. 20 at the age of 77. He was educated at University College and qualified L.D.S. at the Royal Dental Hospital, afterwards going to St. Mary's Hospital, where his father, Dr. Owen Roberts, and his two brothers had qualified previously, to obtain his medical diplomas. He practised for many years in Harley Street and at his house in Kensington. He was a hard worker, and his genial and sympathetic nature won him hosts of friends and he was greatly esteemed by his patients. He was a keen sportsman, and played cricket for the M.C.C. and rugby for the Wasps and Kensington. Dr. Roberts was a Freeman of the City of London and a Girdler. He took a great interest in the activities of the B.M.A., until he developed osteoarthritis and became hopelessly crippled and was compelled to give up his practice in 1942. He leaves a widow, to whom will be extended the sympathy of his friends and colleagues.

Dr. TOM ENTWISTLE FERGUSON, of Bishop Auckland, died on Nov. 28 at the age of 63. Born at Bolton, of Scottish ancestry and of an old medical family, he qualified at Glasgow in 1911. After a period as house-surgeon at Stanley Hospital, Liverpool, and a tour as a ship surgeon, Dr. Ferguson entered general practice in Bishop Auckland in 1913. He joined the R.A.M.C. in 1915 and served in France and Italy, resuming practice in 1919. He joined the B.M.A. in 1912, and his colleagues honoured him with the chairmanship of the Bishop Auckland Division in 1931-2. Not only in his term of office but at all times Dr. Ferguson gave ungrudging and loyal service to the Association. He took a lively interest in the Bishop Auckland Cottage Hospital, of which he was honorary physician and surgeon. Many patients, especially in the days when distance

and transport were more important factors than they are now, have been grateful for his skill as a surgeon. From 1939-45 Dr. Ferguson was engaged in the work of civil defence—training ambulance students and taking charge of a mobile unit. Golf was his recreation, but had to be forsworn after the first attack of his terminal illness. Dr. Ferguson retired from practice on May 1, 1948, and was succeeded by his son, Dr. A. J. A. Ferguson. Tom Ferguson's death has deprived many of his colleagues of a personal and valued friend and his patients of a devoted physician. He was honest as the day; a philosopher and wit; an admirable host and a good companion.—P. V. A.

Dr. WILLIAM JOHN FRAIN died at his home in Batley on Dec. 6 at the early age of 46, just two years after suffering an acute heart attack which severely limited his later activities. Dr. Frain came of a well-known Dundee family, and he graduated M.B., Ch.B. in 1931. He had worked in the public health service in Suffolk before coming to Yorkshire some ten years ago, and as medical officer of health of Pudsey, and later of Batley, he was an active member of the Yorkshire Branch of the Society of Medical Officers of Health and of the British Medical Association. He neither sought nor secured the limelight, but unostentatiously did much very useful work on behalf of the people of his town. Dr. Frain foresaw clearly the changing status of county district medical officers of health, a change which he considered was detrimental to the service as a whole. A bachelor, he nevertheless enjoyed a most comfortable home life with his sister. He was interested in children and young people, and they liked him. He was a keen churchman, and the large gathering at the memorial service, including the mayor and corporation of Batley and many doctors, was a genuine tribute from those who knew him best.—E. D. I.

Dr. WILLIAM JAMES BENNETT-JONES died at his home in Liverpool on Dec. 14 at the age of 75. A student of Edinburgh University, Dr. Bennett-Jones qualified in 1898, graduated M.B., Ch.B. a year later, and proceeded M.D. in 1903. Dr. Bennett-Jones was well known in Liverpool as an anaesthetist. He was a founder member of the Liverpool Society of Anaesthetists in 1930 and became its president in 1946. He was consulting anaesthetist to the Royal Liverpool United Hospital, and for many years senior honorary anaesthetist to the Royal Infirmary. Dr. Bennett-Jones was a fellow of the Association of Anaesthetists of Britain and Ireland and of the recently formed Faculty of Anaesthetists of the Royal College of Surgeons.

Mr. Robert Kennon writes: "B. J.," as he was affectionately called by his wide circle of friends, was a man of outstanding character, with deep religious feelings, and an exponent of family life and the full meaning of the home. Although a city dweller, he never lost his passionate love of Wales—its preachers and its poets, its language and its customs. A most charitable man, he gave his all in the service of his patients. No one was more accessible or more willing to respond to emergency calls at night, in spite of his advancing years. As an anaesthetist his services were appreciated by Mr. Thelwall Thomas, Sir Robert Jones, Sir Robert Kelly, and Mr. Thomas Guthrie—with whom he was associated in cottage and mansion, and in hospitals great and small. Others quickly recognized his reliability, his helpfulness and co-operation in difficult circumstances, and his continuing care for his patients during the period of recovery. He was a master in the art of administering open ether, in rendering it pleasant for the patients, in maintaining a clear air-way, and in using as little as possible of any drug consistent with a smooth operation. Indeed, it has often been said that more mesmerism than anaesthesia was given, and certainly the calm which fell upon his excitable countrymen as they counted slowly in Welsh was a revelation in the correct approach to anaesthesia. For thirty-six years he used endotracheal methods where necessary. Ever willing to learn, he continued to modernize his technique when, and only when, the new drug was beyond its experimental stages. He leaves a widow, two sons, and four daughters, to whom our deepest sympathy is extended.

Dr. EVAN WILLIAM MONGER HUBERT PHILLIPS died at his home in Port Talbot on Dec. 14 at the age of 64. Born at Newport, Pembrokeshire, Dr. Phillips was educated at Llandoverly College, Oxford University, and St. George's Hospital. He graduated B.M., B.Ch. in 1909, proceeding D.M. in 1921. He went on to take the F.R.C.S.Ed. and the M.Ch. in 1929, when he was an assistant in Port Talbot to the late Dr. J. H. Davies, whose partner he became. He had worked in this area for some forty years and had been prominently associated with Port Talbot General Hospital. Dr. Phillips was a magistrate and served on the county bench for many years, and he was also president of the local camera club.

Medico-Legal

LIBEL ACTIONS BY B.M.A. SETTLEMENT ANNOUNCED

In the King's Bench Division on Dec. 21 before Mr. Justice Hilbery the settlement was announced of two libel actions. The first was brought by the British Medical Association against Daily Mirror Newspapers, Limited, and the second by the British Medical Association against Dr. Santo Wayburn Jeger, Mr. Somerville Hastings, Dr. Louis Comyns, and Dr. Hyacinth Bernard Wenceslaus Morgan, who are all members of Parliament.¹

Mr. C. R. Havers, K.C., who appeared with Mr. H. C. Dickens for the Association, in announcing the settlement of the first action, said that in the issues of the *Daily Mirror* of Jan. 30 and Jan. 31, 1948, under the headings "Bevan challenges doctors on open ballot," and "Doctor M.P.s accuse B.M.A. leaders," the defendants referred to the ballot which was then about to take place. The British Medical Association took the view that passages in those two issues were so worded that it would be generally understood that the defendants were accusing the B.M.A. and its officials of so dishonestly conducting the plebiscite that, in spite of the pledge to the contrary given by the B.M.A., the individual voting of practitioners might be divulged, with possible serious consequences to the individuals. These allegations—if they had been intended—were of such a character that a body such as the B.M.A. was bound to refute them, and these proceedings accordingly followed.

Mr. Havers went on to say that he was happy to have it on the assurance of Mr. Milmo, on behalf of the *Daily Mirror* and its editor, which assurance Mr. Milmo would repeat in court, that the defendants never intended by the passages in question to impugn the honesty of the B.M.A. or any of its officers, and had never taken the view that the passages could be construed in that sense. As a token of good faith the defendants had agreed to pay a substantial sum, which the Association proposed to allocate to a medical charity, and to indemnify the Association against its costs. In these circumstances the plaintiffs were glad to accept the defendants' assurances and to bring the litigation to a close by asking his Lordship to allow the record to be withdrawn.

Mr. Helenus Milmo said that the *Daily Mirror* in these two issues of Jan. 30 and Jan. 31 had reported allegations that individual doctors might feel themselves intimidated because it was an open ballot. It was suggested that the B.M.A. would be in a position to gain a knowledge of how individual doctors voted and to use that knowledge to the detriment of those individuals who voted in favour of accepting the terms of the National Health Service. The *Daily Mirror*, having been given an opportunity to study the full arrangements for conducting the ballot, was satisfied that every precaution was successfully taken to ensure that how individual doctors voted would not be divulged. The *Daily Mirror* also wished to make it clear that at no time was it intended to question the integrity of the B.M.A., and as a token of good faith the *Daily Mirror* had agreed with the B.M.A. to pay a substantial sum to a medical charity nominated by them and to indemnify them against their costs.

B.M.A. v. Jeger and others

Announcing the settlement of the second libel action, Mr. Havers said that shortly after the plebiscite voting papers had been sent out to the members of the medical profession by the B.M.A. a letter signed by the four defendant doctors appeared in issues of the *Daily Telegraph*, the *Daily Mirror*, and the *Manchester Guardian*. This letter concerned, among other things, the methods proposed for ascertaining the views of the profession by means of the plebiscite. The B.M.A. took the view that the letter was so worded that it would be generally understood that the defendants were accusing the Association and its officials of so dishonestly conducting the plebiscite that, in spite of the Association's pledge to the contrary, the individual voting of practitioners might be divulged with possible serious consequences to the individuals. That allegation, if it had been

intended, would, of course, have been one which a body such as the British Medical Association was bound to refute. In this case also, however, the Association had the assurance given by Mr. Paget on behalf of the four defendant doctors that they never intended by their letter to impugn the honesty of the Association or of any of its officers, and had never taken the view that their letter could be construed in that sense. In these circumstances the Association was only too glad to accept that disclaimer and to proceed no farther with the action.

Mr. R. T. Paget, K.C., said that the letter to the newspapers which was the subject of these proceedings was never intended to impugn the honesty of the British Medical Association or of any of its officers and officials, and the defendants and their advisers had never taken the view that the letter could be construed in that sense. The defendants were glad to have this further opportunity of saying publicly that this was not and never had been their intention.

Mr. Justice Hilbery directed that the record in each action should be withdrawn.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The degree of M.A. has been conferred upon Joan M. Boissard, M.R.C.S., L.R.C.P., University Assistant Director of the Public Health Laboratory Service.

The following medical degrees were conferred on Dec. 11:

M B, B CHIR —*H. L. J. Wilson, *Mrs Camilla B. P. Bosanquet, Pamela F Davis.

* By proxy.

D. Russell Davis, M.D., M.R.C.P., has been appointed a Manager of the Pinsent-Darwin Fund for three years from Jan. 1.

An election to the Pinsent-Darwin Studentship in Mental Pathology will be made in March. The studentship is of the annual value of about £250 and is tenable for three years. The student must engage in original research into any problem having a bearing on mental defects, but may carry on educational or other work concurrently. Applications should be sent before Feb. 28 to the secretary, Pinsent-Darwin Studentship, Psychological Laboratory, Cambridge. Applicants should state their age and qualifications and the general nature of the research that they wish to undertake. No testimonials are required, but applicants should give the names of not more than three referees.

The following candidates have been approved at the examinations indicated:

FINAL M B —Part I (*Surgerv, Midwifery, and Gynaecology*) • K. P. Abel, C. A. Aitken, G. K. Barker, A. Bates, H. H. G. Bell, J. F. Boyle, B. I. Brown, P. Bryan Brown, D. Bulmer, J. F. C. Callow, C. C. Clapham, P. B. Corston, W. G. Dawson, G. H. Dunkerley, J. V. Earle, R. W. Fairhead, P. A. Freeman, A. C. Gibson, J. R. Gough, G. A. Gresham, B. M. Grimmett, E. C. B. Hall Craggs, G. F. Hargreaves, G. E. Heald, A. R. H. Hicks, R. N. T. Higgins, B. J. Hockey, J. W. Huddy, L. B. Hunt, I. P. James, M. J. Kehoe, D. S. Kerr, H. P. Kitner, D. G. A. Leggett, H. K. N. Lister, H. P. Lottenberg, C. McCance, A. McGregor, R. B. McGrigor, T. C. K. Marr, J. D. Marsh, M. Marshall, H. M. Michaelson, E. Monkhouse, A. D. Moore, W. P. L. Morrison, J. E. Naylor, J. H. Neame, D. H. Nurseman, B. W. Peckett, P. T. Perkins, S. T. H. H. Pilbeam, M. T. Pym, P. J. Roffey, C. A. Rogerson, R. A. Rowan, K. H. L. Scougall, I. H. Seppelt, M. J. Smith, J. F. Southill, J. Stevens, R. A. Struthers, T. J. Sullivan, M. K. Sykes, C. D. Thompson, P. W. Thompson, A. C. Townsend, T. H. H. Wade, D. P. Wagstaff, C. B. Walker, J. F. Watkins, E. J. Watson-Williams, D. Webb, E. K. Westlake, J. L. Whitby, M. Wilkinson, J. P. Williams, P. O. Williams, E. J. C. Wynne, J. G. O. W. Yerburch. Part II (*Principles and Practice of Physic, Pathology, and Pharmacology*) • R. D. Allen, P. J. Andrew, J. A. Balint, G. B. Barker, D. A. Beardsmore, G. P. Blanchard, T. B. Boulton, A. Brook, J. C. Burne, M. L. Cox, R. D. Cundall, P. G. R. Dench, J. R. Edsall, H. F. Flint, M. R. Gibson, J. G. Yerburch.

UNIVERSITY OF EDINBURGH

The University of Edinburgh gave a dinner on Dec. 10 in honour of the School of Medicine of the Royal Colleges, which has now been incorporated in the Medical Faculty of the University. Professor Sydney Smith, Acting Principal of the University, was in the chair, and there were also present the President of the Royal College of Physicians of Edinburgh, the Vice-President of the Royal College of Surgeons of Edinburgh, the Chairman of the Board of Governors of the School of Medicine of the Royal Colleges, other representatives of the Colleges, former members of the teaching staff of the Medical School, and members of the University Faculty of Medicine.

The Acting Principal proposed the toast of the School of Medicine of the Royal Colleges, which was replied to by Dr. W. D. D. Small, President of the Royal College of Physicians, Mr. J. M. Graham, Vice-President of the Royal College of Surgeons, and Mr. W. J. Stuart, Chairman of the Board of Governors of the School of Medicine. Dr. John Orr, formerly Dean of the School of Medicine, proposed the toast of the Faculty of Medicine. Professor T. J. Mackie, Acting Dean, replied on behalf of the Faculty. The Acting Principal, in proposing the toast of the School of Medicine, said that the school had been formally established only in 1895, but that its history went back to a much earlier time. The Guild of Barber Surgeons, which received its Charter in 1505, had been responsible for training its members, and from their foundation the Royal College of Physicians (1681) and the Royal College of Surgeons (1778) had interested themselves in the advancement and teaching of medicine and surgery. Before and after the formal establishment of the Faculty of Medicine within the University in 1726 classes were given by private individuals, who formed an extra-mural group of teachers more or less under the auspices of the Royal Colleges. This extra-mural school proved both a rival and a stimulus to teaching within the University. The brilliance of its teachers attracted students from many parts of the world, and, free from formalities, it was instrumental in introducing certain courses of study long before lectureships in the same subjects were provided within the University. Throughout the nineteenth century, also, many of the most distinguished professors in the University made their reputations as teachers in the extra-mural school. In later as in earlier years much of the renown of the Edinburgh Medical School was due to the work of the extra-mural school, and the University gladly acknowledged its debt to the School of Medicine of the Royal Colleges with which it had worked in friendly rivalry and co-operation for so long. Now, however (Professor Smith continued), circumstances had changed. With the progress of medical science and the increasing expense of providing medical teaching it was no longer possible to continue two teaching institutions in a city the size of Edinburgh, and the Colleges had shown wise statesmanship in deciding to merge their school with the Medical Faculty of the University. For the future, therefore, there would be one institution only for undergraduate teaching, and the Royal Colleges—relieved of their responsibilities at the undergraduate stage—would be free to concentrate on higher medical education through their interest in the Joint Board of Postgraduate Medical Studies. Concluding, the Acting Principal expressed the confident hope that with the combination of interests represented on that Board, and with the same co-operation between the University and the Colleges which had for so long been a feature of the Edinburgh School, the Postgraduate School would be no less renowned than had been its undergraduate predecessor.

At a Graduation Ceremony on Dec. 17 the following medical degrees were conferred:

M.D.—J. M. Alston, W. J. Matheson, Helen R. Neve
C.M.—E. A. Jack
Ph.D.—In the Faculty of Medicine: I. F. Sommerville
M.B., Ch.B.—Dores Baxter, H. Cameron, Isabel A. Cossar, J. Darnborough, J. C. Edie, W. D. Elliott, A. C. Ferguson, J. G. Fraser, G. B. Goodman, A. Gordon, P. F. Green, D. H. Haworth, S. P. A. Henderson, J. W. Herries, C. F. Hogg, J. T. Lamb, M. H. Lawrence, A. C. MacRae, Ann H. Miller, M. M. Milne, P. A. Moffat, Agnes C. D. Penman, T. R. Preston, M. L. Roden, B. H. Shiel, Catherine B. G. Sinclair, D. M. W. Smith, C. R. Walker, D. C. M. Wilcox.

Medical diplomas were granted as follows:

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE—S. R. A. Messiah
DIPLOMA IN MEDICAL RADIODIAGNOSIS—L. D. Keegan, L. D. Philp,
*P. St. G. Robinson
DIPLOMA IN MEDICAL RADIOLOGY—J. A. Caskey, *W. B. Dawson, *Mary
A. J. Douglas, *F. Riley
*Awarded medal for thesis. *Highly commended for thesis. *In absentia

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following candidates have been approved at the examinations indicated:

M.D.—E. Howitt, A. H. Isaacson, F. M. Lanigan-O'Keefe, J. B. Ryder, Sheila Sheehan
M.A.O.—J. D. Llewellyn-Jones
M.B.—D. W. Kyle, *Dorothy I. Ogden, *J. S. P. Lane, *Ivy P. Robinson, C. G. H. Charlton, M. H. Frithol, Peggy Moore, B. J. O'Reilly, G. N. Constable, Germaine H. Ross, F. W. Ennel, P. F. Eustace, W. A. McGaw, H. Parsons
B.Ch.—K. C. Mullen, T. M. W. Redman, E. M. Clein, Winifred D. Eadie, E. A. Jackson, W. H. Lefcovich, J. K. McCall, S. F. Shilliday, S. D. Boland, M. D. Bamber, Olivia M. Welch, J. Diamond
B.A.O.—J. P. B. Tuohy, H. Parsons, N. Furlong, Olivia M. Welch
*First-class honours. *Second-class honours.

The following medical degrees were conferred on Dec. 9:

M.D.—E. Howitt, Sheila Sheehan
M.A.O.—J. D. Llewellyn-Jones
M.B., B.Ch., B.A.O.—M. D. Bamber, S. D. Boland, E. M. Clein, G. N. Constable, J. Diamond, Winifred D. Eadie, P. F. Eustace, M. H. Frithol, E. A. Jackson, J. S. P. Lane, W. H. Leon, J. K. McCall, Peggy Moore, K. C. Mullen, Dorothy I. Ogden, T. M. W. Redman, Ivy P. Robinson, S. F. Shilliday, Olivia M. Welch.

UNIVERSITY OF DURHAM

The following candidates have satisfied the examiners at the examination indicated:

FINAL M.B., B.S.—G. L. Anderson, Anne R. Boon, P. G. Buck, Maureen T. Cunningham, June Dickson, Irene N. Dodd, Mildred C. Gardner, Sheila L. Harrison, Elizabeth J. Hunter, Alex P. M. Hurst, Ellen Huron, Hazel E. Jopling, R. N. C. Locky, J. McManis, J. G. Noble, Edith M. Robertson, D. Smith, J. D. R. Smith, Joan Stephens, A. E. Wright.

UNIVERSITY OF LONDON

The title of Professor of Pathology in the University has been conferred on Howard William Copland Vines, M.D., in respect of the post held by him at Charing Cross Hospital Medical School.

The title of Professor of Chemical Pathology in the University has been conferred on Jocelyn Patterson, Ph.D., M.Sc., in respect of the post held by him at Charing Cross Hospital Medical School.

A special University lecture in dentistry will be given by Professor G. Toverud, Director of the Department of Pedodontia in the Dental School, Oslo, in the Senate House of the University (entrance from Russell Square or Malet Street) on Wednesday, Jan. 12, at 5.30 p.m. His subject is "The Influence of General Health Supervision on the Frequency of Dental Caries in Groups of Norwegian Children." The lecture is addressed to students of the University and to others interested in the subject. Admission is free, without ticket.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

FINAL M.B., Ch.B.—Margaret Armitstead, Mary P. Armstrong, J. M. Bernstein, P. H. Bricewell, V. Broadhurst, R. B. Charrock, M. Cohen, J. L. Cohen, B. Gill, Doreen M. Giveter, Barbara Hall, B. Hendy, Muriel M. Hughes, H. McIntyre, C. A. Mays, K. Rawnsley, W. R. Riley, Beatrice E. Sleigh, R. V. Sykes, Ruth Tattersall, D. B. S. Taylor, G. Taylor, Helen L. S. Terrert, J. D. Torr, J. D. Villiers, J. M. Watt, H. L. Wray, Doreen Walsby, Pen J. H. G. Arnall, P. Feirgould, H. Holgate, J. R. Jaffe, B. Jones, K. Kitchell, H. A. Mitchell, Margot Nelken, J. A. Platt, C. W. M. Pratt, I. A. Strain, R. M. Thomson, C. A. Unsworth, J. M. Watt
DIPLOMA IN PSYCHOLOGICAL MEDICINE—Part II: E. Gossyrdi, H. F. Jervie

UNIVERSITY OF BRISTOL

The following candidates have been approved at the examinations indicated:

FINAL M.B., Ch.B.—R. J. Carey, Anne B. Cousins, Vera H. M. Dowling, D. N. Fitzgerald, Margaret Ford, Arne M. French, B. T. Hale, G. A. Hark, Kathleen J. Harrison (with distinction in public health), Jean A. Hiebert, Ursula Jones, A. H. Laxton, A. J. Lee, D. B. Peacock, Elizabeth Prescot-Thorpe, G. T. Salter, P. J. Sciller, Mario A. Wells, Group I (completing examination): G. D. Teague, A. S. Wallace, Group II (completing examination): Pamela L. C. Watson, Group II only: Justine Morgan, J. S. R. Old
DIPLOMA IN PSYCHOLOGICAL MEDICINE—Part II: M. A. X. Cochrane, V. G. Croity, W. A. Heaton-Ward.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The Faculty of Dental Surgery of the Royal College of Surgeons of England has arranged a series of lectures on anatomy, applied physiology, and pathology in their application to dental surgery and in dental histology, to be given at the College (Lincoln's Inn Fields, London, W.C.) at 5 p.m. and 6.15 p.m. on various dates beginning on Jan. 24 and ending on Feb. 18. The Faculty has also arranged a series of lectures on general, oral, and dental surgery to be given at the College at 5 p.m. and 6.15 p.m. on various dates beginning on Feb. 21 and ending on March 18. The fee for each course is £10 10s. (one lecture 10s.); Fellows and Members of the College and Fellows and Licentates in Dental Surgery of the College, £6 6s. (one lecture, 7s. 6d.). Admission cards may be obtained from the secretary of the Faculty at the above address.

At a meeting of the Council of the College held on Dec. 9, with Lord Webb-Johnson, President, in the chair, the award of Mackenzie Mackinnon Research Fellowships to Mr. W. J. Atkinson and Dr. C. F. Hawkins was reported. Dr. Horace Evans was elected a Hunterian Professor.

Diplomas of Fellowship were granted to the following successful candidates:

K. MacK. MacLeod, M. Ellis, E. Troensegaard-Hansen, A. B. Dempsey, E. P. Clarke, C. L. Clinton-Thomson, M. Ghik, C. T. A. Burgess, L. F. W. Salmon, C. R. Savage, J. Fenwick, D. H. Cammell, P. W. Hunt, K. P. S. Caldwell, J. L. Temple, R. N. Grant, J. S. A. Linton, M. F. Pilcher, D. P. B. Turner, D. A. Barley, B. L. N. Moxon, L. R. Cohen, A. C. Higgin, J. V. Morris, J. H. E. Verdon, G. B. R. Walker, R. D. Wilkins, H. M. Jones, E. H. M. Foxen, E. Haigh, J. G. Brockis, J. A. L. Davies, J. C. Fulford, O. Daniel, R. N. Kitchurst, J. F. R. Withycombe, G. W. Taylor, D. H. Randall, P. H. Hurrell, P. F. Jones, P. G. Large, B. W. T. Pender, J. M. Davis, J. Andrew, K. E. D. Shuttlesworth, R. J. Williams, R. L. B. Roberts, E. J. M. Weaver, D. L. B. Farley, M. J. Roger-Hall, G. J. Hadfield, J. A. MacDougall, A. Sinnatambhi, I. W. Ball, F. J. Damato, S. J. H. Muller, J. M. G. Kien, J. L. W. Wright, A. Yocum, P. F. Howden, G. C. Jennings, T. H. Wilson, P. L. Brunnen, E. M. Corvis, W. Gordon, G. H. Lewin, C. W. D. Lewis, A. K. Saka, Jean R. C. Burton-Brown, C. T. Collins, J. G. Gow, T. S. G. Gregory, J. D. Morgan, C. Parish, D. L. Shan, T. H. Tandy, C. B. R. Mann, H. G. Smith, M. Ahmad, H. M. Bradmore, J. W. F. Raine, S. Rajanayagam, J. B. Blacklay, B. H. Courtice, I. R. Kirk, K. R. Lothian, I. Monk, E. H. Paterson, D. A. Sandford, E. R. Shaw, P. Ahluwalia, R. D. A. Klesaria, K. D. Koshal, W. A. McAlpine, Marion J. Phillips, J. V. Ellis, P. G. Lai-g, D. Tooms.

Diplomas of Fellowship in Dental Surgery were granted to thirty-one candidates, including the following members of the medical profession: N. J. Ainsworth, G. A. Cowan, H. H. Kenshole, O. H. Wicksteed, J. W. Mansie, J. H. Hovell, M. P. Graham, and T. Cradock Henry.

Diplomas of Membership were granted to T. McKendrick and D. A. G. Williams.

Diplomas were granted jointly with the Royal College of Physicians of London as follows:

TROPICAL MEDICINE AND HYGIENE.—B. N. A. Beetles, M. A. Chowdhry, Joan E. Jermyrn.

MEDICAL RADIO-DIAGNOSIS.—J. W. Pierce.

ANAESTHETICS.—O. H. E. Bayles, O. D. Bhati, J. Bullough, L. Clement, Patricia F. de C. Coles, Elsa R. Cooper, J. A. L. Cooper, D. H. Couch, J. Davidson, Eleanor Davies-Jones, E. Fowler Ilse R. Hadelmayr-Kuhn, W. K. Jones, E. J. Leighton, Bertha A. McDougall, T. Wagner, J. M. Marchant, A. J. Merry, A. A. McC. Miller, L. E. Mossrop, G. P. Murtagh, D. K. W. Picken, W. L. Price, Silvia W. Pyddoke, L. W. Ritchie, F. L. Robertshaw, J. G. Robson, J. E. Schofield, W. R. Scott, Doris N. A. Smith, J. K. Sugden, J. H. Wakely, Pamela Westhead, D. Zuck.

INDUSTRIAL HEALTH.—J. W. Webb.

The following hospitals were recognized under the F.R.C.S. regulations: District Infirmary, Ashton-under-Lyne (resident surgical officer, until Dec. 31, 1950); Kent and Canterbury Hospital (additional recognition of ear, nose, and throat and ophthalmic house-surgeon and orthopaedic house-surgeon); the West Kent General Hospital (one house-surgeon); Boundary Park General Hospital, Oldham (resident surgical officer); the South Devon and East Cornwall Hospital, Plymouth (additional recognition of senior house officer (surgical) at Freedom Fields).

Medical Notes in Parliament

Capitation Fee

Sir WAVELL WAKEFIELD on Dec. 16 asked the amount of capitation fee doctors were receiving for their patients.

Mr. BEVAN said there was a fund of 18s. multiplied by 95% of the civil population. From this an agreed deduction was made for mileage payments, making the distributable fund about 17s. 5d. multiplied by 95% of the civil population. The actual payment per person on a doctor's list in any particular executive council's area varied with the proportion of the population who were on the lists of that area. He would not be able to say until after the end of the financial year what was the actual rate payable in each executive council's area. The representatives of the British Medical Association never expected that the rate would not be less than 18s. They knew that there would be certain agreed deductions from this. Sir WAVELL WAKEFIELD said the majority of doctors were suffering from this misapprehension.

Colonel STODDART-SCOTT asserted that the amount of money available for the doctors had been agreed on when it was thought 18,000 practitioners would come into the scheme. Now that 19,000 had come in, should not a larger amount of money be made available?

Mr. BEVAN said Colonel Stoddart-Scott's information was incorrect. The doctors were adequately represented and discussions were taking place between the Ministry of Health and representatives of the profession. He hoped members would await the result of those discussions before organizing a "single pressure lobby."

There were protests at this. Colonel ELLIOT asked Mr. Bevan to avoid making inflammatory and insulting speeches as he had done when the previous discussions were under way.

Mr. BEVAN said that the Opposition would probably seek an opportunity of discussing these matters. He reminded them that they could not seek to increase each item and expect the total to be low.

Amending Bill

Mr. BEVAN told Mr. COLLINS on Dec. 16 that he proposed to accept the recommendations of the Legal Committee on Medical Partnerships. So far as legislation was required, proposals would be made in the forthcoming Bill to amend the National Health Service Act. He hoped there would not be much delay in introducing this legislation.

Public and Private Prescribing

On Dec. 16 Sir WAVELL WAKEFIELD asked Mr. Bevan to indicate the administrative difficulties which prevented the disallowing of prescriptions prescribed at the public expense, but not conforming to required conditions, by doctors in the State service for private patients, while similar prescriptions by the same doctors for State patients could be disallowed.

Mr. BEVAN said a doctor in the Service who prescribed for patients treated under the Service substances which were afterwards found not to be drugs or not to be necessary for the proper treatment of the patient was subject to the disciplinary procedure provided in the regulations. The regulations did not, however, apply to private patients, for whom there was no prescribing at the public expense.

Replying later to Mr. ASTOR, Mr. BEVAN said he was unaware of any general abuse of medical prescriptions under the Health Service. There were a number of individual cases. Disciplinary procedure was provided to deal with them. He wanted it to be firmly and promptly used.

Cost of N.H.S.

Answering Colonel STODDART-SCOTT on Dec. 16, Mr. BEVAN recorded that the total amounts paid out of public funds since July 5 and up to Nov. 30, 1948, in respect of hospital services, general medical services, pharmaceutical services, general dental services, and ophthalmic services were as follows:

	£
Hospital services	58,000,000
General medical services	7,922,994
Pharmaceutical services	5,438,709
General dental services	5,541,658
Ophthalmic services	4,047,568

He added that the total liability incurred in that period could not be stated.

Statements of probable expenditure for the financial year 1948-9 had recently been received from all regional hospital boards and were being examined. None had yet been approved. All regional hospital boards had also submitted estimates for the financial year 1949-50. Gross expenditure as shown in these estimates as received was £157,680,000; of this, £10,236,000 represented capital expenditure. Income was given as £9,021,000.

Artificial Insemination

On Dec. 16 Mr. ERIC FLETCHER asked the Minister of Health what instructions he proposed to issue as to the entries to be made in registering births resulting from human artificial insemination A.I.(D.).

Mr. BEVAN said no fresh instructions were necessary. Registrars already had instructions to ask every birth informant for the name of the child's father. If the informant could not give this information the columns of the birth entry containing particulars of the father were to be left blank. So far as he knew, this procedure had no bearing on the legitimacy of the child.

Cardiff Doctors

Mr. BEVAN stated on Dec. 16 that fourteen doctors in Cardiff each had more than 4,000 registered patients. The highest number of people registered with one doctor in Cardiff was 7,190. This doctor practised in a partnership employing two assistants. Seventeen Cardiff doctors had applied for the basic salary of £300.

Mr. GEORGE THOMAS asked whether Mr. Bevan knew of the difficulty caused in Grangetown, Cardiff, by four doctors operating from one small surgery, having closed their other surgery when the National Health Service started, and whether, in view of the daily queue caused, he would ensure that another surgery was made available.

Mr. BEVAN replied that a doctor was required under the regulations to provide proper and sufficient surgery and waiting-room accommodation for his patients. This case had been considered by the Cardiff Executive Council, who had drawn the practitioners' attention to the need for full compliance with the terms of these regulations.

Dental Estimates

Sir HUGH LUCAS-TOOTH on Dec. 16 inquired what was the total value of estimates approved by the Dental Estimate Board in Eastbourne for each of the months July, August, September, October, and November.

Mr. BEVAN replied that the total values of the approved estimates included in schedules sent for payment to executive councils were:

	£	s.	d.
July	51,253	3	0
August	303,677	2	3
September	997,125	7	9
October	1,882,608	13	3
November	2,461,134	17	2
Total	5,695,799	3	5

He added that not all these schedules would have reached executive councils in time for payment to have been made to the dentists by Nov. 30.

PRESSURE DRESSING FOR A SCALD

AUGUST 22nd, 1947. Scalded at work. Next day attended hospital with a large blister of inner aspect R. ankle (Fig. 1)

Treatment. Scalded area dressed with Jelonet (tulle gras), Viscopaste bandage applied from toes to knee. Pressure pad of cotton-wool applied over scalded area. The whole leg firmly bandaged with Elastocrepe, with especially firm pressure over the scalded area (Fig. 2)

Fig. 2

7th October, 1947. When bandages were removed, wound soundly healed. (Fig. 3).

Comment. Firm pressure dressing afforded *immediate* comfort, permitting ambulatory treatment and continuation at work

These details and illustrations are of an actual case. T. J. Smith & Nephew, Ltd., of Hull, manufacturers of Elastoplast, Elastocrepe, Jelonet and Viscopaste, publish this instance—typical of many—in which their products have been used with success.

relief...

CONSCIOUS or unconscious fear of an attack often shadows the mind of the asthmatic. the knowledge that he has 'Franol' to forestall or relieve such attacks can dispel this shadow and restore confidence

'Franol' is a potent combination of ephedrine (to relieve bronchial spasm), theophylline (to dilate the bronchioles) and 'Luminal' (to mitigate apprehension)

At the first warning of an attack, two tablets of 'Franol' will often bring relief. Taken regularly, 'Franol' will bring an all round improvement in the general condition

Medical literature supplied upon request

Tablets in tube of 30 bottles of 100, 500, 1,000

ANAHÆMIN B.D.H.

In Neurological Complications of Pernicious Anæmia

The hæmopoietic factor as presented in Anahæmin B.D.H. is essential for the prevention of subacute combined degeneration of the cord. Other substances, such as folic acid, will produce an adequate hæmatological response but allow neurological degeneration to appear and to progress unchecked. Potent liver preparations must be regarded as essential for the satisfactory treatment of pernicious anæmia.

Each batch of Anahæmin B.D.H. is clinically tested before issue.

THE BRITISH DRUG HOUSES LTD LONDON N1

Anah B 110

Are vitamins enough?

Obviously, no. The rationale of giving vitamin D, for example, alone, when calcium intake is limited, would be difficult indeed to justify. Similar considerations may apply to other factors, as for example iron and vitamin C.

All these, and other analogous considerations, have been borne in mind in the design of Complevite, which provides, in rational dosage, vitamins and minerals commonly needed as additions to the dietary intake.

Complevite is thus the prescription of choice, both from the point of view of convenience and of economy. *Prescription of Complevite is less expensive than prescription of the individual factors.*

COMPLEVITE

The Vitamin and Mineral Supplement

The recommended adult daily dose provides:—

vitamin A	2,000 i.u.	vitamin C	20 mg.	iodine	} not less than 10 p.p.m. each
vitamin D	300 i.u.	calc. phosph.	480 mg.	manganese	
vitamin B ₁	0.6 mg.	ferr. sulph. exsic.	204 mg.	copper	

A clinical sample gladly sent on request to Medical Dept. 49.A.

MAGNA EST VIS CONSUECUDINIS (CICERO)

The power of habit is great—and is undoubtedly the basis for satisfactory bowel movement in the normal individual. During illness and convalescence or due to the tempo of civilisation habit-time of bowel movement is often lost and constipation follows.

Once lost, this habit-time is not easy to regain, but 'PETROLAGAR' will do much to help in its recovery. 'PETROLAGAR' impregnates the faeces, softens hard, dry stools and achieves a comfortable bowel movement without griping.

PETROLAGAR

* Measles and whooping cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county) will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county) and Northern Ireland.

§ The number of deaths from poliomyelitis and poliomyelitis for England and Wales, London (administrative county) are combined.

¶ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Influenza Epidemic in Italy

The current influenza epidemic in Italy, although widespread, is said to be a relatively mild form of the disease. According to the World Health Organization's Division of Epidemiology, by mid December the disease was continuing on an epidemic scale in Rome and was widespread both in the central and southern provinces of the mainland and also in Sardinia. More recent information indicates that the infection has since spread to the northern provinces.

It appears that the influenza has run a mild clinical course in all affected regions. It is characterized by high fever which persists for two or three days but then diminishes progressively to normal. Attacks usually last four to five days in all. Fatal lung complications have been observed only among the aged. In this connexion it is noted that the number of deaths from bronchopneumonia does not exceed the seasonal average. Laboratory studies at Sassari in Sardinia, have identified the strain as virus B.

Sickness and Diarrhoea at Chatham

An outbreak of vomiting affecting 58 children but no member of the staff occurred at a Chatham secondary school on Nov. 18, 1948. 20 of the affected children had diarrhoea and sickness. Most of the children were sick between 1.30 and 3.30 p.m., but 10 reported that sickness began at home after 4 p.m. All the affected children were able to go home at 4 p.m., and with one exception all returned to school the following day. About half the children had school milk (pasteurized) in the morning, and 53 of the 58 had the school dinner of cottage pie with greens, and macaroni pudding with jam sauce, served at 12.15 p.m. The 5 who did not have their dinner in school were in a classroom where about a dozen children were sick.

The central kitchen where the dinner was cooked is well equipped, and the hygiene of the premises, equipment, and staff is good. Two of the staff had colds. None had skin lesions. On the day in question 955 dinners were distributed in the cooking containers to six different schools. In the school where the trouble occurred 313 meals were consumed by pupils and staff. No other school was affected. The children do not sit in class groups for dinner. No particular class was attacked. It is not known if the affected children were served from the same containers or by the same person. The minced meat portion of the cottage pie had been precooked on the previous day and stored overnight in the refrigerator on large enamel trays. It was reheated with a covering of mashed potato in the oven the following morning. The remainder of the food was prepared and cooked just before being distributed.

Food containers and crockery were washed immediately after dinner, and no food was available for bacteriological examination. Swabs were taken from the throat, nose, and hands of the kitchen staff, and from 12 *Staphylococcus pyogenes* was recovered on culture, in two cases from all three sites. Two specimens of vomit were submitted for examination and *Staphylococcus pyogenes* isolated. None of the cultures isolated from the food handlers was identical with those obtained from the two vomits. The possibility of metallic poisoning from the food containers was excluded. A complete bacteriological investigation was not possible, and the limited inquiry does not support the preliminary assumption that the symptoms were due to the presence of a staphylococcal enterotoxin in a small proportion of the total food consumed.

Discussion of Table

In England and Wales an increase was recorded in the notifications of measles 1 532 and acute pneumonia 130 decreases were reported for scarlet fever 117, whooping cough 40, and acute poliomyelitis 16.

Large increases in the incidence of measles occurred in Lancashire 514, Yorkshire West Riding 352, Essex 99, Lincolnshire 95, and Middlesex 85. There was a decline of 48 in the notifications of scarlet fever in Yorkshire West Riding.

There were decreases in the incidence of whooping-cough in Yorkshire West Riding 44 and Durham 32, with a rise of 46 in London. A small rise occurred in the incidence of acute pneumonia in every region except in the south-eastern counties, where no change occurred.

An outbreak of dysentery affecting 8 persons was notified from Cheshire, Wirral R.D., the only other large return was Lancashire 12. Notifications of acute poliomyelitis were the lowest since the middle of July, the latest returns during the week were London 4, Yorkshire West Riding 4, Middlesex 3, and Nottinghamshire 3.

In Scotland increases were recorded in the number of notifications of acute primary pneumonia 60 and whooping-cough 27.

There was a decrease of 18 in the notifications of measles. Notifications of diphtheria fell from 21 to 10 in Glasgow, but this was compensated for by a rise of 12 in the remainder of the western area.

In *Eire* a fall was reported in the notifications of measles 39 and scarlet fever 24, while a rise of 16 was recorded for whooping-cough.

In *Northern Ireland* a decrease of 9 in the notifications of scarlet fever and an increase of 5 for diphtheria were the chief changes in the trends of infectious diseases.

Week Ending December 18

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,426, whooping-cough 2,471, diphtheria 124, measles 9,800, acute pneumonia 1,082, cerebrospinal fever 35, acute poliomyelitis 28, dysentery 54, paratyphoid 1, and typhoid 7.

Medical News

Chadwick Medals

The Chadwick Trust recently awarded Chadwick Medals to the nominees of nine provincial universities where sanitary science is taught, or where the Diploma of Public Health is given. The inscription on each medal was as follows: "Chadwick Medal for excellence in the study of Hygiene and of the Sanitary Idea." The names of the nine recipients are as follows, with the universities indicated in parentheses: C. R. Lowe, M.B., Ch.B., D.P.H. (Birmingham); William Nicol, M.B., Ch.B., D.P.H. (Bristol); G. W. Knight, M.B., Ch.B., D.P.H. (Leeds); H. O. M. Bryant, M.B., Ch.B. (Liverpool); D. G. Crawshaw, M.B., Ch.B., D.P.H. (Manchester); William Watt, M.B., Ch.B., D.P.H. (Aberdeen); Gerald O. Mayne, M.B., Ch.B., D.P.H. (Edinburgh); Angus N. MacPhail, M.B., Ch.B., D.P.H. (Glasgow); Sheena M. Allardice, M.B., Ch.B., D.P.H. (St. Andrews).

London School of Hygiene and Tropical Medicine

The Langley Memorial Prize, which is open to competition among officers, past and present, of the Colonial Medical Service who are serving, or who have served, in West Africa, has been awarded to Dr. D. G. Fitzgerald Moore for his paper entitled "Nutritional Eye Disease and Effects of Nutritional Retrobulbar Neuritis."

University Grants Committee

The following medical men are among the members of the University Grants Committee, which has been reconstituted: Professor E. D. Adrian, O.M., F.R.S., Professor G. W. Pickering, and Professor J. C. Spence.

Dr. S. L. Simpson

Dr. S. Leonard Simpson has been elected an Honorary Corresponding Member of the French Society of Endocrinology.

"Agene" Process Prohibited in U.S.A.

The use of nitrogen trichloride to improve and bleach flour (the "agene" process) is to cease in the U.S.A. from Aug. 1 as the result of an inquiry set up under the Food and Drug Administration. Sir Edward Mellanby, F.R.S., first showed that agenzized flour causes hysteria in dogs; his paper appeared in 1946 in this *Journal* (Dec. 14, p. 885). Chlorine dioxide is to be allowed instead of nitrogen trichloride.

Wills

Colonel Sir Harry Edwin Bruce Bruce-Porter, K.B.E., C.M.G., left £42,618. Mr. Cyril Alban Raison, of Birmingham, left £29,557 and bequeathed £2,000 to the Faculty of Medicine of the University of Birmingham to endow "The Cyril Raison Prize" in surgical diseases in children. Dr. Thomas Gwynne Matland, late medical superintendent, Cunard White Star Line, left £3,611.

COMING EVENTS

Legislation and the Family

A conference on "The New Social Legislation and the Family" will be held at the Conway Hall, Red Lion Square, London, W.C.1, on Jan. 20 and 21, 1949, by the British Social Hygiene Council and the Town and Country Planning Association. It is intended mainly for representatives of local authorities, but social workers and others may be interested. Information may be obtained from the British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1.

Society of Anaesthetists of South Wales

A Society of Anaesthetists of South Wales is in the process of formation and a meeting with this end in view will be held at Cardiff Royal Infirmary on Wednesday, Jan. 12, 1949, at 8 p.m. All those whose main interest is in anaesthesia are invited to attend the meeting.

Lecture-demonstrations

A series of lecture-demonstrations on psychiatry and neurology will be held in the large lecture theatre of St. George's Hospital Medical School, Hyde Park Corner, London, S.W., on Thursdays at 4.30 p.m., from Jan. 6 to March 17. They are open, without fee, to all postgraduates and senior medical students.

SOCIETIES AND LECTURES

Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Jan. 4, 5 p.m. "*Zoonoses (Parasitic Infections)*," by Dr. M. Sydney Thomson.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Jan. 4, 11 a.m. "*Some Aspects of Leucorrhoea*," by Dr. W. N. Mascall.

Wednesday

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Jan. 5, 11 a.m. "*Gonorrhoea in the Female*," by Dr. W. N. Mascall.

LONDON COUNTY MEDICAL SOCIETY.—At Furnivall House, Chelmondeley Road, London, N., Jan. 5, 4.30 p.m. Annual general meeting. Address by the retiring president, Mr. J. R. M. Whigham.

SOCIETY OF CHEMICAL INDUSTRY: NUTRITION PANEL OF THE FOOD GROUP.—At Gas Industry House, 1, Grosvenor Place, London, S.W., Jan. 5, 6.30 p.m. "*The Sausage as Food*," discussion to be opened by Mr. H. P. Blunt, Mr. Osman Jones, Mr. M. G. Read, and Dr. Magnus Pyke, Ph.D.

Thursday

FACULTY OF HOMOEOPATHY.—At Royal London Homoeopathic Hospital, Great Ormond Street, London, W.C., Jan. 6, 5 p.m. "*Head Hunters in Great Ormond Street*," by Drs. W. Lees Templeton and Charles O. Kennedy.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Jan. 6, 5 p.m. "*Cutaneous Tuberculosis*," by Dr. G. B. Dowling.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Jan. 6, 11 a.m. "*Local Complications of Gonorrhoea in the Female*," by Dr. W. N. Mascall.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—At Large Lecture Theatre, Jan. 6, 4.30 p.m. Lecture-demonstration: Psychiatry.

Friday

MAIDA VALE HOSPITAL MEDICAL SCHOOL, Maida Vale, London, W.—Jan. 7, 5 p.m. Case demonstration by Dr. D. McAlpine.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Apley.—On Dec. 16, 1948, at Woking Maternity Home, to Janie, wife of A. G. Apley, F.R.C.S., West Lodge, West Byfleet, a son.

Barry.—On Dec. 15, 1948, at March, Wilmslow, to Monica (née Craig), wife of C. T. Barry, M.D., D.A., a third son.

Ffrench.—On Nov. 28, 1948, to Marjory and Geoffrey Ffrench, of Pleasant Street, Woodside, Halifax County, Nova Scotia, a daughter.

Parker.—On Dec. 15, 1948, to Kathleen (née Hewlett Johnson), wife of Geoffrey Parker, D.S.O., F.R.C.S., a son—Nicholas James.

Watson.—On Dec. 13, 1948, at the County Hospital, Bangor, to Megan (née Wynne Jones), wife of Claud C. M. Watson, M.B., Ch.B. Ed., a son—David.

DEATHS

Bennett.—On Dec. 21, 1948, at Mildenhall, William Fay Bennett, M.R.C.S., of Barrow, Suffolk.

Bennett-Jones.—On Dec. 14, 1948, at 5, Gambier Terrace, Liverpool, William James Bennett-Jones, M.D., M.R.C.S., F.F.A., aged 75.

Bhat.—Recently, at Karkala, India, Kasargod Somanath Bhat, M.R.C.S., L.R.C.P., aged 63.

Bunting.—On Dec. 15, 1948, William Hartley Bunting, M.D., F.R.C.S. Ed., of Middleton Cottage, Salwarpe, Droitwich, aged 80.

Colledge.—On Dec. 19, 1948, at 2, Upper Wimpole Street, London, W., Lionel Colledge, F.R.C.S.

Jamieson.—On Dec. 16, 1948, at Thorne Bank, Great Eccleston, Lancs, Alexander Brown Jamieson, M.B., Ch.B. Ed.

Logie.—On Dec. 20, 1948, at 15, Craigholm Crescent, Burntisland, Fife, John Moffat Logie, M.B., Ch.B. Ed.

Morrison.—On Dec. 17, 1948, at 19, Cromer Road, North Walsham, Norfolk, Henry Morrison, M.D., aged 54.

Sutton.—On Dec. 20, 1948, at Guildford, David Carlyle Sutton, M.D. Ed.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest

Leucorrhoea

Q.—What is the modern treatment of leucorrhoea, excluding cases due to organic disease and to bacterial infections?

A.—The question rather implies that the term "leucorrhoea" should be reserved for a discharge which is normal in composition but increased in amount. This view coincides with that of the writer, but is not shared by all. If this definition be accepted, then before treatment is instituted it is important to try to assess the amount of discharge. Many women, through ignorance or over-anxiety, may regard the normal as pathological. The activity of the glands lining the genital tract (those in the cervix being the most important) probably varies in different individuals, and sometimes even a rather free secretion is not really abnormal. The vaginal discharge is also physiologically increased premenstrually, during pregnancy, and sometimes about the time of puberty. Ovarian function can also influence the discharge, as is evidenced by the free mucoid secretion from the cervix about the time of ovulation. No treatment other than reassurance and education is necessary in any of the above circumstances.

Increased vascularity or congestion of the pelvic organs acting either directly on the glands or indirectly by way of an ovarian disturbance, appears to be an important factor in leucorrhoea. By this mechanism many causes—working in hot atmospheres, standing for long hours, sedentary occupation, masturbation, unsatisfied sex urge, chronic constipation, etc.—may operate. Any form of chronic ill-health, and anxiety alone, can also cause leucorrhoea. Treatment depends on the cause, but if this is not obvious the measures adopted should be of a general rather than of a local character—regular physical exercise, daily cold baths, saline aperients, reassurance, etc. Astringent douches are rarely used nowadays. Finally, it should be kept in mind that the excessive discharge may be due to an increased amount of glandular tissue in the cervix—an adenomatous state. In this condition erosion of the cervix (a lesion which is not necessarily a response to infection) is often present, and is best treated by cautery or surgical diathermy.

Penicillin and Vaccinia Virus

Q.—(a) Has the use of penicillin in reducing the bacterial contamination of vaccine lymph (calf lymph) been investigated? If so, please give references. (b) May I have the names of institutions, if any, which are preparing anti-smallpox vaccine by the egg-culture technique for mass use?

A.—(a) A number of investigations have been carried out on the effects of penicillin in reducing bacterial contamination of vaccine lymph (see Morin, J., and Turcotte, H., *Canad J Res. Sect. E*, 1946, 24, 149). Similar studies have been made in France (Sevin, A., Bossut, J., D'Halluin, G., and Chenet, C., *Ann. Inst. Pasteur, Lille*, 1948, 1, 209). In Russia the use of Soviet gramicidin has been recommended (Marchenko, G. F., and Raphman, E. Z., *J. Microbiol.*, Moscow, 1946, No 3, p. 16), and in South America tyrothricin has been employed (Miranda, C., *Hospital, Rio de J.*, 1946, 30, 803). There are certain points to be remembered. Whereas pure penicillin has no action on vaccinia virus, impure penicillin may destroy it (Gohar, M. A., and Bashatli, A., *J. trop. Med Hyg.*, 1946, 49, 115). Penicillin does not necessarily destroy all contaminants. *Pseudomonas aeruginosa* (Ps. pyocyanea) may be quite resistant. D. H. Ducor (*Publ. Hlth Rep. Wash.*, 1947, 62, 565) used a quaternary ammonium compound derived from coconut oil and said to be a mixture of high molecular weight alkyl-dimethyl-benzyl ammonium chlorides: the preparation is known commercially as "roccal."

(b) Investigations are being carried out in Great Britain on vaccinia grown in eggs at the Lister Institute, Elstree, Herts, and at various research centres in America. Egg-culture vaccine is still in the experimental stage and none is yet being issued for mass use.

Cholesteatoma

Q.—What are the pathology and treatment of a cholesteatoma?

A.—A cholesteatoma is a rare tumour occasionally found arising from the meninges, commonly at the base of the brain. It is usually well encapsulated and composed of cells of epithelial type containing crystals of cholesterol and arranged in whorls. It is probably of epidermoid origin and of a teratomatous nature. It is innocent. The treatment is surgical.

Trichorrhexis Nodosa

Q.—What is the cause of splitting of the ends of scalp hair? A female aged 19, otherwise healthy, has suffered from this complaint for four years. Is there a remedy?

A.—The splitting of the ends of scalp hair (trichorrhexis nodosa) is not a disease but a common condition. It is due to excessive dryness of the hair, such as is caused by too frequent washing, especially with alkalis, some powder shampoos, and spirit lotions without oil or glycerin to counteract their drying effect. Trauma by too hard brushing and rubbing, and from certain types of brushes and sharp-pointed combs, is also a common cause of the breaking of the hair shafts.

Bromidrosis

Q.—Can you suggest a successful treatment for severe bromidrosis other than a daily bath and change of underwear? What is the cause of this condition?

A.—The cause is probably endocrine, but gastro-intestinal function may need consideration. The age, sex, and health of the patient have a bearing on the question of treatment. Small doses of stilboestrol are sometimes helpful. Bicarbonate of soda is a good deodorant used in a bath or as a powder, or, if the condition is localized, as a 25% paste. Sodium hexametaphosphate is similarly of value in local treatment used in the same manner. (See also "Any Questions?" Feb 15, 1947 p. 281, and March 15, 1947, p. 366.)

Trigeminal Neuralgia

Q.—What is the best medical treatment for trigeminal neuralgia? The preliminary communication on "cuprelone" seems promising. Is this drug obtainable? If so, are any special precautions necessary in its use?

A.—Treating cases of trigeminal neuralgia with large doses of vitamin B₁ (aneurin or thiamin), Borsook (*J. Amer. med. Ass.*, 1940, 114, 1421) described marked improvement in 37 out of 58 patients and some improvement in 55 out of 58. He gave 10 mg daily by intravenous injection, together with a diet rich in vitamin B₁. It is probably sufficient to give vitamin B₁ by mouth, but in large doses such as 25 mg four times a day. If drugs are to be used, "cuprelone" can be tried. The author of the *Lancet* article (Oct. 23, 1948) says that the toxic effects it produces are negligible, but it is probably too early to say how severe they may be in certain sensitive cases. Since it is a derivative of allylthiourea, it may inhibit the thyroid in some patients. Other drugs which have a good effect are "trilene" (trichlorethylene) and tinctura gelsemii (10 to 15 minims: 0.6 to 0.9 ml thrice daily).

Bleeding Gums

Q.—What is the treatment of bleeding gums? I have in mind a woman aged 25, 3-para, with no infection whatsoever in the mouth and whose general health is excellent. A thorough trial of vitamin C, toothpicks, and painting with chromic acid and hydrogen peroxide has led to no improvement, and the patient is afraid of developing pyorrhoea.

A.—Bleeding gums may be due to numerous causes, both general and local. Clearly, before suggesting any form of treatment it is of the utmost importance to ascertain the cause of the bleeding: thus, vitamin deficiencies (such as scurvy), blood disorders (such as leukaemias), etc., are often associated with spongy bleeding gums. Investigation of the patient's blood is therefore of importance where no local cause is obvious. The most common cause of bleeding from the gums is a gingivitis, which may be mild or severe in extent. This is particularly the case with the rather oedematous type, where the interdental

bleeding. Occasionally it is found that in comparatively normal patients with healthy gums bleeding is caused by the excessive and over-zealous use of hard toothbrushes.

Liver Injections in Arthritis

Q.—(a) *Is there any evidence to support the giving of liver injections in the anaemia associated with rheumatic and other arthritic conditions? I should be glad to know if there has been any work on this subject recently.* (b) *What is the percentage of cases of fibrositis which have a "gouty" pathology, and what is the likelihood of these cases being relieved by either cinchophen or colchicum?*

A.—(a) There is no conclusive evidence to indicate that liver injections would influence the anaemia associated with arthritis, but a liver extract would supply vitamin B as well as other substances, and, as so little is known of the pathology of rheumatoid disease, it might be justifiable to try it and watch the effect. In such cases the writer has used a special form orally with good effect on the general condition, but is not aware of any recent work on this aspect.

(b) It is impossible to give a percentage of cases of fibrositis which have a gouty pathology. The only plan would be to test for the blood uric acid content; if this is above normal it might be regarded as evidence of a possible gouty cause in the absence of trauma or any abnormality revealed by a thorough x-ray examination. Unless the blood uric acid content is increased there is no indication for either colchicum or cinchophen, and much to be said against using either, though the latter might have a temporary analgesic effect; aspirin would be far preferable and, as the salicylates tend to lower the blood uric acid content, more effective.

Rh Factor and Pregnancy

Q.—*In view of the baffling complexity of recently published work on the Rh factor, I should like to know what action should be taken on receipt of a report of "Rh-negative, anti-Rh agglutinins present" on the blood of a woman five or six months pregnant. Is there any danger to the foetus from this in a first pregnancy?*

A.—On receipt of a report that a pregnant woman is Rh-negative and has Rh antibodies in her blood it is advisable to arrange for the confinement to take place in hospital, and to make preparations to transfuse the infant with Rh-negative blood without delay if its cells are found to be sensitized to Coombs's test. Antibodies are unlikely to be present at five or six months in a first pregnancy, and there is little or no danger to the first foetus from this cause, unless in twin pregnancy. In subsequent pregnancies, if a woman is found to be Rh-negative but without evidence of antibodies, it is advisable to be prepared to treat the child if found to be affected, but treatment should not be given without proof of haemolytic disease, because many Rh-negative women fail to become sensitized even after several pregnancies (see *B.M.J.*, 1946, 2, 641, for details). There is no justification for the interruption of pregnancy unless on grounds that the mother's health is adversely affected—for example, by toxæmia.

Ultra-violet Light and Pulmonary Tuberculosis

Q.—*Is it not possible that the well-known effect of ultra-violet light in stimulating the activity of pulmonary tuberculosis could be made use of by giving ultra-violet light treatment at the same time as bacteriostatic drugs—p-aminosalicylic acid and streptomycin—on the assumption that the increased activity of the organism would increase its metabolic requirements, and that thereby the intake of these drugs by the micro-organism would be greater?*

A.—No. Ultra-violet light can have no possible direct action on tubercle bacilli in the lung. The effect of ultra-violet light or excessive exposure to sunlight on pulmonary tuberculosis is believed to be to cause reflex pulmonary congestion, with a consequently increased liability to haemoptysis; the flooding of part of the bronchial tree with blood containing tubercle bacilli is then liable to bring about extension of the disease.

NOTES AND COMMENTS

Leukoplakia and Kraurosis Vulvae.—Dr. ELIZABETH HUNT (London, W.) writes: In "Any Questions?" (Dec. 4, p. 1005) the writer states that kraurosis vulvae "might be considered as an exaggeration of normal senile atrophy, and for all practical purposes it occurs only after suppression of ovarian activity." How can these assumptions be reconciled with the fact that the women described by Breisky (the author of this term), who were suffering from this condition, were all within the reproductive period of life and all apparently with full ovarian activity? I have myself seen many cases of stenosis of the ostium vaginae (i.e., kraurosis vulvae) in younger women whose ovarian functions seemed to be normal. Some of these cases had been diagnosed as "senile atrophy." It would be of interest to know what exactly is meant by "normal senile atrophy." Does this occur at one site only on the skin—namely, the vulva? With reference to leukoplakia vulvae it is my experience that this term is used very loosely for a variety of widely differing skin affections which may present a whitish appearance. These conditions are often prolonged in duration despite medication; none is precancerous. Cancer, when it does occur in association, is found on the internal surfaces of the vulva only. Can excision of skin around the vulva be therefore justified, as the writer suggests?

Corrections

In the review of *Textbook of the Rheumatic Diseases*, edited by W. S. C. Copeman (Dec. 25, 1948, p. 1108), there is an inaccuracy in the second paragraph. This arose through a misreading of the chapter on clinical pathology contributed by Dr. M. J. Gibson. A correction, which unfortunately arrived too late for inclusion in last week's issue, makes this part of Dr. Kenneth Stone's review read as follows: "Dr. M. J. Gibson contributes a chapter on clinical pathology. His discussion of the blood uric acid is not very clear. He states that plasma uric acid is higher than whole-blood uric acid by 1.0 to 2.0 mg., the normal being up to 6 mg. per 100 ml.; a plasma estimation is more reliable, he says, because of variations in the red cell volume. But there is no accurate method of measuring the uric acid in a protein-free filtrate of the plasma, and 4 mg. per 100 ml. has long been accepted as the upper limit of the normal range. Comparatively recent work suggests 6 mg. as a more accurate dividing line between the non-gouty and the gouty; but further confirmation of this is desirable."

Dr. G. MACD. CAMPBELL (Tylorstown, Glam) has pointed out a mistake in our report (Dec. 11, 1948, p. 1031) of the speech by Mr. John Edwards at the opening of the Public Health and Municipal Engineering Congress. According to the official report of the speech issued by the Ministry of Health Mr. Edwards said that under the National Health Service prescriptions were being dispensed at the rate of 140,000 a year. The figure should have been 140,000,000 prescriptions a year.

Dr. DOROTHY M. JAMES, Medical Officer of Health (Standish-with-Langtree Urban District Council) writes: In the "Epidemiological Notes" (Dec. 18, 1948, p. 1087) I notice that in the discussion of the table for the week ending Nov. 27, 1948, you refer to a local outbreak—7 cases of diphtheria—in the urban district of Standish-with-Langtree. This is incorrect. There were no cases of diphtheria in this district during that period, but 7 cases of measles were returned. I have taken the matter up with the Registrar-General.

In a reference to the Todd insecticide fog-applicator ("Any Questions?" Dec. 11, 1948, p. 1048) it was stated that the T.I.F.A., "so far as we are aware, is not manufactured here." We are informed by the Lister-Todd Engineering Corporation, Ltd., of Imperial House, 15/19, Kingsway, London, W.C.2, that the machine is being produced in this country.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JANUARY 1 1949

THE SECRETARY REPORTS

WHAT NEXT?

Terms and conditions of service, including remuneration, have dominated the medico-political picture in recent months. It seems a long time since the issues of the day were the Minister's power to introduce a whole-time salaried service, the universal basic salary, direction, the ownership of goodwill, the experimental health centre, appeals to the Courts, and freedom to publish. It seems an age since Mr. Ernest Brown put forward proposals for a whole-time salaried service, since the right of the Central Health Services Council to publish its Report was a major issue, and since the publication of the profession's principles in December, 1945.

General Practice

Of the serious current problems the loss of income, often amounting to hardship, of particular groups and particular individual practitioners is perhaps the first. Representatives of the General Medical Services Committee headed by its new Chairman, Dr. Wand, made representations to the Ministry on this subject, with particular reference to rural practitioners. Three rural practitioners—one from Cumberland, one from Somerset, and one from Norfolk—gave a first-hand account of the conditions of rural practice to-day. The request for an immediate and a substantial increase in the Mileage Fund to deal with the general rural problem was sympathetically received by the Ministry. We shall know the outcome early in the New Year.

The second main problem is the general one of the application of Spens to both urban and rural practitioners. The first investigation, undertaken in Lancashire, is complete. Investigations are being made with all possible speed into a number of sample areas—Bath, Halifax, Norfolk, Nottinghamshire, and Nottingham—following the lines shown in this column last week. The object of the inquiry is to find out what in fact are the ranges of income received by general practitioners and how they compare with the Spens recommendations. This investigation is an indispensable preliminary to any application for an overhaul of remuneration. It is hoped that it will be complete in all the sample areas in four or five weeks' time.

The third problem, closely associated with the second, is that of the increase of work, particularly work of a non-medical character. In one respect the solution here must await the Report of the Government Certificates Committee, on which the profession is powerfully represented; the Association has given its evidence to this Committee. In another respect it is closely associated with the Spens Inquiry and bears on the question of the number of approved maximum on lists. For this reason the two issues of remuneration and burden of work will be raised with the Ministry together as different aspects of the same problem as soon as the special investigations are complete.

At the same time representations are being made to the Ministry on a host of other points. It has been asked for and has promised a speedy settling up of moneys due to insurance practitioners as payment for the first four days of July and a final settling up of N.H.I. payments. A speeding-up of the discussions of payment for immunization and vaccination has been pressed so as to enable practitioners to be paid for this work retrospectively to July 5. We are promised that the model distribution scheme will soon go out to enable payment to be made for work done for temporary residents since

the appointed day. We have pressed and hope to get mileage payments in connexion with the maternity scheme. A brief statement of a number of other points raised in an interview with the Ministry a fortnight ago will be found on another page of the *Supplement*. In short, a steady but heavy pressure is being applied to the Ministry on a wide front. We are determined to secure really satisfactory terms and conditions of service.

Consultants and Specialists

In this field the Consultants and Specialists Committee established by the Association is now participating with the Royal Colleges and the Royal Scottish Corporations in a Joint Committee which will negotiate on matters arising out of the Acts and the Specialist Spens Report. Sir Lionel Whitby, Regius Professor of Physic of the University of Cambridge, President of the Association, has accepted an invitation to become the Chairman of the Committee. It met on Dec. 17 and will meet again on the morning of Jan. 7, meeting representatives of the Ministry on the afternoon of that day. At last the work of negotiating the national scale of remuneration for consultants and specialists has got under way. It is no breach of confidence to say that the first issue to be tackled is that of the security of tenure of consultants and specialists in the new service.

Public Health Service

A vigorous attempt is being made to get these negotiations under way. It was thought wise to await the publication of the Specialist Spens Report in order that both Spens Reports might form the basis for negotiation of public health remuneration. Following the publication of this report we sought to clear away the remaining difficulties about Whitley machinery. This was done. Then we were confronted by delay arising from the difficulties in the minds of the Associations of Local Authorities. The Public Health Committee of the Association at its last meeting decided that this delay could not be allowed to continue, and, in consequence of a recommendation they are putting to the Council in January, I have written to the Ministry of Health in the following terms:

"At a meeting of the Public Health Committee of the Association held on Dec. 17 I reported on the present position with regard to the setting up of the Whitley machinery. The Committee expressed great dissatisfaction and disappointment at the continued delay in opening negotiations and resolved that the following recommendations be submitted to Council at the meeting on Jan. 12, 1949:

"(a) That the Ministry be informed of the serious unrest and dissatisfaction among members of the public health service occasioned by the continued delay in the opening of negotiations on new scales and conditions of service.

"(b) That the Ministry be informed that if negotiations through the approved Whitley machinery have not begun by Feb. 28, 1949, advertisements from local authorities will not be accepted by the *British Medical Journal* unless the salaries offered are in conformity with the Association's own proposals for new scales.

"(c) That negotiations be conducted on a national basis covering England, Wales, and Scotland.

"The profession's representatives have been nominated and are ready to start discussions at once."

Other Groups of the Profession

A case is being prepared for the revision of remuneration in the Colonial Medical Service on the basis of the Spens

Reports. When the negotiations for consultants and specialists are complete the work will be begun of seeking the appropriate application of the Spens Reports to other groups of the profession, including the armed Forces, non-professorial teachers, research workers, industrial medical officers, and Civil Service medical officers. The Spens Reports will no doubt have wide repercussions, but that fact need not prevent us from securing their appropriate application to the two groups of the profession to which they apply directly and to all other groups of the profession to which by implication they relate.

Constitution and Organization of the Association

Discussions under this heading are almost complete. The Committee which has been studying the constitution of the Association in relation to trade union status is now preparing its report. The Organization Committee has been re-examining other aspects of the Association's organization, including the

structure and functions of the Representative Body and the Council. At its last meeting it had the advantage of a vigorous personal contribution from three representatives of the Winchester Division—the authors of the Winchester Memorandum. The fruits of these inquiries should come before the Association in the early part of 1949.

A New Venture

From now on, members of the Association will be able to enjoy without charge the services of the Medical Practices Advisory Bureau which is now being established to advise on problems associated with entering practice and to introduce locums, assistants, and principals. In short, the services once provided by the British Medical Bureau are now available as a free service to members of the Association. It is hoped in time to amplify the service by providing information on appointments and opportunities in other branches of medicine.

National Health Service

AWARDS TO SPECIALISTS COMMITTEE APPOINTED

The Minister of Health and the Secretary of State for Scotland have appointed a committee of 14 members in accordance with the Spens recommendations to advise which specialists engaged in the National Health Service should receive awards for professional distinction, "having regard to the desirability that % of the number eligible should receive the highest award, % the second award, and 20% the third award." The following are appointed: Lord Moran (chairman), Sir Horace Hamilton (vice-chairman), Mr. V. Zachary Cope, Professor Geoffrey B. Fleming, Sir Gordon Gordon-Taylor, Mr. J. M. Graham, Sir David K. Henderson, Sir Edward Mellanby, Mr. J. F. Mountford, Professor Sir Harry Platt, Professor A. L. Robinson, Mr. J. H. Sheldon, Sir Lionel Whitby, Mr. J. M. Wyatt. Mr. T. B. Williamson, of the Ministry of Health, is secretary.

Eleven members have been nominated by the Royal Colleges and Scottish Royal Corporations, one by the Medical Research Council, and one by the universities' committee of vice-chancellors and principals.

MEETING WITH MINISTRY CONDITIONS OF SERVICE DISCUSSED

Representatives of the General Medical Services Committee have had discussions with officers of the Ministry on the following matters in connexion with the National Health Service.

Maternity Medical Services

Administration of Anaesthetics.—It has been suggested that the fee for the services of a second practitioner administering an anaesthetic in maternity cases, together with mileage where claimed, should be paid direct to that practitioner, and with a view to giving effect to this arrangement the name and address of the practitioner concerned, with details as to mileage travelled, should be included in Forms E.C.24 and 24A.

The Ministry has agreed to explore the possibility of putting this recommendation into effect.

Mileage.—It has been recommended that the obstetric fee should be subject to some extra allowance in rural areas in view of the distances to be travelled.

A fee of 1s. a mile each way beyond the two-mile radius has been suggested.

The Ministry is examining the problem.

Certificates to Pregnant Women.—It has been urged that in the case of pregnant women at or about the 36th week the practitioner should be required to give only one certificate to cover the interval to the actual confinement. Such a procedure would be a convenience both to the expectant mother and to the practitioner.

The Ministry of National Insurance has agreed in principle to this suggestion and an agreed announcement will be made in the *Journal* as soon as possible.

Forms E.C.24 and 24A.—Cases have arisen where for reasons beyond the practitioner's control—e.g., patient's change of residence, holidays, etc.—the practitioner has been unable to undertake the necessary antenatal examination "at or about the 36th week," with the result that there is doubt whether the fee is payable. It is understood that in such cases the Department has agreed that the payment of the fee should not be dependent upon carrying out the examination in the period defined.

The Ministry has agreed to make the position clear to local executive councils.

Details of Maternity Fees.—It is the Ministry's view that clerks of executive councils should furnish practitioners with an itemized statement when payment is made in respect of maternity cases.

It is thought that this will be useful to practitioners in scrutinizing payments due to them.

Forms of Application for Maternity Benefit.—A number of practitioners have asked that a supply of forms of application for medical benefit should be made available to them.

The Ministry of National Insurance has already issued instructions to this effect.

Miscarriages

Inquiry was recently made of the Department for a statement on the position of a doctor called to a miscarriage, no previous arrangements for maternity medical services having been made between the patient and the doctor.

The Department replied:

"In such cases we think the doctor, if the patient is his own patient, would give the necessary treatment (without payment) as part of his ordinary obligations as a general practitioner. If the patient was on another doctor's list, he would have no responsibility (unless he were called in when the patient's doctor and his deputy were not available, in which case the emergency arrangements would apply)."

The Association cannot accept the Department's view that treatment for a miscarriage should be regarded as part of the ordinary obligations of a general practitioner under his terms of service, and the Ministry has been so informed.

The Ministry's reply on this point is awaited.

Dental Haemorrhages

It has been recommended that medical practitioners called out to cases of dental haemorrhage following dental extractions should be remunerated for this service. It has further been represented that any payments made should not come out of the Central Practitioners Pool.

Telephone Charges

Practitioners, especially those in rural areas, complain of the heavy cost of telephone charges where action is necessary to obtain an ambulance or to secure the patient's admission to hospital. In the Association's view it is unreasonable that the cost of this service, which is provided by the practitioner for the benefit of his patient, should be borne by the practitioner. It has been suggested that, in respect of other than local telephone calls, practitioners should be able to reverse telephone charges where a call is made to a hospital, on behalf of one of his patients, for the purpose of admitting a patient to hospital, for ambulance facilities, etc.

The Ministry has agreed to explore the possibility of giving effect to this recommendation. In the meantime the Secretary will be glad to have information from practitioners of undue expenditure under this heading.

Postage on Official Communications

The Ministry has again declined to support the Association's contention that the proper method of reimbursing doctors for postage of documents to the executive councils is by the issue of officially franked and addressed envelopes.

Missing Information on Form E.C.1

Numerous complaints have been received from practitioners who have been asked by local executive councils to obtain information omitted by patients when completing Form E.C.1.

The Ministry agrees that this information should be sought from the individual and not from the practitioner.

CLAIMS FOR COMPENSATION

The closing date for the submission of claims for compensation was Oct. 31. The Minister is empowered to grant extension only where he is satisfied with the reasons for delay. Any doctor who has not sent his claim to the Ministry of Health should do so at once, and his return should be accompanied by a statement of the circumstances which made it impracticable to submit the claim by the due date.

REMUNERATION IN ARMED FORCES AND C.M.S.

The subcommittees which have been conducting detailed examinations of the remuneration of medical officers in the armed Forces and in the Colonial Medical Service in relation to the two Spens Reports have now completed their labours. They will report to their parent committees in the New Year.

AMALGAMATION OF THE MALAYAN MEDICAL SERVICE

Four Asian members of the Malayan Branch recently visited Headquarters and gave the views of Asian doctors upon the Malayan Government's proposals for the unification of the Malayan Medical Service.

N.H.I. FINAL SETTLEMENT PAYMENTS DELAYED

Many general practitioners who had panel patients before the National Health Service started are anxious about the Final Settlement under the N.H.I. scheme due to them for the first two quarters of 1948. It has not yet been paid. The provisional payments for the first two quarters were based on the average number of insured persons in the various areas during the preceding year. During those quarters some patients went on or came off panel lists, and the Government Actuary's Department determines mean figures to take account of these people. The delay in calculating the figures is in that Department. When the figures are available—and they should be very shortly—they will be submitted to the Distribution Committee, on which the B.M.A. has representatives. It is expected that the money will be paid out at the end of January.

Questions Answered

Income Tax and Practice Expenses

Q.—Have the income tax authorities agreed with the figure of 35% deduction from the capitation fees, and 50% from mileage fees, as practice expenses which have been made when calculating superannuation contributions?

A.—The figures of 35% for practice expenses and 50% in the case of mileage payments have been adopted solely for the purposes of the National Health Service superannuation scheme. They have not been agreed with the income tax authorities. In any case the individual practitioner's assessment for income tax is a matter for arrangement between himself and the local income tax authorities.

Compensation on Retirement

Q.—If a general practitioner wishes to give up general practice and take up another branch—e.g., industrial medicine—before the retiring age of 60 or 65, can he do so and draw his compensation money for investment according to his own risk?

A.—Under Regulation 13 of the National Health Service (Medical Practices Compensation) Regulations, 1948, the compensation payable to a practitioner will be paid on his retirement from practice or death, whichever occurs first. For the purpose of this regulation retirement from practice means retirement from practice as a medical practitioner providing general medical services under Part IV of the Act or under Part IV of the National Health Service (Scotland) Act, 1947. A practitioner receiving compensation on retirement from practice in the Service does so without prejudice to his right to engage in other fields of medical work.

Entering General Practice

Q.—I am at present serving in the R.A.M.C. and expect to be released next year. How do I set about entering general practice?

A.—The Medical Practices Advisory Bureau can give you information about entering general practice. It is under the direction of a member of the medical secretariat, and its address is B.M.A. House, Tavistock Square, London, W.C.1.

PENALTIES OF OLD AGE LIBERAL PARTY'S VIEWS

At a meeting of the Liberal Party Council held recently the following resolution was passed unanimously:

"That this Council, in these days of full employment and shortage of manpower.

(1) deplores the absence of any constructive policy by the Government for enabling the elderly to maintain a happy and healthy life beyond pensionable age by opportunities for creative employment where they are physically able and willing to continue working, and
(2) calls upon the Government to encourage those of pensionable age who are willing to continue work to do so without penalization;
(3) calls upon the Government as a measure of great urgency to bridge the gap between the National Health Service Act and the National Assistance Act by the establishment of statutory committees representing the regional hospital boards, the local health authorities, and the appropriate voluntary bodies;

(4) urges the Government to increase the provisions for admission of old people into hospital, who are now too frequently excluded solely on the grounds of age."

It was moved by Lord Amulree and seconded by Dr. J. A. Gorsky. Lord Amulree commented on the short-sighted policy of the Government which at present penalizes those able and willing to continue working beyond retirement age if they do so, and urged that the pension should be paid as of right, irrespective of whether the elderly continue with their jobs or not. Such a Liberal policy would improve the manpower situation and in a great many cases would be of benefit to the elderly themselves, who too often tended to die off when the motive power of their lives was removed. He also deplored the lack of hospital accommodation for old people, and commented on the difficulties of the medical profession in gaining admittance to hospital for old folks.

HEARD AT HEADQUARTERS**B.M.A.'s Libel Action**

Medical charities will benefit by a "substantial sum" as the result of the settlement of the libel action of the B.M.A. against "Daily Mirror" Newspapers Limited. In spite of a natural reluctance to use the instrument of a writ for libel, the Council felt that in this instance what it judged to be an imputation of dishonesty against the Association and its officials could only be satisfactorily met by bringing the matter into court. The policy of the Association is often attacked and is expected to be attacked in the same way as the policy of the Government or any corporate body, but it becomes a different matter when the attacks take the form they did in this instance. There is a feeling in some quarters that if an organization is big enough almost anything can be said about it with impunity—that it is so impersonal that it has no character to be assailed. That is not the view which the Association took, and it has been sustained by the Courts. The *Daily Mirror* has withdrawn any imputation which might have been read into its statements in connexion with the conduct of the plebiscite last January, and has agreed to pay a sum to medical charities and to indemnify the Association its costs. In the other action, which concerned four labour M.P.s, they stated that it had never been their intention to impugn the honesty of the Association or its officers or officials. All's well that ends well, and perhaps a lesson has been learned which will be useful for the future.

Private Practice Committee

What has been known for some years now as the General Practice Committee, and before that was known as the Medico-Political Committee, has changed its name. As matters stand, the newly constituted General Medical Services Committee is handling N.H.S. business, and the remnants which belong mainly to the sphere of private practice are the province of what has been the General Practice Committee. Its new title is to be the Private Practice Committee, not strictly logical perhaps, but explanatory, and at any rate the Committee itself could think of nothing better. Dr. Wand, who has been its chairman for nine years, has recently been translated to a more capacious seat, and the Committee has chosen Dr. I. G. Grant, of Glasgow, for its new chairman. The Committee has still plenty to do, especially concerning fees for work for local authorities, national boards, insurance companies, and Service departments, as well as innumerable other matters.

Mining Accidents

When an accident occurs at a coal mine all the doctors from a considerable radius may be summoned, and of course, as is their duty, they attend. A point to which scant regard has been paid hitherto, but which, with nationalization of mines and the setting up of the National Coal Board, is now being looked into by the Association, is the risk of accident which such doctors themselves may run. They are practitioners probably drawn from a wide area and unaccustomed to the, at first, rather alarming conditions of the interior of a mine. Even under the best conditions such underground traversing is attended by minor risks of bruising and so on, and it is all a novice can do to keep his feet and his sight; where there has been an accident the risk is possibly intensified. The duty of the doctor to attend is not questioned, but the point is being raised about the compensation to the doctor or to his dependants in the event of injury or death.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

WHITLEY MACHINERY AND PUBLIC HEALTH SALARIES

A meeting of the Public Health Committee of the Association was held on Dec. 17 under the chairmanship of Dr. James Fenton. Dr. J. A. Ireland voiced the pleasure of the whole committee on seeing Dr. Fenton back in his usual place, recovered from a serious illness.

A report was given by the Secretary (Dr. Charles Hill) on the question of the setting up of Whitley machinery for public health salaries. He gave an account of correspondence and conversations with the Ministry of Health. At the end of November it was intimated by the Ministry that the associations of local authorities wished to discuss certain matters before the Whitley Council was set up, and that it might be a little time before the first meeting could be arranged. It was to be assumed that the secret of the difficulties was that it had suddenly been realized that the subcommittee of the Whitley Council would be backed by arbitration in the event of disagreement, and that the recourse of any arbitrator would be to the Spens Reports in order to determine his award, a circumstance which might have repercussions in other fields. But the delay was most unsatisfactory. The Association had been anxious to have negotiations for the new scales completed and to have the Whitley machinery embodied in the agreement.

The meeting discussed possible ways in which the setting up of the machinery might be expedited. One member suggested that it was obvious that the local authorities had no intention of collaborating in the setting up of the Whitley machinery, and that two courses were open to those who represented public health medical officers. One course would be to approach the Minister, pointing out the impasse, pointing out also that the Spens Reports were now operable, and should be referable to public health medical officers, and that the Minister be asked to lay down by regulations the scale in accordance therewith. The other course would be to declare that unless negotiations had been begun by a certain early date advertisements for appointments which did not conform with the new proposals would be refused.

After some discussion it was agreed to recommend to the Council of the Association at its meeting early in January that the Minister be informed of the delay in opening the negotiations on the Whitley basis, and that unless such negotiations had begun by Feb. 28 advertisements for appointments which did not conform to the proposals laid down would not be accepted.

It was the unanimous view of the Committee that the Whitley method, backed by arbitration, was the method of choice. The Committee proceeded to select its representatives on the negotiating body, the endeavour being made to cover as wide a field of public health service as possible. The following were appointed: The Chairman of Council (Dr. Dain), the Chairman of the Committee (Dr. Fenton), Dr. Metcalfe Brown, Dr. George Buchan, Dr. J. A. Ireland, Dr. R. H. H. Jolly, Dr. Jean Mackintosh, Dr. Wyndham Parker, Dr. J. Riddell, Dr. J. A. Stirling, and Dr. Hill.

Other Business

The Committee heard with satisfaction that the National Veterinary Medical Association had welcomed the proposal for the setting up of a joint committee to formulate for transmission to Government departments representations on the problem of providing milk of high quality for the community and the supervision of the production and distribution of other foods of animal origin. Three B.M.A. representatives had already been appointed to the Committee, but the Veterinary Association suggested that the numbers should be six on each side, and to this the Committee agreed and appointed three additional B.M.A. representatives, one of them to represent Scotland.

The Committee nominated its Chairman, with Dr. Buchan and Dr. Jolly, to join with representatives of the General Practice Committee in discussions with the local authorities associations on fees for services to local authorities.

The meeting considered a statistical summary which had been prepared showing the present position with regard to equal pay for men and women medical officers. It was stated that

there had recently been an improvement in this respect in the direction of B.M.A. policy, and the Committee felt that the figure reflected great credit on the work of the office. A very large number of the smaller authorities (municipal boroughs and urban and rural districts) from which no replies had been received employed no women medical officers.

The Committee considered the Milk (Special Designations) Bill, the Civil Defence Bill, and other matters.

Correspondence

Remuneration and Size of Lists

SIR,—Now that a subcommittee of the British Medical Association is considering all the aspects of the remuneration of general practitioners with a view to presenting a case for revision of the present inadequate capitation fee to the Minister of Health, it seems profitable to set out how the problem appears to the writer, who is an urban practitioner with a list rather below the present maximum of 4,000. There would appear to be four separate factors involved: first, the report of the Spens Committee; secondly, the volume of work which a general practitioner can reasonably undertake; thirdly, the relation of this to the limited number of practitioners now available in the country and their uneven distribution; and, fourthly, the capitation fee and size of practitioners' lists necessary to correlate the first factor with the second and third. It might be profitable also to consider future developments.

It is important in the first place to recognize clearly what the Spens Committee recommended. They did *not*, as seems to be frequently believed, advise any particular capitation fee. They recommended that certain proportions or percentages of practitioners should earn certain incomes. Thus, 20% of all doctors should earn £700–£1,000, 24% £1,000–£1,300, and so on. By making certain assumptions it is possible to calculate that the average income of the general practitioner, in 1939 values of money, should be about £1,300 plus rather less than half as much again for those practice expenses allowed by the income-tax authorities.

To the figure thus obtained must be added a "betterment" factor for the fall in value of money since 1939. This does not mean such an increase would produce the same purchasing power then and now. Other factors, especially the actual rise in the income of other comparable groups of the community, have to be taken into account. It has been stated that the Ministry are working on a betterment factor of 20%. If this is to be fairly applied it must be remembered that it must apply to the net portion of the income only. That portion of the earnings representing practice expenses must be increased to cover the actual cost of these expenses at the present time. Otherwise the 20% increase in his real income will not reach the doctor at all but will be swallowed up in the much larger percentage increase in the practice expenses.

As this point is of the utmost importance, it might be well to illustrate it by the example of the "average" £1,300 income. The practice expenses, at 33% of the gross income, would be £650, but, as the drug bill is no longer a charge on the income and there is also some saving in the cost of collection of accounts, the comparable 1939 figures might be taken at: income £1,300, expenses £500, total gross £1,800; add 20% = £2,160. In fact, however, the practice expenses which remain are all items which have increased beyond the ordinary proportion. House property over 200%, car transport perhaps 100%, wages about 100%, and so on. If you take net income: £1,300 + 20% = £1,560. Expenses £500 + 100% = £1,000. Total gross income should equal £2,560, or £400 more than the first case. This point is worthy of a full statistical investigation and should not be overlooked.

The Spens Committee gave no guidance on the volume of work a practitioner can reasonably undertake, but if their findings are to be applied to a capitation fee system it is obvious this matter must first of all be considered and settled. It is one of great difficulty, since it involves not only skill but speed of work in addition—consideration, in other words, of both quality and quantity, and these, beyond a certain limiting point, are to some degree inversely proportional.

If the Service is to be other than a sham it must provide time for the proper examination and treatment of all patients as they

require it, and on the other hand the allowance of time must not be so extravagant as to put it out of all reason. The Spens Report on dental services suggested 42 hours a week as reasonable, including clerical work. It must not be forgotten that the doctor has far more urgent calls out of routine hours. For that reason I do not consider he should be called on to work in his consulting-room and on his routine visits for more than at the most 36 hours weekly—i.e., six hours daily six days a week. In my view, taking all the factors into consideration, he should be able to attend 27 patients in his consulting-room in three hours, and 12 patients in their own homes in the other three hours—39 patients daily, or 234 a week. Adding two special visits out of time on each of six weekdays and four on Sundays gives a week of 250 attendances, which I suggest should be the normal maximum for the average man earning the average income.

I am well aware that many men do more: I do myself; but I believe that, if this maximum be largely exceeded, this can only be done at the expense of proper unhurried and well-considered diagnosis and treatment. I cannot feel that some 6½ minutes per consultation and 15 minutes for a visit, including time spent in travelling, can be regarded as excessive.

Now, the pre-war panel patient required, on the average, about five attendances a year. I do not know of any later statistics. It is obvious that with the young and the aged at risk the demand must rise. There is also now far more incidental certification. The present figure must be guesswork in the absence of statistics. I propose to take a figure of seven items of attendance as probable at the present time. Each thousand patients would then require a weekly average of about 135 attendances the year round, but these would probably be distributed 105 per week for the six summer months and 165 per week for the six winter months. As one must obviously provide for the winter, and I am not speaking of the peak period in time of epidemics, it would appear that the figure of 250 items of attendances a week would limit the average list under conditions of demand obtaining in the present Service to about 1,500 patients. The figure seems low on past experience, but will surprise no one who has tried to keep pace with the demand on a much larger list during recent months, which have not yet nearly reached the winter peak.

The Parliamentary Secretary to the Minister of Health recently gave the number of practitioners available as rather over 18,000. As the number of patients at risk is over 45 million, this gives an average of about 2,500 per doctor, although the assistants' list will somewhat reduce the proportion. Further, any maldistribution of doctors would of course increase the average lists of practitioners in industrial areas, which it would seem cannot be much below 3,000.

If, as has been suggested above, the proper average list is 1,500 and the Spens Committee findings provide for an average gross income at the present time of about £2,500 at least, it follows that the equitable capitation fee should not be less than 33s., and this is calculated on a betterment factor of only 20%. It would, in my view, be just possible for the exceptionally hard and quick worker to increase his list to 2,250 and earn the upper range of income advised by the Spens Committee, but above this figure he can only go at a risk of killing himself and his patients. If the figure of seven items of service a year is justified, more patients can be fitted into the day only by cutting down the time given to each or by increasing the total hours of work. I think it is perfectly clear that both these courses are highly undesirable.

It may be asked what happened before July 5. I think the answer is that the economic factor kept down the numbers outside the panel and also that the doctors as a whole were becoming more and more overworked and underpaid. The panel fee of 10s. 6d. up to 1945 was almost ludicrous. I do not remember any of the panel fee inquiries in the past making any attempt to find out what volume of work a man could undertake or what income he could or should earn. Whatever happens now, the present doctors must for some years continue to be seriously overworked. I suggest that if a major breakdown is to be avoided they must be paid sufficiently adequately to enable them to be relieved of financial distress and to enable them to pay for such secretarial and other assistance as may help them to deal with the volume of work.

Some of the quality may have to be let go temporarily in order to deal with the quantity. I think it is essential to establish the correct average list according to the conditions of work, not according to the availability of sufficient practitioners to deal with the population. Then, if it is necessary for the limited number available to cope with the demand of an undue number of patients, at least it will be realized they are being overworked, and then increased remuneration will attract enough men into general practice to balance ultimately the figures and the situation.

Given that the figures I have suggested are substantially correct, I would make the following concrete suggestions: The

capitation fee be fixed at present at about 27s. The maximum list reduced from 4,000 to 2,750. Some latitude might have to be given for a short time in some areas. For the next five years the maximum list be reduced 100 each year and the capitation fee increased by 1s. At least 1,000 new general practitioners be attracted into practice each year and if necessary assistance given to get them settled.

Perhaps the first need of all is for a clear understanding of this complicated problem for all concerned, the doctors not less than the Ministry.—I am, etc.,

Thornton Heath, Surrey.

REGINALD N. DEANE.

* * * The percentages quoted in the second paragraph relate not to all practitioners but to practitioners in the 40-49 age group (Spens Report on General Practitioners, p. 5, Table B).—Ed., B.M.J.

Raise Capitation Fee

SIR,—We read in the Press that Mr. Bevan considers that a dentist may reasonably earn £4,800 per annum—this with a shorter training, little or no postgraduate experience, no night work, no life-and-death responsibility, and six weeks' annual holiday. It is claimed that expenses amount to 50% (although this is doubtful out of such large earnings), leaving a net income of £2,400.

The average general medical practitioner can only have 2,000 patients (total population divided by total of practitioners). From these his gross income will be approximately £1,750, plus about £200 from private patients and £350 from confinements, etc. Deduct 35% for expenses and his net income is less than £1,500. A general medical practitioner should be entitled to a financial return at least equal to his dental colleague. Unfortunately those G.P.s with lists of 3,000-4,000 are apathetic; they are unable to see the writing on the wall—health centres. When these are established it will be precisely in those areas where these large lists exist. They will be staffed by young G.P.s now pouring from the medical schools (and who won't want to starve in rural or suburban areas) and living perhaps in council houses. With no financial obligations for a practice or house, they will soon eat into the long lists of their neighbours. Then perhaps these presently apathetic and apparently financially secure practitioners will feel the pinch in their turn; if they are to protest, they should do so now.

Similarly, unless the B.M.A. presses more strongly, those of us with smaller lists who are already feeling the financial draught are going to be driven to join a "splinter group" or perhaps a rural organization. Sir, the B.M.A. must demand a capitation fee of 30s. and £10 10s. for a confinement. Only then will the average G.P.'s net earnings equal those of a dentist.—I am, etc.,

Stockport, Lancs

J. HEGINBOTHAM.

Training Assistants in Rural Practice

SIR,—I see that doctors are to receive grants for training assistants, provided their practices number over 2,000 patients. May I put in an urgent plea that for the dispensing doctor the number may be substantially reduced?

In a town practice the majority of the patients live in the vicinity of the doctor's house, so that visits are close together and many patients can attend at the surgery. Treatment for the most part consists in writing a prescription to be made up by a chemist near by. A dispensing practice covers an extensive and thinly populated area; visits may be miles apart, and only a fraction of the patients can reach the surgery. In particular, mothers and small children cannot make a cross-country journey to the doctor's house, and so help to swell the visiting list. In addition, the doctor has to carry out the whole work of a chemist—laying in stores of drugs, making up all kinds of prescriptions, and distributing to the patients over a wide area. I believe that 1,500 patients will give the dispensing doctor more work than 2,000 patients in a town practice.

At the beginning of the war I revived the travelling dispensary as used for village medical work in India. In a crate I carry tablets, powders, and concentrated stocks, together with the necessary bottles, corks, and labels. I dispense by the roadside, in farmyards, and in cottage kitchens. The dispensary is immensely popular, as it saves patients sending long

distances for their medicines and it ensures that treatment is begun promptly, but it does slow down the round, and the dispensary has to be restocked nearly every night.

I trust my plea will have favourable consideration.—I am, etc.,

Invergowrie, Scotland.

RUTH M. MONRO.

Car Expenses of Whole-time Specialists

SIR,—I wish to endorse the letter in the *Supplement* of Dec. 18, 1948 (p. 229), from the whole-time specialists of Leicester. Two years spent in queueing for trams, buses, and ferries taught me how deadening to professional enthusiasm such transport can be. The acquisition of a car has enabled me to indulge in many "unofficial" visits to hospitals, reference libraries, clinical meetings, etc. Such visits are not demanded of me, but they are essential to the maintenance and improvement of the degree of professional skill expected of me.

A car is not, therefore, a luxury bestowed upon professional men, but rather an indispensable condition without which their work cannot be undertaken efficiently. Without car expenses it would be financially sounder to travel by tram or bus and continue at a level of professional mediocrity. The annual outlay on running a car amounts to a voluntary contribution to the national exchequer.—I am, etc.,

Liverpool.

ARTHUR S. WIGFIELD.

Remuneration Not Agreed

SIR,—The time has come for plain words. On Dec. 1 the Minister of Health stated, in answer to a question by Sir E. Graham-Little: "The remuneration of general medical practitioners . . . was agreed with the profession." This is not true. At no time did the discussions with the Minister cover remuneration. The Minister's terms of remuneration were announced by him at his last interview with the Negotiating Committee, and the Committee did not agree them but reserved the right to enter into negotiations on them.

The plain facts should be plainly stated, and the Minister's statement plainly rebutted. May we expect an immediate and authoritative statement from the Negotiating Committee?—I am, etc.,

Worcester Park, Surrey.

ROBERT V. GOODLIFFE.

* * * The Secretary of the Association writes: Dr. Goodliffe's statement is accurate. The Minister and the profession accepted the Spens Report. Such is the character of the recommendations of the Spens Committee that it is only now becoming possible for anyone to say whether they are being implemented. For example, it was not possible before the appointed day to say whether or not the Minister's proposals would in effect secure that 50% of general practitioners would receive £1,300 a year net in terms of pre-war money values—i.e., £2,613 a year after conversion into gross and the application of the betterment factor laid down by the Government. Investigations are now proceeding in a number of areas to determine whether in fact Spens is really being applied. The first investigation is complete and four others are now in progress and likely to be completed in three or four weeks' time. Further, the Spens comment on mileage was that

"So far we have discussed solely the position in regard to urban practices. We do not regard as significant the comparatively small differences which Professor Bradford Hill's figures indicate as between urban and mixed practices. The latter have produced somewhat larger incomes, but the difference is not great, and it is far from clear whether this difference would persist in a publicly organized service. A more serious problem exists in regard to incomes from rural practices. We are not prepared to criticize the existence of a difference between the average remuneration of rural and urban practice, having regard to differences in cost of living and amenities; but we consider that the difference of approximately £200 which existed in 1939 between incomes about the £1,000 level in the two classes is excessive and requires reduction by about half, when regard is had to all the facts involved. It appears probable that this could best be secured by weighting mileage more heavily."

It is now becoming obvious that the mileage fund will not bridge the gap, or any substantial part of the gap, between urban and rural remuneration. The negotiations on this point are in the hands of the General Medical Services Committee and a further meeting was held with the Minister on Dec. 22. It is hoped to make a report soon.

Remuneration

SIR,—Will you kindly publish in your correspondence columns the following resolution passed by my committee? "That the British Medical Association should not agree to the fixing of any central sum from which all remuneration should be paid to practitioners;

"That the capitation fee, as finally agreed, should be paid in full and without delay and be subject to no deduction."

It was felt very strongly that the Minister has no moral justification for not paying the full capitation fee as agreed. The assumption that a fixed central sum only should be available was of course based upon the old N.H.I. and does not apply to-day to what is a non-contributory service—thus termed by the Minister in Parliament. Any negotiations based on the assumption that there is this fixed central sum and nothing more must invariably lead to general dissatisfaction among the rank and file of doctors in active practice. It is obvious that the firmest action must be taken to procure the obvious rights of the profession, and it is hoped that all over the country local medical committees will insist upon determined action by their spokesmen. A sitting-down war will get us nowhere.

As regards the basic salary, the present position is grossly unjust to all parties. Where justification exists for the granting of a basic salary, let the Minister be generous with his own funds and not with moneys designed for payment of capitation fees.—I am, etc.,

J. GORDON-WILSON,
Hon. Secretary,
Eastbourne Local Medical Committee

Foreign Visitors

SIR,—If the National Health Service Act covers all foreign visitors to this country who care to take advantage of its provisions—and that, so far as I can gather, without previous contributions—the Ministry of Health are surely in a quite untenable position when they refuse pharmaceutical benefits to private patients who do pay contributions. The Minister himself has said that everyone is eligible to use the whole service "or any part of it."

If he goes back upon this plain statement, and yet extends all the facilities to foreign visitors, then he is in the invidious position of providing free to foreign nationals benefits which he denies to British citizens who are finding the money for those benefits. Surely this is an intolerable and unjust state of affairs. I heard the other day of a foreign visitor to this country who laughed at our foolishness as he returned home with two pairs of spectacles and a set of false teeth at our expense.

It is quite time that such injustices and anomalies should be set right, and it is to be hoped that our negotiators will, without delay, tell the Minister that the medical profession is no longer content to submit to abuses of this kind. It is up to us to protect our patients' interests as well as our own—and indeed it seems as though nobody else is left to do so. One is impelled to wonder whether the present unsatisfactory position would ever have arisen had not our Association sacrificed its prestige by its policy of appeasement and its disastrous surrender in May. Let us all remember that the fear of losing compensation no longer hangs over our heads and that the threat of resignation is a potent weapon.—I am, etc.,

Wolverhampton.

VICTOR RUSSELL.

Married Ex-Service Hospital Residents

SIR,—I am pleading here for a minority of the profession—namely, married ex-Service hospital residents, whose needs for an early increase of remuneration are more urgent than those of the more vocal and better represented majority. It is more than 10 years since I qualified. I am married and have three children. After 5½ years of service I was released from the Army and had to provide a home for my family by over-drawing my bank account. Now, almost three years later, I am still uncomfortably in debt.

After holding a holding appointment under the release scheme, and after a period of unemployment, I decided to train in pulmonary tuberculosis. To support my family I earn little more than "P. D." (*Supplement*, Dec. 4, p. 211) would like to spend on education of his children. My income provides bare subsistence, and, although I do not lack clothing

coupons, certain clothes, as well as certain foods, house repairs, holidays, and medical textbooks and journals, are unobtainable luxuries. A more remunerative, non-resident post would increase the burden of debt, because I should need to move house at a time when costs are higher than formerly, and I should probably need a car.

There has been a suggestion of interim relief for those in my position if a settlement is otherwise long delayed. For me even three months is a long delay, an intolerable delay, but even an inkling of what the future may have in store would be more helpful than the present hopeless obscurity.—I am, etc.,

D. F. S.

Directives

SIR,—I have just received from Salop Executive Council a directive which states that patients requiring medical or surgical appliances must be referred with a letter to a consultant at the Royal Salop Infirmary and should attend on Wednesdays. Is it possible to conceive a more absurd rule? Consultants are required for the purpose of consultation on certain types of case and are already finding it difficult to get through the numbers of cases attending out-patient departments. Why then add a quite unnecessary task?

Let me give an example. Two days ago a mother brought her infant to have an umbilical belt replaced owing to wear. Do the authorities really consider it sensible that this mother should travel 28 miles to Shrewsbury, paying her fare, arranging for another woman to look after her other baby, wait for perhaps four hours in the out-patient department, and waste the valuable time of a consultant over such a trivial matter? Really it is reminiscent of directives received when in the Army. Or take the case of a patient requiring renewal of a colostomy belt, a truss, or any other appliance: surely such a service can be rendered by the patient's own doctor, or do the authorities consider us all completely incompetent? During the discussions over the Service I often warned my colleagues about the types of directives we should receive. This is a typical example.

It does not impress one that the best and most intelligent people have been placed in authority over us. Would it not be a good idea to place more general practitioners on committees required to decide such matters as these and guide the bureaucrats?—I am, etc.,

Ludlow, Salop

VICTOR N. FENTON.

* * A general practitioner may prescribe trusses on Form E.C.10, and also order repairs and replacements of colostomy belts and cups and of suprapubic belts (see *Supplement*, Nov. 13, p. 172).—Ed., B.M.J.

Rural Practitioners

SIR,—It is clear from the letters of Dr. Hugh B. Muir and Dr. Verna Kendall (*Supplement*, Dec. 11, p. 220) that something must be done to rescue rural practitioners. I would go further than asking for thorough investigation. What is wanted first and foremost is a bonus to all practitioners with less than 1,000 on their list. The bonus should be greater by at least 30% for such as practise in rural areas. Those with less than 500 patients need a double bonus.

The countryside will be denuded of doctors very soon if immediate help is not forthcoming; and all parts of the country, town and rural, will eventually be denuded of all those doctors who would have prospered and continued to practise if they had not been ruined while trying to acquire their first 1,000 patients. If any of us had time, we should perhaps organize propaganda in the lay press and follow that up with processions to Downing Street.—I am, etc.,

New Milton, Hants.

MARY EDWARDS.

Whole-time Specialists Appointed to Hospitals

SIR,—I wonder whether you will allow me to take a few lines of your valuable space to endeavour to bring to the notice of the Negotiating Committee the special position of those whole-time specialists who were appointed to hospitals under the terms of the Ministry of Health Circular 202-46.

I feel it was not intended that these specialists should continue in whole-time employment after the complete establishment of the National Health Service, yet unless regional boards are instructed to grant an adequate number of sessions

to these people most will be forced through serious financial difficulties to continue in whole-time employment, because the terms of their employment have effectively precluded them from developing a private practice in their specialties.

This matter is giving very serious concern to individuals employed under the terms of the circular, and some pronouncement by the Ministry seems overdue.—I am, etc.,

Birkenhead.

C. M. MILLER.

All Resign

SIR,—From Mr. Bevan's reply in Parliament on Dec. 1 to Sir E. Graham-Little's question (*Journal*, Dec. 11, 1948, p. 1042) it is quite apparent that the Minister considers our present remuneration is in full accord with the recommendations of the Spens Committee. As no other person—apart from the Minister—can possibly hold this view, it is time now that we should disillusion him.

In the humble opinion of one whose rural practice now brings in £1,000 less than before, with double the work, the only way to do this is for the profession as a body to resign from the National Health Service. Any difficulties in the way of this, such as the constitution of the B.M.A., the question of so-called compensation, another plebiscite, the resulting chaos in the Ministry of National Insurance, etc., are mere details. The Minister has broken faith with us. That is obvious and sufficient reason for the only action that he will understand.—I am, etc.,

Canterbury.

R. C. McINTOSH.

Marriage Allowances for Medical Officers

SIR,—Recently questions have been discussed in the House of Commons referring to the allowances payable to married officers. It seems a pity that no reference was made to the following anomaly.

The majority of serving practitioners and dentists, holding only temporary commissions as they do, are not eligible for the extra marriage allowances. This makes them to all intents and purposes the only married officers who do not receive extra allowances under the new rates of pay. I think you will agree that this is a most unfair discrimination, as professional men in the Services hold positions of trust and responsibility that are, to say the least, comparable with those held by other officers.

The increases were made, it is quoted, to offset the present high rents, etc., that married personnel have to pay, and it is felt that these rents cannot under any stretch of the imagination be believed to apply only to regular serving officers. I ask you, therefore, to do your best to publicize this unfortunate state of affairs.—I am, etc.,

London, N.3.

E. J. TRIMMER.

* * The Secretary of the Association writes: It has not yet been decided by the Government whether the recently announced increases in officers' marriage allowances are to apply to National Service officers or not.

Representation of Tuberculosis Workers

SIR,—At a meeting of doctors working in tuberculosis in the Liverpool Region it was recently decided to form a Liverpool Region Tuberculosis Society and to seek representation on the Joint Tuberculosis Council. At a time when the J.T.C. is being consulted about terms and conditions of service for tuberculosis workers it was felt that it was most important that this body should be fully representative of all regions. This view is held by all the sanatorium superintendents and tuberculosis officers in common.

The J.T.C. has replied that it cannot consider our application for six months, as regional representation will involve amending its constitution. It has advised the Liverpool Region to seek representation through the North-Western Tuberculosis Society. Both representatives from the North-Western are from the Manchester Region, and cannot be expected to know anything about conditions in this region. Furthermore, no change in representation could be obtained in this way until the next Annual General Meeting in June, by which time it is expected that negotiations will be completed.

Our Society therefore wishes to issue a strong protest against the decision of the J.T.C. to deny representation to the Liver-

pool Region during this critical period, and to point out the unrepresentative nature of the J.T.C. as at present constituted.—I am, etc.,

WILLIAM D. GRAY,
Hon. Secretary,
Liverpool Region Tuberculosis Society.

The Independence Fund

SIR,—One wonders how many of those doctors who now bewail their fate in the National Health Service supported the Independence Fund of the B.M.A. Is it possible to publish numbers or names in order to show how much tangible support the resistance effort received prior to July 5?—I am, etc.,

Southampton.

V. WESTON.

* * The number of medical men and women who contributed to the Independence Fund was 5,325.—Ed., *B.M.J.*

POINTS FROM LETTERS

Employment of Assistants

Dr. DONALD M. O'CONNOR (Launceston, Cornwall) writes: . . . Dr. W. B. Howell (*Supplement*, Dec. 4, p. 210) states, "If there was one on the pay-roll of a principal on July 5 he must have been sufficiently trained to disqualify him from participating in the scheme as a *trainee* at the present time." This example of the *non sequitur* might well find a place in *Alice in Wonderland* but seems to be out of place as a serious contribution to the *Journal*. . . . Dr. Howell's first paragraph seems to indicate that he failed to read either my letter or the Secretary's footnote with any real attention. In the matter of assuming the role of fairy godmother the Ministry made its promise publicly in April. My contention is that the circular "Remuneration of General Practitioners" should not have contained paragraph 6 at all, or alternatively that it should have been made quite clear that this paragraph, and only this paragraph, was not intended to come into force until some uncertain date after the appointed day. . . .

"Practice Allowance"

Dr. K. HARRY GILL (Eastbourne) writes: The large number of letters appearing in the *B.M.J.* prove widespread dissatisfaction among practitioners with the present rate of remuneration. Would not the dilemma which the profession now finds itself in be solved most satisfactorily, I suggest, by a really substantial "practice allowance," since the expenses of both the large and small practice are virtually the same? The practices with maximum lists are financially secure, but those with small lists far from it, and a sufficient practice allowance would assist them, in my view, more satisfactorily than an all-round capitation fee increase. . . .

Dentists' Incomes

Dr. BEALE H. GIBSON (Bradford-on-Avon) writes: . . . While I have no desire to minimize the good work done by our colleagues, it is surely farcical, to put it mildly, that an average dental income should be in the region of £4,000 per annum gross, as stated by the Minister of Health in a recent speech, while few doctors are able to earn half that amount. The relative responsibility, hours of work, etc., should place medical practitioners far above their dental colleagues for financial consideration. While the latter by working overtime are enabled to augment their incomes indefinitely, the doctor, who can be called upon at any time of the day or night, cannot claim a similar privilege. . . . The B.M.A. should realize that discontent is growing very rapidly among the rank and file, while the word "negotiation" gives rise to acute hyperpnea among most of us.

Buying and Selling Goodwill: Correction

Dr. SIDNEY B. DEPREE (Hove, Sussex) writes: Referring to the *Supplement* of Dec. 4, p. 200, as it is desirable for an information service to be correctly informed, may I presume to point out that the Act has not abolished the buying and selling of the goodwill of practices but only of the goodwill of practices of persons who have enrolled under the National Health Service?

NATIONAL (WAR) FORMULARY

The N.W.F. Committee has decided that the third edition of the *Formulary* shall be amended as follows: Emulsion of Liquid Paraffin B.P.C. shall be deleted and replaced by Emulsion of Liquid Paraffin B.P.; the synonym for Emulsion of Liquid Paraffin and Magnesia shall be deleted. The suffix to Emulsion of Liquid Paraffin with Phenolphthalein shall be deleted and replaced by N.W.F. In the latter two preparations the Emulsion of Liquid Paraffin that will be used will now be the B.P. emulsion. It has been agreed that Jan. 1, 1949, shall be the date on which this amendment will come into operation.

H.M. Forces Appointments

ROYAL NAVY

Acting Surgeon Lieutenant T. T. Chapman to be Surgeon Lieutenant.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Commanders E. I. Pudd, V.R.D., J. O. Claude V.R.D., D. W. Bawtree, V.R.D., W. T. R. Chapman, V.R.D., G. F. S. Parker, V.R.D., R. W. H. Tincker, V.R.D., H. G. Ungley, V.R.D., and A. W. Kendall, V.R.D., have been placed on the Retired List.

Surgeon Lieutenants R. W. B. Scott, J. K. Black, J. L. Elliott, R. R. Dickson, L. B. Cohen, and J. E. Morton to be Surgeon Lieutenant Commanders.

Temporary Surgeon Lieutenants R. D. Nicholson, D. G. Jones, D. M. Forsyth, and C. M. Flood have been transferred to List II of the Permanent R.N.V.R. in the rank of Surgeon Lieutenant.

Temporary Surgeon Lieutenants A. A. Murray and P. Millward have been transferred to List I of the Permanent R.N.V.R., in the rank of Surgeon Lieutenants.

Temporary Acting Surgeon Lieutenants I. M. Ormerod, M. G. D. Davys, M. J. Raftar, E. A. D. Boyd, J. P. R. Richardson, P. W. Rowsell, N. O. Bennett, J. D. Eowe, P. R. Boyd, J. H. S. Pettit, J. C. Whyte, F. M. Milne, W. G. D. Murray, and K. B. M. Crawford to be Temporary Surgeon Lieutenants.

ROYAL ARMY MEDICAL CORPS

Lieutenant Colonel J. T. McConkey, C.B.E., has retired on retired pay and has been granted the honorary rank of Brigadier.

Lieutenant Colonels H. S. Milne, M.C., A. R. Barlas, M.C. Paterson, M.C., H. A. Boyle, T. Parr, and M. P. Power, O.B.E., M.C., have retired on retired pay and have been granted the honorary rank of Colonel.

Lieutenant Colonels D. W. M. Mackenzie and W. G. Harvey have retired on retired pay.

Majors (War Substantive Lieutenant-Colonels) J. J. O'Connell, O.B.E., J. M. Carnow, W. M. Oxley, and J. G. M. A. Brunet to be Lieutenant Colonels.

Majors H. V. D. A. Iles, A. MacLennan, O.B.E., F. E. Buckland, J. H. J. Crosse, O.B.E., J. Boyle, R. Phillipson, O.B.E., R. S. Vine, J. S. Kelleher, and K. H. Clark to be Lieutenant Colonels.

Major J. Duzuid has retired and has been granted the honorary rank of Lieutenant Colonel.

Major A. E. B. Wood, retired and re-employed, has reverted to retired pay on ceasing to be re-employed and has been restored to the rank of Lieutenant-Colonel.

Majors M. White, M.C. and G. A. K. H. Reed, retired pay and re-employed, have reverted to retired pay on account of disability and have been restored to the rank of Lieutenant Colonel.

Major A. T. Frost, O.B.E., retired and re-employed on ceasing to be re-employed has been restored to the rank of Lieutenant-Colonel.

Majors D. A. Ireland and H. H. Atkinson have retired having received a gratuity and have been granted the honorary rank of Lieutenant Colonel (Substituted for the notifications in Supplements to the London Gazette dated Nov. 11, 1947, and Aug. 27, 1948, respectively).

Capain (War Substantive Major) D. W. Moynagh, M.C., to be Major.

Captains (Temporary Majors) J. E. Miller, M.C., and F. Lancelley to be Majors.

Captains G. P. Crean, E. D. H. Williams, J. Irvine, and A. J. Fulthorpe to be Majors.

Captains P. L. G. Cole and D. E. S. Steele, from Short Service Commissions, to be Captains.

Captain M. G. Jackson Smyth, from Short Service Commission, has been appointed to a permanent commission.

Short Service Commission Specialist—Captain R. M. Henderson, from Short Service Commission, to be Captain (Substituted for the notification in a Supplement to the London Gazette dated July 23, 1946.) Captain W. P. Lees has retired on account of disability.

Short Service Commissions—Captains (War Substantive Majors) R. H. Spurrer, J. J. Groome, H. L. Connor, W. L. H. L. Bell, G. G. Black, A. T. MacM. Glen, R. H. Wheeler, G. J. Harrison, G. A. Weir, W. G. McDougall, J. McN. Lockie, and F. Livesay have retired having received a gratuity, and have been granted the honorary rank of Lieutenant-Colonel.

Captains (War Substantive Majors) N. R. Murdoch, P. B. Hanbury, P. J. Geoghegan, N. A. Flaherty, J. Reeve, T. P. O'Brien, V. Bennett, C. G. O'Donoghue, and J. S. Hamilton Gibbs have retired having received a gratuity, and have been granted the honorary rank of Major.

Captains F. D. F. Steede, R. A. Daly, G. M. Barling, J. H. Prain, C. E. Brown, G. W. A. Gordon, C. C. Langford, M. Headlam, E. A. Donegan, T. P. Hawkins, and J. Baxter have retired having received a gratuity, and have been granted the honorary rank of Major.

Capain P. G. McGrath has retired and has been granted the honorary rank of Major.

Captains R. Houston, A. A. Gregory, D. Ann, I. A. Jackson, M.B.E., R. P. Bradshaw, and G. P. Stutley, from Emergency Commissions, to be Captains.

Captains I. W. H. Mansfield, J. C. B. Nesfield, E. M. Rowland, G. G. Sherriff, H. F. L. Gallaher, D. G. Howat, R. A. Hoey, D. S. Toole, I. O. B. Spencer, W. M. McLennan, and F. B. Lake have retired having received a gratuity.

Lieutenants (War Substantive Captains) J. C. Crook and W. J. Irwin from Emergency Commissions, to be Captains.

Lieutenants W. F. Belsham, J. G. P. Power, J. F. F. Rooney, A. W. Morrow, J. L. Kilgour, B. McConkey, E. E. Vella, and K. B. Lazarus to be Captains.

Lieutenants S. A. Biggart and

G. H. Bulow, from Emergency Commissions, to be Lieutenants.
Captain M. A. O'Sullivan, from T.A., to be Lieutenant.

ROYAL AIR FORCE

Group Captain L. Freeman has retired at his own request.
Wing Commanders S. B. S. Smith and T. D. L. Bolan have retired on account of medical unfitness for Air Force Service.

Flight Lieutenants T. Gray, F. S. Krusin, R. O. M. Jones, R. A. Smart, M. W. L. White, J. S. Howitt, G. R. Bedford, and A. C. Camm to be Squadron Leaders.

Flight Lieutenant I. R. Waters has retired at his own request, retaining the rank of Squadron Leader.

P. A. Wilkinson to be Squadron Leader.

To be Flight Lieutenants: H. N. H. Genese, T. A. Evershed, J. A. B. Mounsey, S. E. Cupples, W. R. Lee, T. Gray, I. M. Perkins, F. S. Krusin, and H. A. N. Hamersley.

To be Flight Lieutenants (Temporary): R. C. Rylance, M. Mattinson, G. Clayton, and W. S. Noble.

Flying Officers J. S. Conway, M. L. Montagnon, W. S. Peart, W. D. H. Conacher, P. A. Emerson, D. G. Jones, H. L. Jones, D. A. McGreal, J. Mackintosh, J. F. McMinn, A. McNabb, J. W. B. Matthews, C. P. Newcombe, W. Seright, E. J. S. N. Briggs, T. H. S. Burns, P. J. N. Cox, A. Herschell, J. M. White, S. P. Wrightson, J. H. H. Gibbon, S. P. Bruce, D. F. Coulter, J. L. Crammer, B. D. Grant, J. T. W. Jones, R. T. Jones, J. B. Loudon, J. P. Payne, D. Reid, H. D. White, C. Wood, R. N. Grabowsky-Atherstone, S. M. Hilton, G. A. Humphreys, H. Cohen, W. A. D. Combe, J. K. Craig, D. W. J. Cullingford, A. R. Curtis, D. P. Fitzgerald, J. M. Gill, R. W. Hughes, J. D. Kerr, P. B. Kunkler, P. D. Livingstone, R. M. Powell, J. Parkyn, W. L. Sewell, G. R. B. Whitaker, A. T. Wilson, D. A. Watson, and R. G. H. Salkeld to be Flight Lieutenants.

To be Flying Officers: M. T. F. Carpendale and P. W. Robertson.

To be Flying Officers (Temporary): R. MacG. Aitken, G. G. Allan, H. C. H. Bird, E. I. Boxer, D. H. Brooks, D. Brown, J. Brown, P. P. M. Browne, C. M. Browne, C. A. B. Clemetson, W. H. D. Fairbank, G. Fairclough, J. Findlater, M. E. Glanvill, M. A. Heasman, J. A. Hill, O. E. F. Hodgson, D. A. P. Hunt, L. J. M. Jamieson, J. S. Jenkins, J. D. C. Lyons, R. L. McGhie, D. McD. McKean, A. L. McNab, A. Millar, I. O. Miller, J. B. Moser, A. Muir, K. H. Nickol, J. P. Ommer, G. J. Pack, P. N. Porritt, E. T. Roberts, E. Sherrah-Davies, O. H. Taylor, G. C. Thick, J. P. D. Thomas, I. H. Thomson, A. C. Traill, A. P. Waterson, W. F. Watson, C. B. Whittaker, D. A. Good, C. B. Wynn Parry, N. V. Addison, W. S. A. Allan, J. J. Ashken, A. J. Barr, J. G. S. Buchanan, J. F. Butchart, G. S. Cairness, R. A. Chambers, A. J. Essex-Cater, E. Evans, J. P. Falkingham, J. M. Ferries, R. S. Gillinson, S. Gillis, R. H. Griffith, J. F. Hale, J. A. Howarth, J. G. Inglis, J. A. James, A. F. Johnstone, W. B. Kennedy, R. G. Krause, J. I. Lees, J. D. O. Loudon, I. L. Macfarlane, R. A. Maxwell, J. L. Moffatt, J. E. Murray, W. H. Nisbet, J. G. Parish, P. K. Pybus, D. A. Road, G. Ross, P. R. McH. Scales, O. H. Simms, C. G. W. Sykes, K. P. Williams, M. B. Wingate.

RESERVE OF AIR FORCE OFFICERS

Squadron Leader A. R. Agate has resigned his commission, retaining his rank.

Squadron Leader R. C. H. Tripp has relinquished his commission on appointment to the reconstituted R.A.A.F., retaining the rank of Wing Commander.

ROYAL AUXILIARY AIR FORCE

R. C. H. Tripp to be Flight Lieutenant.

ROYAL AIR FORCE VOLUNTEER RESERVE

Flight Lieutenant J. M. Sword has resigned his commission, retaining the rank of Squadron Leader.

Flight Lieutenants J. M. Whaites, G. J. E. Ansell, R. G. P. Heard, G. R. B. McCarter, and P. R. B. Jones have resigned their commissions, retaining their rank.

Flight Lieutenants R. E. Glenn and T. G. Bradley have relinquished their commissions on account of medical unfitness for Air Force service, retaining their rank.

Flight Lieutenant G. Clayton has relinquished his commission on appointment to the R.A.F.

Flight Lieutenants W. S. Noble, R. C. Rylance, and M. Mattinson have relinquished their commissions on appointment to temporary commissions in the R.A.F.

Flight Lieutenant H. V. Roberts has resigned his commission.

Flying Officer P. Westcombe has relinquished his commission on account of medical unfitness for Air Force service, retaining his rank.

WOMEN'S FORCES

EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

Mary H. Power to be Temporary Flying Officer.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: D. G. Conacher, M.B., A. F. Fowler, M.R.C.S., and R. G. P. Heard, M.B., Medical Officers, Tanganyika; D. Fairley, M.D., Senior Medical Officer, St. Helena; F. C. K. Austin, M.D., District Medical Officer, Windward Islands; R. E. Browne, M.R.C.S., Supernumerary Medical Officer, Leeward Islands; P. M. Yap, M.B., Medical Officer, Hong Kong; M. Zwierz, M.D., Medical Officer, St. Vincent, Windward Islands; M. A. Byer, M.B., Medical Officer of Health, St. Lucia; L. G. Eddy, M.B., D.T.M.&H., Director of Medical Services, British Guiana.

Association Notices

SUTTON COLDFIELD DIVISION

Notice is hereby given by the Council of the Association to all concerned of the formation of a new Sutton Coldfield Division of the Birmingham Branch. The new Division comprises the area of the Municipal Borough of Sutton Coldfield.

CHARLES HILL,
Secretary.

Diary of Central Meetings

JANUARY

12 Wed. Council, 10 a.m.

Branch and Division Meetings to be Held

GUILDFORD DIVISION.—At Royal Surrey County Hospital, Guildford, Tuesday, Jan. 4, 8.30 p.m. Dr. L. S. Michaelis: "Orthopaedic Treatment of Rheumatism."

LEWISHAM DIVISION.—At Lewisham Hospital, 390, High Street, London, S.E., Friday, Jan. 7, 8.30 p.m. Films: G.P. Anaesthetics.

RICHMOND DIVISION.—At Royal Hospital, Richmond, Tuesday, Jan. 4, 9 p.m. Dr. W. D. W. Brooks: "Bronchial Carcinoma."

Meetings of Branches and Divisions

LINCOLN DIVISION

A general meeting of the Division was held on Dec. 7, with Dr. A. M. Maiden in the chair. There were 41 members present. Resolutions from the West Sussex and Huddersfield Divisions were read which suggested that negotiations should be commenced forthwith to increase the capitation fee to 30s. After Dr. Semple had said that the B.M.A. was not entirely to blame for the present situation as the profession had not stood solidly behind them, the chairman asked Dr. Grey Turner (Assistant Secretary) to speak. He emphasized that great differences of opinion existed in different areas: some practitioners were doing much better under the Act, and a few were doing very much worse. A sample survey had shown that many doctors were making more than ever before. On a basis of available general practitioners to the number of population, it was not possible to implement a reduction to 3,000 maximum. The B.M.A. were pressing for payment of full mileage allowance for rural practitioners. Dr. Friskney put in a plea for the rural practitioners.

Dr. Friskney asked for a show of hands by members present to show how many had had a diminution of income greater than 15%. Twelve out of 24 practitioners indicated that their incomes showed this deficiency. Drs. Cheshire and O'Toole emphasized that the change in income was not so great, but the amount of work was enormously increased. On a show of hands, 15 out of 24 G.P.s indicated that the work in their practices had substantially increased since the appointed day. Dr. Sharrard proposed that the Huddersfield resolution be supported, and this was seconded by Dr. Robertson. An amendment was proposed by Dr. Temple and seconded by Dr. Friskney that a substantial increase in mileage payment be added to the resolution. This amended resolution was then carried by 20 votes to 5.

The meeting then considered a resolution from the Winchester Division suggesting that in certain maternity cases a doctor should be permitted to claim the moneys payable by the State and to charge an agreed additional fee. Dr. Semple proposed that the resolution should lie on the table. The proposal was seconded by Dr. Temple and carried unanimously.

The Winchester memorandum on the organization of the B.M.A. was next discussed. The chairman gave a brief review of the B.M.A. organization and emphasized that at present it was impossible to carry any motion if Council was not in favour of it. Drs. Cottrell, A. H. Briggs, Robertson, Friskney, Cheshire, and Grey Turner took part in the ensuing discussion. Dr. Cottrell said that the Organization Committee at Headquarters was discussing this and similar resolutions. Dr. Cheshire thought that any committee representing the present organization could not be the best one to consider a change. Dr. Grey Turner said that the chief problem was how to get through the large agenda at Representative Meetings, and thought the Division should consider if they were prepared to sacrifice their present privilege of direct approach by Divisions to a Representative Meeting. Dr. Semple proposed that they should write to the Winchester Division giving support to the main principle of their Memorandum. This proposal was seconded by Dr. Sharrard and carried without dissent.

The meeting was closed by a vote of thanks to Dr. Grey Turner which was proposed by Dr. Semple and carried with acclamation.

The Minister of Health has made the following appointments to Regional Hospital Boards.—East Anglian: Mr. C. Dudson, former Governor of Peterborough Memorial Hospital and a member of the Executive Committee of the Railway Clerks Association, in succession to Mr. O. Chivers; Col. D. Portway, Master of St. Catharine's Hospital, Cambridge, in succession to Dr. T. S. Hele. Oxford: Sir Henry Clay, Warden of Nuffield College, Oxford, and member of the Board of Governors of the Oxford United Hospitals, in succession to Sir Oliver Franks, now British Ambassador to the United States.

LONDON SATURDAY JANUARY 8 1949

CLINICAL AND SOCIAL PROBLEMS OF EPILEPSY*

BY

F. J. NATTRASS, M.D., F.R.C.P.

Professor of Medicine, University of Durham; Physician, Royal Victoria Infirmary, Newcastle-upon-Tyne

LECTURE II

The Causes of Epilepsy

There are two ways of looking at the problem of epilepsy in an aetiological sense. One is to regard all forms of convulsive attack as epilepsy, which then becomes simply a symptom of many general and nervous diseases: Cobb (1936) lists sixty clinical causes of fits. The other is to reserve the term for an essentially neurogenic disorder in which there is episodic disturbance of cortical function: this would include idiopathic epilepsy, and might reasonably include also symptomatic epilepsy due to primary intracranial disease. It would exclude convulsions due to general circulatory changes, to circulating toxins, or to metabolic poisons. According to this definition it would be correct to speak of cysticercosis epilepsy or traumatic epilepsy, but incorrect to speak of "cardiac epilepsy," "hypoglycaemic epilepsy," or "uraemic epilepsy." This clinical classification seems to me a useful one.

In every case in which an initial diagnosis of epilepsy has been made two further aims should be in the mind of the physician: (1) to determine the part of the brain in which the disturbance starts; (2) to decide the nature of the lesion at that point.

The Anatomical Diagnosis.—Localization of the site of the discharge is clinically precise in local epilepsy of all types and in generalized seizures with consistent focal onset. Lennox and Cobb (1933) instituted an inquiry into the aura or first stage of the fit in 1,359 patients. A similar inquiry was made by Gowers (1901) in 2,013 patients, and it is remarkable to find that the percentage reporting an aura of some kind is almost identical in the two series—namely, 56.2% and 57%. An aura occurred with equal frequency in idiopathic and symptomatic cases, but in only a minority was it of precise localizing significance. Aid in localization is also given by electro-encephalography, and Jasper (Penfield and Erickson, 1941) believes that such records have their chief value in demonstrating or confirming the focal origin of attacks.

The Pathological Diagnosis.—Determination of the site of a discharging lesion or epileptogenic focus, if this is possible, does not of itself, as Hughlings Jackson pointed out, give any information about the nature of the lesion. An initial approach to the problem of the pathological diagnosis is afforded by consideration of the types of cerebral lesion which predominate at different periods of life. Thus in infancy the chief organic cerebral causes of epilepsy are developmental brain defect and birth injury. Such injury

may result from prolonged asphyxia or from cortical laceration, and in these children there are generally other evidences besides epilepsy of diffuse or focal brain injury. It is important to remember that the development of fits originating from the neighbourhood of the injury may be delayed until later childhood or even adult life (Penfield and Erickson, 1941). Acquired cerebral lesions of childhood are often followed by epilepsy. In these, as in birth trauma, there are likely to be focal signs of brain injury, especially hemiplegia. Occurring as a complication of infections of known and unknown nature, and accompanied at the outset by convulsions, the cerebral injury is probably more often due to vascular thrombosis than to encephalitis. After childhood the major organic cerebral causes of epilepsy are head injury, cerebral tumours, and cerebral arteriosclerosis. These have their maximum incidence in early adult life, middle age, and old age respectively.

Significance of Infantile Convulsions

Assessment of the significance of convulsions in an individual child is a clinical problem involving a weighing of the evidence. The presence of signs of pre-existing brain defect or injury is unfavourable. Recurrent attacks occurring at intervals without known exciting cause are strongly suggestive of idiopathic epilepsy, which is likely to continue. Petit mal attacks have the same significance. These considerations apart, an isolated convulsion or a short series of convulsions occurring in early childhood during an acute infective illness, and unaccompanied by persisting evidence of brain damage, need not cause anxiety about the future or call for continued anticonvulsant treatment: the great majority of such children do not develop epilepsy. This is in accordance with the usual belief, but does not justify a tendency to regard infantile convulsions generally as of little moment.

Age of Onset of Idiopathic Epilepsy

A diagnosis of idiopathic epilepsy implies the exclusion so far as is possible of all organic cerebral lesions and in general a tendency to recurrence of attacks without known cause. Idiopathic epilepsy may arise at any age, but does so especially in childhood and youth. An onset in later years is usually stated to be decidedly infrequent. Most textbooks contain warnings such as the following: "It is always well to be suspicious of 'epilepsy' beginning in adult life, for in a majority of such cases the disease is not epilepsy" (Christian, 1942).

Organic disease of the brain which may cause epilepsy is commoner in later life, and therefore epilepsy in such patients is more likely to be due to progressive intracranial disease than in children or adolescents. Nevertheless I see many patients whose fits begin in adult life and continue

*The second Lumleian Lecture, delivered to the Royal College of Physicians, April 15, 1948 (abridged). Lecture I appeared in last week's issue.

without evidence of any structural basis for the attacks. In order to clarify this matter I have made an inquiry into the age of onset in my cases, and secondly into the cause of attacks in the later age groups.

Table I shows the age of onset in 991 cases. While, in accordance with general experience, the highest incidence is in the second decade, it will be noted that 12% showed the first evidence of epilepsy between the ages of 30 and 40 and 17% after the age of 40.

TABLE I.—Age of Onset of Epilepsy in 991 Cases

0-10 years	19%	31-40 years	12%
11-20 "	30%	Over 40 "	17%
21-30 "	22%		

Table II shows a comparison of this series with some previous records.

TABLE II.—Percentage of Cases of Epilepsy with Onset over Age 30

Gowers	Turner	Spratling	Starr	Kraepelin	Paskind	Present Series
9.3	9.8	7.4	12.7	12.8	19.2	29.0

It will be noted that the figures of Paskind (1932) and my own series indicate a markedly higher proportion than the others of patients in whom the first fits occurred after the age of 30. This observer's statistics and my own are comparable because we were both dealing with patients in private practice or in the purely consultative out-patient service of a general hospital. Most if not all of the other assessments were made on patients in institutions or attending special hospitals for epilepsy. These represent a more severe and deteriorated group, and in such patients the age of onset is earlier. Of Paskind's patients 93.5% were in excellent mental health and were engaged in occupations similar to those of the great mass of the population. Tylor Fox (1939) states that there are about 20,000 epileptics in various institutions in this country, and estimates that there are at least 100,000 in the community at large. The extra-mural group is therefore more representative of epileptic patients as a whole.

Table III gives the results of a follow-up, after not less than three years, of 100 cases of epilepsy with onset after the age of 40.

TABLE III.—Follow-up of 100 Cases of Epilepsy with Onset after the Age of 40

Deaths	25
Tumour—proved 8, probable 2	10
Effects of cerebral arteriosclerosis	5
Heart failure	3
Air raid	1
Pancreatic tumour ? hypoglycaemia	1
G.P.I.	1
Cause unknown	4
Improved (fits ceased or diminished)	48
I.S.Q. or worse	27

Of the 25 deaths 10 were due to intracranial tumour and five to cerebral arteriosclerosis. Of the 75 surviving patients none showed on re-examination any symptom or sign of intracranial tumour. Their general condition on the whole was good: most of them were living almost normal lives and were at work. A gratifying number seem to have been much improved by treatment.

Evidences of arterial disease are not conspicuous in these patients. Without doubt cerebral arteriosclerosis may cause epilepsy. But it is not justifiable to assign seizures to this cause merely because the patient is of advanced age. Analysis of blood pressure readings does not seem to indicate the presence of hypertension in these epileptic patients in any greater proportion than in non-epileptic subjects of the same age.

Other evidences of cerebral arteriosclerosis—for example, strokes and mental deterioration—were notably infrequent.

The question arises whether Jacksonian epilepsy is specially suggestive of tumour. Of the 100 patients with onset after the age of 40, 11 are known to have had Jacksonian attacks (Table IV). Of these 8 are dead, the cause being shown.

TABLE IV.—Significance of Jacksonian Epilepsy among 100 Patients

Number known to have Jacksonian attacks	11
Deaths	8
Tumour	3
Cerebral arteriosclerosis	1
G.P.I.	1
Heart failure	2
Unknown	1

The mortality is unexpected, but the point which emerges is that Jacksonian attacks, while revealing the site of the disturbance, give no indication of the nature of the lesion.

One further point of clinical significance is the time of attacks. For the 75 surviving patients this is shown in Table V.

TABLE V.—Time of Epileptic Attacks in 75 Patients over Age 40

Diurnal only	31	Irregular	17
Nocturnal only	27		

A final statistical item invites an approach from another angle—namely, the incidence of epilepsy in a series of intracranial tumours. My colleague G. F. Rowbotham has kindly allowed me to analyse the records of 200 consecutive cases of verified tumour admitted to his clinic in the course of about two years.

TABLE VI
Incidence of Epilepsy in 200 Cases of Intracranial Tumour

Number with fits	56 (28%)
Number with fits at onset	38 (19%)
Grand mal	22
Jacksonian	14
Petit mal	2

Time of Appearance of other Signs of Tumour in 38 Cases with Epilepsy at Onset

Period	No. of Cases	Period	No. of Cases
1-6 months	10	5-6 years	1
6-12 "	8	6-7 "	2
1-2 years	5	7-8 "	1
2-3 "	4	8-10 "	1
3-5 "	5	10-12 "	1

Fits occurred in 28% at some stage. In 19% the patients came under observation because of some type of epileptic attack. In more than half the initial attack was of the grand mal type, in about a third Jacksonian; while in two patients the earliest attacks were of the petit mal variety. Half of these patients with epilepsy at the onset developed other symptoms and signs of intracranial tumour within twelve months. In the remainder such evidence was delayed up to five years, and in isolated cases up to twelve years.

Glioma of a cerebral hemisphere was much the commonest cause of fits; cases which were latent for several years were either astrocytomas or meningiomas. High intracranial pressure *per se* is not an important cause of fits; for example, they are rare in posterior fossa tumours, though these are usually associated with early internal hydrocephalus.

Similar conclusions have been published by a number of observers (Sargent, 1921; Parker, 1930; Dowman and Smith, 1928; Penfield and Erickson, 1941), though the time relationship between epilepsy and other symptoms has not to my mind been sufficiently stressed. The proportion of cases with epilepsy at the onset is considerably lower in most of these reports.

Discussing the causes of epilepsy, Penfield and Erickson (1941), while recognizing that idiopathic seizures may start

at any time, write as follows: "In cases of onset between 35 and 55, the most frequent cause is cerebral neoplasm." "After 55 years the various cerebral lesions produced by abnormality of the cerebral blood vessels become more frequent, though the strong probability of neoplasm must still be remembered." "Idiopathic epilepsy comes on in youth, not in early infancy, and not in middle age or old age."

With reference to these conclusions I would point out that statistics about epilepsy are affected by the tendency for the patients to fall into different groups. There is the broad division between institutional and non-institutional cases. There is also, I think, a process of selection operating in regard to patients sent to neurological surgeons: in a personal communication Penfield agrees with this opinion. I would be the last to minimize the importance of seeking an organic cause in all cases, and especially in patients of tumour-bearing age, but I cannot avoid the conclusion that among epileptics as a whole the largest group must still be classified as idiopathic. When fits are due to tumour careful observation reveals other symptoms and signs within a few months in the majority of cases if these are not already present at the onset of the illness.

Aetiology of Idiopathic Epilepsy

The term "idiopathic" is a deliberate declaration of aetiological ignorance. Without doubt a proportion of cases so classified are due to unrevealed structural causes. Of the remainder it seems probable that the chief cause is an inherited instability of the cortex. But if this is so, then what is inherited is infrequently actual epilepsy; more often a less specific dysrhythmia.

Evidence about heredity is derived primarily from studies of family histories. It has been estimated that 1 in 200 to 300 of the population as a whole has had fits at some time. Among the near relatives of epileptics 1 in 40 to 50 has had fits (Lennox, 1945b). That is to say, seizures are five to six times more frequent in the parents, siblings, and children of epileptics than in the general population. Taking relatives as a whole and not only near relatives, a family history of epilepsy has been obtained by various observers in some 4% of non-epileptics and in from 20 to 30% of epileptics. This figure is less when attacks begin in adult life. Very striking is the finding in a series of identical twins that in 70% of these if epilepsy was present in one twin it was present in the other (Lennox, Gibbs, and Gibbs, 1940).

Further evidence comes from electro-encephalographic records. Soon after the initial discovery of distinctive records in epileptic attacks several observers (Lowenbach, 1939; Strauss *et al.*, 1939) recorded abnormal waves in the relatives of patients. In one study 60% of the near relatives of a group of epileptics were found to have various abnormal rhythms, as compared with 10% of controls with no such family history (Lennox, Gibbs, and Gibbs, 1940). It is important to note, however, that the proportion of relatives whose records showed paroxysmal disturbances of specifically epileptic type was much smaller. Again of special interest is the observation (Lennox, Gibbs, and Gibbs, 1942) of seven pairs of identical twins: one of each pair had epilepsy, and in each instance the other twin showed a significantly abnormal record.

These studies of family trees and electro-encephalograms agree in showing a hereditary predisposition which is very much more frequent than the direct inheritance of epilepsy. It has been suggested that epilepsy results when acquired factors such as trauma or tumour combine with genetic factors. This theory is attractive, but seems to have only a limited application, since in the majority of cases no exciting cause can be found for the onset of overt epilepsy.

Medicinal Treatment

On May 11, 1857 (vide *Lancet* of that date), Sir John Locock presided at a meeting of the Royal Medical and Chirurgical Society of London at which an address on epilepsy was given by Sieveking. In the discussion Locock mentioned that he had been trying treatment by bromide of potassium at the suggestion of an unnamed German physician. The suggestion was made because this medicine had been found to depress sexual activity, and the idea had long been prevalent that masturbation was an important cause of epilepsy. This belief persisted: as late as 1880 a paper was read at the annual meeting of the British Medical Association at Cambridge on the treatment of epilepsy by castration (Temkin, 1945). Bromides in various combinations became the first effective treatment of this disease, and remained unchallenged for fifty years.

Phenobarbitone

Medicinal treatment is now more hopeful than in the past, but rather more complex because several drugs of proved efficacy are available and it is necessary in each case to decide which remedy or combination of remedies is most likely to be successful. Phenobarbitone has very largely replaced bromides because both clinically and experimentally it is a more effective anticonvulsant, is easier to take in tablet form, and is almost free from toxic effects. The dose which can be tolerated without drowsiness varies very much in different individuals. It is generally sufficient to give it morning and night in a dose of $1\frac{1}{2}$ gr. (0.1 g.) for an adult, but this may be pushed considerably higher in some patients if control of attacks is inadequate. Patients who have only nocturnal attacks may take a rather larger dose at night, but it is probably best not to omit altogether a smaller morning dose, because if it is given only once in twenty-four hours there is a tendency for attacks to be postponed to the uncontrolled period. When the optimum dose has been decided it should be maintained with great regularity: if attacks have been absent for three years it may be reduced gradually and finally discontinued. Sudden cessation frequently leads to return of attacks.

"Epanutin"

In an exhaustive series of experiments Merritt and Putnam (1945) found that the most effective anticonvulsant tested was the sodium salt of 5, 5, diphenyl-hydantoin, known in this country under the approved name of soluble phenytoin and "epanutin," and as dilantin sodium in America. A large number of reports have been published since this drug was introduced ten years ago (Parke, Davis and Co., 1945). There is no doubt it is the most powerful anticonvulsant known, and it has the great advantage that in therapeutic doses it has practically no hypnotic effect. It is especially potent in the control of psychomotor attacks. It has not, however, displaced phenobarbitone, because with its use there is a much higher incidence of toxic effects. These are rarely dangerous, but they may be alarming, and the margin between the effective therapeutic dose and the toxic dose is often narrow.

When toxic symptoms occur they usually do so early in treatment, but occasionally they appear after several months. Nausea and vomiting are generally avoided by giving the remedy with meals. Erythematous rashes with fever are infrequent but necessitate withdrawal of the drug, with resumption in gradually increasing doses. The most frequent and disturbing effects are referable to the nervous system, and include nystagmus and diplopia, tremors, and ataxia of upper and lower limbs.

A curious oedema of the gums has been reported with varying frequency in different series. In spite of much work on it the nature of the change is obscure: its incidence is diminished by preliminary removal of oral sepsis, and continued care of the teeth and massage of the gums usually render it unnecessary to discontinue the drug.

No serious blood changes have been reported from the use of epanutin.

The usual minimal effective dose for adults is three capsules (each $1\frac{1}{2}$ gr.: 0.1 g.) daily, one with each of the principal meals.

If a distinct effect is not observed a fourth dose may be added, and further additions may be made in cases under continuous observation. Most British reports on this remedy come from institutions, and therefore concern severe cases and usually those which have failed to respond satisfactorily to phenobarbitone. For less severe cases it is not always necessary to give full doses; furthermore, if the treatment is begun and increased gradually toxic effects are lessened (Pullar-Strecker, 1945).

Both phenobarbitone and epanutin are anticonvulsants and of chief value in the control of major seizures. They are often without effect on petit mal, and indeed epanutin may increase the number of attacks of this type. In cases resistant to either drug alone a combination of the two may prove more effective. Such combined medication is in fact very commonly used, but it is important to realize that if this plan is followed the dosage of each drug should be adequate. There is reason to believe that the action of the two is different: the beneficial effects of the second drug are not obtained unless it is given in sufficient amount to produce an effect by itself, and the toxicity of the one is neither enhanced nor diminished by the other (Blair, 1947).

"Tridione"

The frequent failure of the anticonvulsants to influence petit mal gives importance to the introduction of a drug which has a striking effect on this type of attack and also on the allied akinetic seizures and on epileptic myoclonus. This is 3,5,5-trimethylxazolidine-2,4-dione, or "tridione," and its use for epilepsy is due to Lennox. It has become available in this country only in the past few months, and only one report has yet been published by a British observer (Butter, 1948). I can therefore only speak of it from a very limited personal experience, but it may be useful to mention the main facts as set out in the careful reports from America, where some 10,000 patients are being treated with it. Lennox (1945a, 1947) reported that of 166 patients 31% had been entirely freed of attacks, and in 32% attacks were less than a quarter of their previous number; 83% in all had fewer seizures. Furthermore, in many cases the distinctive paroxysmal spike-and-wave pattern of the electro-encephalogram was restored to normal. He emphasizes that the drug is wrongly described as an anticonvulsant, for not only is it ineffective against convulsive seizures but it may increase these if they already exist.

This remedy is given in capsules of 0.3 g., and the usual dose is three capsules a day for children over 5 years, and four capsules a day for adults, taken with meals. For small children the contents of a capsule may be given with food. The effect on attacks may be immediate, but the maximum effect is usually seen in one to four weeks; the longest period of waiting for relief was six months.

Toxic effects were soon noted. About one in seven patients develops a rash, either a papular rash on the forehead or a morbilliform eruption; if the latter is generalized it is advised that the drug be stopped for a few days and resumed gradually. About one-third of the patients complain of intolerance of bright light; the degree of this symptom, the nature of which is unknown, varies, and it seldom necessitates stoppage of the remedy. No evidence of injury to the retina or optic nerves has been detected. Such toxic effects are rarely serious, but in 1946 two reports (Harrison *et al.*, 1946; Mackay and Gottstein, 1946) were published simultaneously of fatal aplastic anaemia and agranulocytosis due to this drug. It had been given for six months and ten months respectively, when the blood changes appeared suddenly and could not be controlled by any measures. Including these two, Lennox has learnt of four fatal cases. Two further cases have been reported in this country. One (Braithwaite, 1948) had a transient urticarial rash on the 25th day; on the 51st he developed gingivitis and pyrexia. The drug was stopped on the 53rd day, but he died three weeks later with agranulocytosis and an aplastic marrow. The second died, after four weeks' treatment, from exfoliative dermatitis without any blood changes (Kerrin, 1948). These fatalities may reasonably be attributed to idiosyncrasy, and are perhaps no more frequent than with some other drugs, but such drugs are seldom administered for long periods, while remedies for epilepsy have usually to be continued indefinitely. It is therefore important to learn that withdrawal of tridione, unlike phenobarbitone and epanutin, is not followed by an early return of attacks, and in many cases

they have not returned at all. Lennox advises that if attack have been absent for three months the drug should be reduced gradually and finally discontinued. He believes that if monthly blood examinations are done danger can be averted by stopping the drug if the polymorph count falls below 1,600 per c.mm. In 127 patients who had taken tridione for periods up to two years he found that the count fell to this level in 6%, in a cases returning to normal when the drug was stopped. M own experience, though limited to 9 cases, is favourable: in all attacks have been reduced and toxic effects absent except for some complaint of the glare phenomenon. The leucocyte count has not fallen in any case, but tended to rise. In three of these patients attacks have now been absent for three months and the drug is being withdrawn.

Summary of Medicinal Treatment

It may be said that, if a patient suffers from grand mal only, the choice lies between epanutin and phenobarbitone. In young subjects, in whom it is desirable to bring the attacks under control as quickly and certainly as possible because of the danger of mental deterioration, the most powerful remedy epanutin should in my opinion be used provided the necessary observation can be maintained. Alternatively, phenobarbitone may be used in the first instance. If after due observation attacks are not controlled, epanutin should be added gradually without reducing the dose of phenobarbitone. In such cases it is probably best to continue the two drugs together, but reduction in the amount of phenobarbitone may be tried.

When the patient has both grand mal and petit mal control of the former is the more important, but if attacks of the latter are frequent tridione should be used as well as an anticonvulsant. In this event phenobarbitone should be chosen, since epanutin tends to increase petit mal.

For psychomotor attacks epanutin is much the most effective agent. For pure petit mal the evidence I have indicated points to the use of tridione with the appropriate precautions.

Status epilepticus calls for urgent control by full doses of sedative. Probably the safest and most effective method is the intramuscular injection of 5 to 10 ml. of paraldehyde, repeated if necessary. Alternatively, soluble phenobarbitone may be injected in 3-gr. (0.2 g.) doses.

Finally, in this connexion I would quote the words of Blair (1940), that with the remedies now available there are few epileptics who cannot expect reasonable control of their fits, and hope should never be abandoned until these treatments have each been patiently and efficiently tried out.

Surgical Treatment

Epilepsy *per se* is not an indication for surgical intervention. If it can be shown that attacks are arising from a local brain lesion, operation may be justified in the hope of removing the epileptogenic focus. If this is a tumour, relief of fits is only an incidental aim of operation. Non-progressive lesions may be manifested solely by epilepsy: such lesions are meningocerebral scars resulting from traumatic, vascular, or inflammatory changes. Their presence may be suspected because of local epilepsy or generalized epilepsy with consistent focal onset, together with indications from the history of the manner in which they might have originated. Any persistent evidence of impaired function, such as minimal signs of hemiplegia, would of course be decisive evidence of a local lesion. But attacks of both these types occur commonly in idiopathic epilepsy, and a negative exploration may make the patient worse. In these circumstances radiographs after the introduction of air by lumbar puncture provide evidence of the greatest importance (Childe and Penfield, 1944). To this method may now be added the demonstration of a focal lesion by the electro-encephalogram.

Decision about operation if a local lesion has been demonstrated is by no means simple. It has to be remembered that epileptic attacks do not arise directly from an area of cortical fibrosis but are the result of instability produced by the scar in neighbouring but intact cortical cells. Therefore attacks may continue in spite of a clean excision, and anticonvulsant treatment must be maintained. Excision of such an area means replacing one scar by another and possibly converting a discharging lesion into a destroying lesion. In each case the frequency of attacks, the effects of a full trial of medicinal treatment, and the risks of injury by the operation have to be taken into account.

Social Problems of Epilepsy

The social consequences of epilepsy are peculiarly severe, and it is our duty to mitigate them so far as lies in our power. Nothing can alter the fact that a liability to sudden and unpredictable attacks of loss of consciousness or of uncontrolled behaviour is a grave handicap to any human being. In this respect epilepsy is much more serious than any other of the paroxysmal disorders, and this is a reason for a *separateness and not a unity of these disorders*.

Two fears fill the minds of the parents of a child with epilepsy—the fear of accident and the fear of mental deterioration. That dreadful accidents can occur we all know, but when we consider the immense aggregate of fits which occur among epileptics in the community we must recognize that serious accidents from this cause are relatively very few. The danger of mental deterioration when attacks begin in childhood is real enough, but is usually much exaggerated in the parents' thoughts. Though there are exceptions, this danger is on the whole proportionate to the frequency and severity of attacks: the risk is therefore diminished by the improved methods of treatment now available. Children with pure petit mal, and the great majority with only occasional grand mal, are in little danger of mental change. Presentation of these facts is of incalculable value to the parents, and is to be preferred to vague promises and hopes.

The first serious social decisions are concerned with education. Frequent major seizures are incompatible with ordinary school life. Petit mal attacks, even if numerous, are almost devoid of risk and should not prevent attendance at school. Infrequent major seizures should not be a barrier. The welfare of the children as a whole must be the first consideration, but if the attitude of teachers is free of fuss and anxiety the witnessing of an occasional attack by other children does these children no harm. Few if any of the school activities should be denied to the epileptic boy or girl. To exclude games for fear of head injury is to provoke greater risks to the child's physical development and peace of mind. Swimming is more doubtful, and must be under supervision; but each case must be considered on its merits, frequency and time of attacks being all-important. To prohibit cycling may cause much unhappiness and is by no means always necessary. Examinations should be taken in the ordinary way. Nothing must prevent the regular supervision of medicinal treatment.

Interesting studies have been made of University students subject to epilepsy. In one such study of 93 students (Himmler and Raphael, 1944) 76% were classified as of the idiopathic group; the rest had some evidence of cerebral injury or defect: 65% to 70% did creditable work and took up jobs of all kinds, including medicine. Of 70 epileptic students at another University (Lennox, 1946) the number graduating equalled the record for all students.

Such facts have a bearing on the important question of choice of occupation. Essentially a decision depends on the degree to which attacks are controlled by treatment.

Short of complete control, however, infrequent attacks should seldom be held to prevent a young man from adopting the occupation of his choice. Certain callings are clearly unsuitable. They include contact with dangerous machinery, work at heights or in the mines, or any post in which an attack might involve danger to others. It is not in our discretion to give permission for a patient subject to epilepsy to drive a motor vehicle, for this is his own responsibility. The law, being unsatisfactory (Symonds, 1948), is in fact widely evaded.

Medicine, law, the arts, and many office occupations need not be regarded as closed, for there are branches of these which can be pursued with success and safety, though others are barred. For those with no special ambitions more specific advice may be given, and I have been accustomed to suggest work on the land, which is healthy, active, and satisfying, and involves little restriction apart from possible avoidance of agricultural machinery.

As a fact the great majority of adult epileptics outside institutions earn their living in every variety of calling, and many have achieved fame in every walk of life. These people form by far the largest group of all sufferers from epilepsy. They are a relatively stable group and do not deteriorate as the years pass, but rather tend to improve. The more serious cases beginning in childhood have been weeded out. But though they are at work for the most part, they suffer serious social disabilities. Many conceal their liability to fits and go in fear of an attack at work which will lead to loss of their employment.

Hitherto probably the greatest deterrent to the securing of work has been the liability of employers for accidents arising out of and in the course of employment. Replacement of the Workmen's Compensation Act by the National Insurance (Industrial Injuries) Act should greatly assist in the employment of epileptics in common with other partially disabled persons. The need for full use of man-power, as well as an increased sense of social responsibility, led to the Disabled Persons (Employment) Act of 1944, under the provisions of which a proportion of disabled persons must be accepted by all employers of more than twenty people. The Act provides for registration as a means of identifying those who are qualified for its benefits, and responsibility for finding suitable employment is in the hands of Disablement Resettlement Officers (D.R.O.s) working at the Employment Exchanges. For those judged unfit for ordinary employment, work may be found in sheltered workshops maintained under the Act by the Disabled Persons' Employment Corporation: eight of these factories have been established throughout the country and fifty more are planned. Special provision for epileptics has been made in certain of these factories.

Apart from official help, voluntary organizations, including the hospital almoners' service, are ready to assist epileptics to get and keep jobs, and are endeavouring to overcome prejudice and ignorance on the part of employers and the public in regard to this disease. In this country Tylor Fox (1939, 1947), and in America Lennox (Lennox and Cobb, 1942), have in particular been tireless in their efforts to improve the lot of epileptics in the community. The success of all plans depends entirely on the initiative and co-operation of those in medical charge of the patients. We alone know when it is reasonable to ask employers to accept such persons in their factories or offices; school and University authorities look to us for guidance in the difficult decision whether to accept a student or pupil known to be liable to fits. To recommend unsuitable patients is to do harm to them and to epileptics as a whole. No two cases are exactly alike; frequency and character of attacks are clearly the main considerations, but favourable points are

the occurrence of attacks chiefly or solely during sleep or in the early mornings, the existence of a warning long enough to enable the patient to avoid heavy falls, and a satisfactory degree of control by medicinal treatment.

One further social problem is that of marriage. On the basis of the evidence about the heredity of epilepsy formerly noted, the chance of a child of an epileptic also becoming epileptic has been variously estimated as from 1 in 10 to 1 in 40 (Brain, 1926; Lennox, 1945b). The risk of transmission is probably much less still if attacks begin in adult life, or if the patient has no family history of epilepsy; also if attacks are the result of a definite brain injury. A family history in both partners greatly increases the risk. Electrical records of epileptic type in either partner or both partners have probably the same significance. The prospect of producing epileptic children is therefore far less than is generally believed, and this we can conscientiously explain to those concerned. The real risks in marriage are the anxieties and dangers caused in the home and at work by the attacks themselves: these known risks can be calculated and faced. Nevertheless, so great is the dread of epilepsy that many patients decline marriage or refuse to have children. Both decisions are probably wrong, but they are understandable.

I have pleasure in acknowledging the help of successive assistants in following up cases—namely, Drs. H. G. Miller, F. Robertson, R. Mowbray, G. C. Ismay, and J. P. Anderson.

DIABETIC FERTILITY, MATERNAL MORTALITY, AND FOETAL LOSS RATE

BY

J. A. L. GILBERT,* M.D., F.R.C.P.Ed., M.R.C.P.

AND

D. M. DUNLOP, B.A., M.D., F.R.C.P., F.R.C.P.Ed.

(From the Medical Research Council Clinical Endocrinology Research Unit, Edinburgh University)

Fertility

Pregnancy in diabetic women in the pre-insulin era was a rare event. Skipper (1933) credits Bennewitz (1826) with the first recorded case. Amenorrhoea due to uncontrolled diabetes accounted for the low fertility rates of 2–6% quoted by Lecorché (1885), von Noorden (1909), and Skipper (1933). The diabetic control that followed the introduction of insulin in 1923 largely abolished the amenorrhoea and produced a concomitant increase in fertility.

Skipper (1933), reviewing the records of the London Hospital, noted a fertility rate of 15% amongst 177 diabetic women between 1923 and 1931, compared with a rate of 2% amongst 190 comparable diabetic women between 1893 and 1922, while Eastman (1946) observed a fertility rate of 28.6%.

The rate of diabetic to non-diabetic pregnancies admitted to large obstetric hospitals has shown a similar rise. Williams (1909) saw only one pregnant diabetic during his thirteen years in charge of the obstetric service at Johns Hopkins Hospital, and in his review of the literature found only 65 recorded cases, whereas Mengert and Laughlin (1939) quote a ratio of 1 in 276, Barns (1941) 1 in 930, and Eastman (1946) 1 in 282. There were 70 diabetic pregnancies among the 20,438 confinements at the Simpson Memorial Maternity Pavilion of the Royal Infirmary, Edinburgh, between 1943

*This work was carried out during the tenure of a Lund Research Fellowship of the Diabetic Association.

and 1947—a ratio of 1 in 292. Insulin has therefore raised the status of the pregnant diabetic from that of a medical curiosity to one for which adequate provision must be made in any maternity service.

Maternal Mortality

An immediate maternal mortality of between 25 and 30% in diabetic women was associated with pregnancy in the pre-insulin era (Duncan, 1882; Offergeld, 1908; Williams, 1909; and others). The last-named author noted an immediate mortality of 27%, with an additional 23% during the ensuing two years, due to diabetic coma in the majority of cases. The insulin era has been associated with a progressively declining maternal mortality. Reviews of the literature by Skipper (1933) and Kramer (1935) revealed immediate maternal mortalities of 9.3 and 3.4% respectively. A mortality rate of less than 2% was quoted by Lawrence and Oakley (1942). White (1946) reported the loss of only one mother in 271 diabetic pregnancies between 1936 and 1946. Several smaller series of cases reported by Kramer (1935), Brandstrup and Okkels (1938), Shir (1939), Mengert and Laughlin (1939), and others reveal no maternal loss. There was one maternal death among the 70 pregnancies in the 62 diabetic women confined at the Simpson Memorial Maternity Pavilion, Edinburgh, between 1942 and 1947. It is thus apparent that the introduction of insulin has made pregnancy relatively safe for diabetic women.

Foetal Loss

The beneficial effects on the mother from insulin treatment have not been shared by the foetus. Henley (1947), reviewing the literature, noted a foetal loss of 43% in 169 pregnancies during the pre-insulin era, compared with 3.6% in 924 pregnancies since the introduction of insulin. The foetal loss rate in his own series was 55%.

The published figures of the foetal loss rate show considerable disparity. Mengert and Laughlin (1939) and Miller, Hurwitz, and Kuder (1944), considering only the foetal deaths occurring late in pregnancy and the deaths of babies during the neonatal period, found the foetal loss rate to be 18.2 and 23.6% respectively. On the other hand the foetal loss rates reported by Ronsheim (1933), Herrick and Tillman (1938), Barns (1941), and Lawrence and Oakley (1942), covering the whole course of pregnancy and the neonatal period, were 64, 43, 44, and 37% respectively.

Throughout this review of our cases the term "foetal loss rate" is taken to mean the percentage of all pregnancies not resulting in the birth of a baby living for at least 14 days. The term is therefore inclusive of all abortions, miscarriages, intrauterine deaths, stillbirths, and deaths occurring during the first 14 days of the neonatal period.

Using this definition, Table I shows that in spite of medical and obstetric supervision which we hope has been at least not inferior to the average in the country our foetal loss rate during the last five years has been as high as 51.4%.

TABLE I.—*Diabetic Foetal Loss Rate*

Period since Diagnosis of Diabetes	Total No. of Pregnancies	Foetal and Neonatal Loss	Foetal Loss Rate
0-2 years	35	19	54.3%
3 years and over	35	17	48.6%
Total	70	36	51.4%

In comparison with such figures recent results published by White (1946) are striking. This worker uses hormonal therapy to correct abnormal gonadotrophin and pregnanediol levels. She reports foetal loss rates based on

whether these levels are normal or abnormal and on whether patients have been given hormonal treatment of sufficient intensity to correct any abnormality which may exist. She found a foetal loss rate of only 3% when hormonal levels were normal, in comparison with 48% in cases with abnormal levels; but correction of abnormal levels by appropriate therapy resulted in a fall of the foetal loss rate to 10%. Her series, however, does not include abortions before the 24th week of pregnancy, so that her figures are not strictly comparable with our own. Even taking this into account, however, the foetal mortality reported by White is incomparably lower than in any other large series of cases—a result which may well be due to the correction of abnormal hormonal levels in her patients.

Pre-diabetic Foetal Loss: Historical Review

Throughout this article the terms "pre-diabetic" and "diabetic" refer respectively to the phases before and after the diagnosis of diabetes.

Allen (1939) first drew attention to the abnormally high rate of foetal loss occurring in the pre-diabetic period. Mengert and Laughlin (1939) have reported a foetal loss rate of 29.8% in 84 pregnancies during this period. Diabetes developed before the menopause in all their patients. Miller, Hurwitz, and Kuder (1944) have analysed 252 pre-diabetic pregnancies occurring in women developing diabetes during the child-bearing period. Their figures, which are exclusive of abortions and miscarriages, and which therefore include only stillbirths, intrauterine deaths, and neonatal deaths, show a foetal loss of 19.8% during the 20-year pre-diabetic period in comparison with a non-diabetic control rate of 5.4%. The maximum foetal loss rate of 35.4% occurred during the five years immediately before the diagnosis of diabetes and was considerably higher than the foetal loss rate of 23.6% which occurred in the 93 pregnancies among the same group of women after the onset of diabetes. Miller (1945), analysing the obstetric histories of 57 women in whom diabetes was diagnosed after the age of 40, reported an overall pre-diabetic foetal loss of 8.3% rising to 15.8% in the 15 years immediately before the diagnosis of diabetes.

Henley (1947) found a loss of 18% in 160 pre-diabetic pregnancies. His survey covered the pre-diabetic phase of 46 women in whom the disease was diagnosed between the ages of 25 and 69. Dolger and Herzstein (1944) and Herzstein and Dolger (1946) have failed to substantiate these findings. The reports of these workers are based on the pre-diabetic histories of 200 married diabetic women, 94 of whom developed the disease before the age of 45. They conclude that, although there is a significant increase in the foetal loss rate during the five years immediately before the diagnosis of diabetes, yet for pre-diabetic periods of longer duration the rate is not significantly different from that of non-diabetic women. Miller (1946) has challenged this conclusion, and by applying the χ^2 test to their figures has shown the difference between the pre-diabetic foetal loss rate for the 15 years before the onset of diabetes and the control foetal loss rate to be statistically significant. The absence of a uniform definition of foetal loss rate throughout the literature makes precise comparisons of figures impossible.

We have also been impressed by the high rate of foetal loss characterizing the pre-diabetic histories of many of our patients. The present survey deals with the pre-diabetic histories of 165 women attending the diabetic out-patient department of the Royal Infirmary, Edinburgh. All patients were interviewed personally. The group was unselected, and represents 165 consecutive attendances of parous diabetic women at the department.

Present Investigation

Standard Rate of Foetal Loss.—The first step in this investigation consisted in establishing the foetal loss rate in a comparable group of non-diabetic women. This presented many difficulties. The report of the Registrar-General for Scotland is exclusive of abortions and therefore does not give figures of "total" foetal loss according to our definition. Equally unsatisfactory were the histories of patients admitted to local maternity hospitals, since the admission to such institutions is often limited to primiparous patients and to those developing complications of pregnancy. Our diabetic patients are drawn in almost equal proportions from urban and rural districts. Records from the city clinics were consequently not entirely comparable. The standard rate of foetal loss finally chosen for comparison was that of the non-diabetic women attending the Ayr County Maternity Service. This service caters for all pregnancies, normal and abnormal. Further, the patients are drawn from urban centres such as Kilmarnock and from the wide rural districts of Ayr County. Obstetric histories of 1,027 women admitted to the above service in 1942 were analysed. Among the 3,276 pregnancies involved there was a foetal loss of 263 (8%). The components of the foetal loss rate were as follows: abortions and miscarriages, 2.8%; stillbirths, 3.2%; deaths occurring in the first 14 days of the neonatal period, 2%.

Variables Affecting the Foetal Loss Rate.—In the case of non-diabetic women the foetal loss rate might be expected to vary with such factors as the social class and physical condition of the mother, the age of the mother at the time of pregnancy, and the number of previous pregnancies. In a strict analysis it would have been necessary to investigate the foetal loss rate corresponding to each of these variables and to each combination of variables. Such subdivision was, however, impracticable: apart from the difficulty of establishing definitions of social class and physical condition, the numbers involved when such subdivision was undertaken were too small to make statistical conclusions valid. It was assumed, therefore, that these variable factors were "randomized" in our data, and that they were homogeneous when any two rates of foetal loss were compared. The comparisons made above indicate that the foetal loss rate of 8% among non-diabetic women can be used as a satisfactory standard for comparison with the foetal loss rates of the diabetic women concerned in the present survey.

Results

The 165 patients involved were divided into two main groups: (1) insulin group—132 women in whom the administration of insulin was necessary for diabetic control; (2) non-insulin group—33 patients in whom dietary treatment alone was sufficient for diabetic control. Each group was subdivided into: (a) young diabetics—women in whom diabetes was diagnosed before the age of 45; and (b) old diabetics—women in whom diabetes was diagnosed after the age of 45.

TABLE II.—Insulin Group—132 Insulin Patients

Pre-diabetic Period	Total No. of Pregnancies	Foetal and Neonatal Loss	Foetal Loss Rate
0-2 years	20	10	50.0%
3-9 "	58	12	20.7%
10-19 "	129	21	16.3%
20+ "	252	29	11.5%
Total	459	72	15.7%

Insulin Group

Table II shows the pre-diabetic foetal loss rate in the 132 patients who were taking insulin. It will be noted that the overall foetal loss rate of 15.7% is similar to the 18% quoted by Henley and is twice the non-diabetic control rate of 8%. On the whole there is a progressive increase in the foetal loss rate as the time when diabetes was first diagnosed is approached. The foetal loss rate of 11.5% for pre-diabetic periods in excess of 20 years steadily reaches a maximum in

the two years immediately before the diagnosis of diabetes. The foetal loss rate of 50% for the two-year pre-diabetic period in the present survey manifestly represents figures for young diabetics only, the last pregnancy among the old diabetic having occurred not less than four years before the diagnosis of diabetes.

TABLE III.—Young Diabetics—59 Insulin Cases. Foetal Loss Rate According to Pre-diabetic Period

Pre-diabetic Period	Total No. of Pregnancies	Foetal and Neonatal Loss	Foetal Loss Rate
0-2 years	20	10	50.0%
3-9 "	49	10	20.4%
10-19 "	45	9	20.0%
20+ "	10	1	10.0%
Total	124	30	24.2%

Young Diabetics.—Table III shows the pre-diabetic foetal loss rate among 59 young diabetics requiring insulin. It will be noted that the overall foetal loss rate of 24.2% in this group is three times the non-diabetic control rate of 8%—a ratio similar to that observed by Miller, Hurwitz, and Kurden (1944). Their foetal loss rate of 35.4% in the 1-5-year pre-diabetic period is comparable to the 50% during the 0-2-year period in our series, since we found the foetal loss rate of 50% in the 0-2-year phase to be substantially higher than that occurring in the 3-5-year period. We believe that the high foetal loss rate of the immediate pre-diabetic period is the characteristic feature of the pre-diabetic state, to be discussed later.

TABLE IV.—Old Diabetics—73 Insulin Cases. Foetal Loss Rate According to Pre-diabetic Period

Pre-diabetic Period	Total No. of Pregnancies	Foetal and Neonatal Loss	Foetal Loss Rate
3-9 years	9	2	22.2%
10-19 "	84	12	14.3%
20+ "	242	28	11.6%
Total	335	42	12.5%

Old Diabetics.—Table IV shows the pre-diabetic foetal loss rate among 73 old diabetics requiring insulin. An overall loss of 42 (12.5%) occurred in 335 pregnancies. As none of these women had been pregnant for at least four years before the onset of their diabetes, and usually for a much longer time, it is not surprising that they fail to show the very high foetal loss rate characterizing the immediate pre-diabetic phase of the young group of women. Miller (1945) reports similar observations.

TABLE V.—Comparison of Foetal Loss Rate in Insulin and Non-insulin Cases

	Insulin			Non-insulin		
	No. of Patients	No. of Pregnancies	Foetal Loss Rate	No. of Patients	No. of Pregnancies	Foetal Loss Rate
Young diabetics	59	124	24.2%	6	30	26.7%
Old "	73	335	12.5%	27	115	11.3%
Total	132	459	15.7%	33	145	14.5%

Non-insulin Group

The patients requiring only dietary treatment for the control of their diabetes form a small group of 6 young diabetics and 27 old diabetics (Table V). The overall foetal loss rate of 14.5% in this group is not significantly different from the rate of 15.7% in women requiring insulin. Subdivision of the non-insulin group into old and young diabetics revealed foetal loss rates not significantly different from those observed in the insulin group. The similarity in pre-diabetic foetal loss rates of patients requiring insulin and those controlled by dietary treatment alone has been commented on by Herzstein and Dolger (1946). There seems, therefore, to be no relation between the severity of the ensuing diabetes and the pre-diabetic foetal loss rate.

All comparisons of the foetal loss rates between the various groups and the control group discussed above have been subject to the χ^2 test and have been found to be statistically significant.

Discussion

Our observation of an abnormally high foetal loss rate for pre-diabetic periods of up to 20 years confirms the findings of Miller, Hurwitz, and Kuder (1944) and Miller (1945). Our observation of a maximum foetal loss rate among young diabetics in the years immediately before the diagnosis of diabetes still further confirms the findings of these workers.

The similarity of the foetal loss rate in the immediate pre-diabetic phase and in the post-diabetic period raises a doubt whether the immediate pre-diabetic period is in fact pre-diabetic. Herzstein and Dolger (1946) point out that the 0-5-year period is not wholly pre-diabetic, as it may include an unspecified number of undiagnosed diabetics, since it is never easy to determine the exact date of onset of diabetes. We cannot entirely accept this view, for the following reasons: first, in the majority of young diabetics the disease comes on acutely, leaving little doubt about its approximate date of onset; secondly, the features of diabetes, such as glycosuria, polyuria, loss of weight, etc., tend to be aggravated by pregnancy, and it therefore seems unlikely that had clinical diabetes been present during the 0-2-year period it would have been completely overlooked by the obstetrician in the majority of cases; lastly, and most important, Table III shows a significant increase in the foetal loss rate for at least a decade before the diagnosis of diabetes was made, and it is impossible to believe that these young patients were suffering from undiagnosed diabetes for as long as five years.

It seems, therefore, that there is a factor conducive to foetal mortality which may be active for as long as 20 years before the diagnosis of diabetes and very active for the immediately preceding five years. The precise nature of this factor still remains uncertain. It is probable that the factors responsible for the large babies, the high foetal loss rate, and the ensuing maternal diabetes have a common basis in some general metabolic disturbance in the mother, and that the features of clinical diabetes, such as polyuria, glycosuria, thirst, etc., are a very late stage of this metabolic disturbance, an early feature of which is a high foetal loss rate.

Summary

Insulin therapy has increased the fertility of diabetic women and has made pregnancy a relatively safe proceeding for the mother, but has failed to produce a very significant decrease in the foetal mortality rate in diabetic women.

The pre-diabetic obstetric histories of 165 women in whom diabetes was diagnosed between the ages of 25 and 69 have been analysed. The overall pre-diabetic foetal loss rate was twice the non-diabetic control rate.

In those patients in whom diabetes was diagnosed before the age of 45 the pre-diabetic foetal loss rate was three times the non-diabetic control rate. The maximum pre-diabetic foetal loss rate, which was six times the control rate, occurred in the two years immediately before the diagnosis of diabetes was made and was as high as that observed after the onset of clinical diabetes.

In those patients in whom diabetes was diagnosed after the age of 45 the pre-diabetic foetal loss rate, which in this group was one and a half times the non-diabetic control rate, failed to show the dramatic rise immediately before the diagnosis of diabetes observed in the younger group of women.

There appeared to be no relation between the severity of the ensuing diabetes and the pre-diabetic foetal loss rate.

The onset of clinical diabetes may be a late stage in some general metabolic disturbance an early feature of which is a high foetal loss rate.

We are greatly indebted to Mr. George Waugh, F.F.A., A.I.A., F.S.S., for his invaluable work, under the aegis of the Scottish Statistical Research Bureau, in collating and analysing the data in this paper, and to Dr. C. A. Bignold, Medical Officer of Health for Ayr County, for so kindly putting his maternity service records at our disposal.

PREGNANCY COMPLICATED BY DIABETES MELLITUS

BY

H. H. FOURACRE BARNES, F.R.C.S., M.R.C.O.G.*

*Assistant in Obstetric Unit, University College Hospital;
Gynaecological Surgeon, Hospital for Women, Soho
Square; Obstetric and Gynaecological Surgeon,
Queen Mary's Hospital for the East End*

AND

M. E. MORGANS, M.B., M.R.C.P.

Assistant in Medical Unit, University College Hospital

During the past twenty years 45 patients with definite diabetes mellitus have been observed in 58 pregnancies at University College Hospital. The incidence was 1 in 580 deliveries. This high figure is due to the fact that a number of the patients were referred to the Obstetric Unit from the Diabetic Clinic of the hospital. Pregnancy in the diabetic is an infrequent occurrence, and is in part due to the decreased fertility of the diabetic patient and in part to the fact that diabetes is much commoner in women during the latter portion of the child-bearing period, when pregnancy is less frequent (Barnes, 1941).

In 48 of the pregnancies diabetes had been diagnosed and treated by a physician before the onset of the pregnancy. In the remaining 10 pregnancies the diagnosis was made during the pregnancy on the strength of a fasting blood sugar of 130 mg. per 100 ml. or over, a typical blood-sugar curve, and history of diabetic symptoms. The diagnosis was subsequently confirmed after the pregnancy. Hence in approximately one-quarter of the patients pregnancy appeared to unmask the condition of diabetes by precipitating the onset of symptoms or actually to initiate the clinical onset of the disease, which persisted, although usually in a milder form, after the pregnancy.

*Working with a Lund Research Association.

Insulin Requirements During Pregnancy

In this series of 58 pregnancies treatment was with diet alone in 7 cases and with diet and insulin in 51. Of 19 cases under insulin treatment in which the diet remained unchanged throughout the pregnancy and the puerperium (alteration being made only during the labour), nine required more insulin as the pregnancy advanced up to the time of delivery; nine required more up to two to four weeks before delivery, after which a gradual and slight fall in insulin requirements occurred until delivery; and the remaining patient needed no alteration in the insulin dosage throughout pregnancy. Of the 19 patients 17 showed a marked fall in the insulin requirements after delivery; the other two showed no change. These figures support the contention that carbohydrate tolerance usually diminishes as pregnancy advances (Duncan and Fetter, 1934; Skipper, 1933).

It has been thought that any increase in the carbohydrate tolerance acquired during pregnancy was due to the transference of insulin from the foetus to the mother. Skipper (1933) reviewed the evidence and concluded that there was no good reason to believe that such improvement in the carbohydrate tolerance was due to this cause. It should be mentioned that eight of the nine patients who showed this improvement just before delivery were receiving oestrogen therapy at the time, and this may have some significance. Some writers claim that oestrogens improve the glucose tolerance in women developing diabetes at about the menopause (Gessler, Halsted, and Stetson, 1939; Spiegelman, 1940). Lawrence and Madders (1941), using small doses of stilboestrol on a few patients of menopausal age, failed to confirm these findings. In the present series the pregnant diabetics who were treated with oestrogens received ten times the amount of stilboestrol given to the patients of Lawrence and Madders.

The marked and abrupt fall in the insulin requirements after delivery in the majority of patients must be emphasized, for there is the obvious danger that the patient will develop hypoglycaemic coma if this fact is neglected.

Complications of Pregnancy

Hydramnios.—There appears to be a definite and pronounced tendency for the pregnant diabetic to develop hydramnios of the chronic variety with its added complications. In 17 of the pregnancies of this series clinical hydramnios developed—an incidence of 29%.

Coma.—One patient developed diabetic coma in the 33rd week of pregnancy and was successfully treated. Another was admitted with diabetic intoxication at the 29th week. This patient was never in diabetic coma, but her diabetes was exceedingly difficult to balance on account of repeated vomiting. She died a few days after admission. Her blood pressure was 170/100 one day before death, and on the day of death she developed epileptiform convulsions which were not hypoglycaemic in nature. At necropsy there was no evidence of eclampsia or nephritis. In some patients ketosis was precipitated by the onset of urinary infection.

Two patients developed hypoglycaemic coma, and there were others who experienced hypoglycaemic symptoms in the early stage of pregnancy. This may have been related to the development of renal glycosuria, which is often found in normal pregnancy and which may be superimposed on the diabetic condition, or to the prevalence of hyperemesis in early pregnancy or to overdosage with insulin. It cannot be stressed too strongly that the care of the pregnant diabetic should be shared with a physician who will supervise the treatment of the diabetes as soon as it is recognized.

Toxaemia of Late Pregnancy.—There is general agreement that the diabetic is more liable to develop late pregnancy toxaemia than the non-diabetic. The degree of this greater liability varies from three times (Mengert and Laughlin, 1939) to fifty times (White, 1937), according to different observers. On the strict standards for the classification of late pregnancy toxaemia adopted at University College Hospital, and previously outlined (Barns, 1941), there were 25 diabetic pregnancies with this complication. This gives an incidence of 43% as compared with the usual incidence of 35% obtained at University College Hospital for the non-diabetic pregnancies. The toxaemia in 12 of these 25 cases was severe enough to warrant admission to hospital, according to the standards laid down by Browne (1946). Hence the incidence of toxaemia of this severity is 20.7%, which is similar to that in diabetic pregnancies quoted by Herrick and Tillman (1938). The incidence of this severe toxaemia for all patients delivered at University College Hospital during the year 1939 was 5%. White (1935) found that the incidence of eclampsia in the diabetic was nearly 17 times that for the non-diabetic. It would therefore appear that the relative incidence of toxaemia of late pregnancy varies with the standard of severity taken for comparison, and that there is a predisposition for the pregnant diabetic to develop the more severe type of toxaemia.

Prognosis for the Mother

In the pre-insulin era a quarter of the mothers died during delivery or the puerperium and a further quarter died within two years of delivery (Williams, 1909; Offergeld 1908). Diabetic coma was usually responsible for the maternal death. The prognosis for the mother has been considerably improved since the introduction of insulin. Skipper (1933) gave the immediate maternal mortality a 9.3%, with an additional mortality of 3.4% for the next two years. In the present series of 58 pregnancies in 4 diabetic patients there was one immediate death, to which reference has already been made above.

The diabetic is especially liable to infection of one kind or another. Provided that the diabetes is kept under proper control this tendency is reduced to a minimum. There were four pregnancies which were followed by puerperal pyrexia: two were due to urinary infection and one to pleurisy; the fourth was probably due to puerperal sepsis but this was not definitely established by bacteriological investigation.

Walker (1927), like Skipper (1933), is of the opinion that if the diabetes is adequately controlled pregnancy does not produce a permanent increase in the severity of the condition. Observations made in this series of patients support that view. In 34 pregnancies the carbohydrate tolerance as judged by the diet and insulin requirements before and after pregnancy, is known; in 28 (82%) it was unchanged and in six it was decreased. It is to be noted that the onset of the diabetes in these six patients occurred either within a few months of the beginning of the pregnancy or during the pregnancy (two patients).

Prognosis for the Foetus

The foetal mortality for pregnancies complicated by diabetes mellitus has remained persistently high in spite of the great advance made in the treatment of diabetes with insulin. In the pre-insulin era it was 41% (Williams, 1909). Since the introduction of insulin it has remained approximately the same figure.

The obstetrical histories of the patients of the present series show that of 64 diabetic pregnancies 7 ended in abortion—an incidence of 10.9%. As judged from this small series it would appear that the incidence of abortion

in the pregnant diabetic is no greater than that in the non-diabetic (11.8%, Barns, 1947) or that in the woman who subsequently develops diabetes (Barns and Morgans, 1948). The high foetal mortality in the pregnant diabetic is therefore due to some unknown factor or factors which cause the death of the viable foetus and the newborn infant.

The 58 diabetic pregnancies have been divided into a first series of 43 and a second series of 15 because of a radical change in the treatment of the latter. Of the first 43 diabetic pregnancies two resulted in abortion, and in a third case the patient was evacuated (during the war years) whilst pregnant, and lost sight of. There are therefore 40 diabetic pregnancies which were followed throughout pregnancy and which continued beyond the 28th week. Of these 40 pregnancies 18 resulted in live infants, 13 ended in the birth of stillborn or macerated foetuses, and in the remaining 9 neonatal death occurred. The total late foetal mortality is therefore 55%. The cause of this high foetal mortality, consisting of intrauterine death of the viable foetus, stillbirths, and neonatal deaths, is little understood, and none of the hypotheses presented to explain it is wholly satisfactory.

Late pregnancy toxæmia in the mother, with its associated hormonal changes in the serum, has been considered by Smith *et al.* (1944) to be the cause of these foetal catastrophes. In the present series it was found that intrauterine death of the viable foetus did occur without the association of late pregnancy toxæmia, and also that neonatal death was infrequently associated with this complication in the mother. Conversely, Lawrence and Oakley (1942) found that toxæmia could exist without any accompanying foetal catastrophe. They found no support for the view that toxæmia was an important factor in the causation of the high foetal mortality in diabetic pregnancies. The foetal mortality for non-diabetic pregnancies complicated by late pregnancy toxæmia is approximately only half that for diabetic pregnancies with this complication (Barns, 1941). It would therefore appear that late pregnancy toxæmia cannot be regarded as the primary factor in the production of the high foetal mortality. The presence of this complication in the diabetic pregnancy cannot, however, be regarded as unimportant, for it may weigh the scales against a successful outcome.

Coma, diabetic or hypoglycaemic, has been incriminated in the past as a cause of intrauterine death of the viable foetus. Studies of pregnancies in women who subsequently develop diabetes have shown that there is a high foetal mortality in these pre-diabetic pregnancies which increases as the clinical onset of the diabetes is approached (Barns and Morgans, 1948; Miller, 1946). Presumably the factor responsible for these foetal deaths is the same but differs in degree before and after the onset of the diabetes, and it has been suggested that this factor might arise from the anterior pituitary lobe of the mother. It is therefore clear that if such is the case these diabetic complications cannot be the primary cause of the foetal catastrophe, for such occurs with undue frequency before diabetes develops.

Hypoglycaemia in the newborn infant has been suggested as an important cause of the high neonatal death rate in diabetic pregnancies. In six cases of the present series blood-sugar estimations of the newborn were carried out. In no case was the blood-sugar level below the normal range for newborn infants given by Ketteringham and Austin (1938), and in three of the infants so investigated neonatal death occurred. Hypoglycaemia therefore seems unlikely to be the cause of the high neonatal mortality rate, particularly as it is difficult to see why this condition should occur in the infant of the pre-diabetic, in whom there is also a high neonatal mortality rate. The blood-sugar level of the

infant of the diabetic is higher than normal when *in utero* and at birth by virtue of the raised blood sugar of the mother. There is therefore an appreciable drop in the blood sugar to the normal range in the first few hours of life, and this fall is greater than is usual in infants of non-diabetic mothers. It therefore seems reasonable, and at least can do no harm, to give the infant glucose to allow this fall to be accomplished more slowly.

Infants of diabetic mothers are larger than normal; but so, too, are those born during the pre-diabetic period of the mother, hence hyperglycaemia in the mother cannot be the cause of the gigantism, as has been suggested. The abnormal hormone picture of high serum gonadotrophin, low serum oestrin, and diminished pregnandiol excretion sometimes found in these pregnant diabetics has been thought by White *et al.* (1939) to be related to the large size of the infant. This abnormal hormone picture had been claimed by Smith and Smith (1935a, 1935b, 1937, 1940) to precede the onset of, and to accompany, late pregnancy toxæmia. Since, however, the non-diabetic pregnancy with late pregnancy toxæmia does not produce the large infant characteristic of the diabetic mother, it seems unlikely that the abnormal hormone picture is directly related to the production of the large infant. Recently the importance of the pituitary gland in this connexion has been stressed, and it has been suggested that there might be an excess of the growth hormone from the maternal anterior pituitary lobe which causes the infant of the diabetic and the pre-diabetic mother to be large (Barns and Morgans, 1948).

The incidence of congenital defects of the foetus of the diabetic mother is greater than in the non-diabetic. Comyns Berkeley *et al.* (1938) state that the incidence for pregnancies in general is 3%. There were four infants with congenital defects out of the 40 diabetic pregnancies of the first series.

In view of the good results claimed by White (1947) for hormone therapy in the diabetic pregnancies it was decided to treat a series of diabetic pregnancies with oestrogens. The therapy was used on the assumption that oestrogens might act as an anterior pituitary lobe depressant. In the past it has been the custom at University College Hospital to terminate the pregnancy just after the 36th week in order to avoid intrauterine death. Although the infants obtained were large, they were immature. This immaturity cannot be neglected as a factor likely to increase the chances of neonatal death. The first series of 40 diabetic pregnancies were so treated.

The second series of 15 diabetic pregnancies have been treated with oestrogens, and early artificial termination of the pregnancy was avoided in all but the first two cases. There was one stillbirth due to cerebral haemorrhage which occurred in one of the pregnancies terminated early, one intrauterine death, and one neonatal death. Although the series is small, the results suggest that the outlook for the foetus of the pregnant diabetic is improved by the above procedures. It is hoped to present a detailed analysis of these cases in the near future.

Summary

A series of 58 diabetic pregnancies in 45 patients is reviewed.

In the majority of patients the carbohydrate tolerance was found to diminish as pregnancy advanced. In some, however, it increased prior to delivery, and it is possible that oestrogens given therapeutically may have been a factor in this improvement.

The tendency of the pregnant diabetic to develop hydramnios is confirmed.

It was found that hypoglycaemic symptoms and coma tend to occur in early pregnancy, and ketosis and diabetic coma in the latter part of pregnancy.

There is a greater tendency for the diabetic to develop late pregnancy toxæmia than the non-diabetic, and the relative incidence varies with the standard of severity of the toxæmia taken for comparison.

The maternal prognosis is good, and pregnancy does not make the diabetes worse provided that it is well treated.

The late foetal mortality was 55% in a first series of 43 pregnancies. In a second series of 15 pregnancies in which oestrogens were given there were only three deaths. The cause of the foetal mortality is discussed, and it is suggested that the factor affecting the viability of the foetus probably arises in the maternal anterior pituitary lobe. The incidence of abortion does not appear to differ from that for non-diabetic pregnancies, and suggests, first, that diabetes mellitus is not a cause of abortion, and, secondly, that the factor which reduces foetal viability exerts its strongest influence towards the end of pregnancy.

Congenital deformities, gigantism, and hypoglycaemia of the newborn are briefly discussed, and it is suggested that the tendency to gigantism is due to an excess of the growth hormone from the maternal pituitary gland.

We should like to express our gratitude to Professor W. C. W. Nixon, Director of the Obstetric Unit, for his encouragement and permission to make use of the case records of the Obstetric Unit; to Professor H. P. Himsworth, Director of the Medical Unit, for permission to make use of the records of the Diabetic Clinic and for helpful advice; and to Organon Laboratories for the generous supply of stilboestrol dipropionate.

Another step towards closing the wartime gap in the issue of vital statistics by the Registrar-General has been taken with the publication of Part II of the *Statistical Review* for 1943. During that year in England and Wales the improvement in the birth rate following the record low figure in 1941 was maintained, the fall in the still-birth rate continued, and the number of marriages was the lowest for seventeen years. There were 684,334 live births during 1943, representing a birth rate of 16.2 per 1,000 total population. This maintained the improvement seen in 1942, when the corresponding figures were 651,503 and 15.6, and compared favourably with the record low figures of 579,091 and 13.9 for 1941. The birth rate for 1943 was the highest since 1930, when the corresponding figure was 16.3. Later figures showed that the birth rate further increased to 17.7 in 1944, fell to 15.9 in 1945, and again increased to 19.2 in 1946 and 20.6 (provisional) in 1947. Of the live births in 1943, 43,709 or 6.4% were illegitimate compared with 36,467 and 5.6% in 1942 and an average of 4.3% for the ten years 1930-9. In 1945 this proportion was 9.3%; in 1946 it was 6.6%, and in 1947 it was 5.3%.

THE RELATION OF STAPH. PYOGENES TO DENTAL CARIES

BY

E. MATTHEWS, D.D.S., D.I.C., F.D.S.R.C.S.

H. F. ATKINSON, M.Sc., L.D.S.

P. SAUNSBURY, L.D.S.

AND

H. W. CLEGG, M.D., D.P.H.

(From the Turner Dental School and the Department of Bacteriology, University of Manchester)

Appleton (1944), in his review of the bacteria occurring in dental caries, mentioned several workers who have isolated *Staphylococcus aureus* from carious cavities. Among them were Miller, Goadby, Kantorowicz, and Niedergesaeß, but although they had established the presence of this organism in both the superficial and the deep layers of carious cavities it was only rarely and then in small numbers.

Nord (1946) stated that Gottlieb, in a private communication, said he had "discovered the micro-organism causing dental caries to be *Staph. aureus*, and that a perfectly sound tooth in a pure culture of this organism will in two months show caries which cannot be distinguished from true caries."

Gottlieb (1947) headed a paragraph of his book "*Staphylococcus aureus* produces dental caries," and referred to the work of Crawford (1946), who stated that *Staph. aureus* was isolated from carious cavities and that sterile extracted teeth, when placed in a culture of that organism, developed yellow spots and real cavities within two months. Ground sections of these teeth revealed exactly the same picture as that found in naturally carious teeth.

This paper reports the results of a collaborative investigation to test the claims of Gottlieb and Crawford and to find out if the presence of *Staph. aureus* in the mouth could be correlated with caries.

Bacteriological Technique

Material to be examined was incubated for twenty-four hours in a salt-meat medium specially selective for staphylococcus.* A loopful of this culture was spread on a horse-blood agar plate, incubated for twenty-four hours, and then allowed to age on the bench for two or three days so that colonies would have ample time to develop pigment. All varieties of colonies suspected of being staphylococcus were picked off and tested for the production of coagulase. Only "coagulase-positive" strains—i.e., *Staph. pyogenes*—were considered in the results which follow. These strains were all haemolytic. Most of them produced golden-yellow pigment (*Staph. aureus*), but some had white or nearly white colonies (*Staph. albus*). It has been well established that *Staph. pyogenes* nearly always liquefies gelatin and produces toxin and is potentially pathogenic for man. *Staph. pyogenes* should be regarded as including virtually all the strains which, on the basis of colour of colony, were formerly classed as *Staph. aureus*.

It has been shown that by the technique adopted it was usually possible to obtain a nearly pure plate culture of staphylococci when 300 staphylococci were mixed with 1,000,000 other bacteria in 1 ml. of a prepared mixture used as original inoculum. It follows that this method of culture gives no information about the presence or absence

*A full account of work on selective media for staphylococci is being published from the Department of Bacteriology.

of other bacteria, and that the results recorded in this paper refer only to staphylococci.

Experimental

1. *Exposure of Teeth to Cultures of Staph. pyogenes in vitro.*—Sound recently extracted teeth were macroscopically examined to confirm the absence of caries. They were boiled for half an hour and placed in a broth culture of *Staph. pyogenes*. This culture was renewed every two days and maintained at 37° C. Eleven teeth were treated in this way and exposed to the organisms for periods ranging from fifteen days to four months. None of the teeth showed any macroscopical change resembling caries, nor did there appear to be any reduction in the surface hardness of the enamel. Samples of the broth were tested at intervals for the presence of calcium, but none gave a positive result. Ground sections of the teeth made after exposure to the organisms did not reveal any microscopical change resembling caries.

2. *Attempts to Isolate Staph. pyogenes from Carious Cavities.*—Grossly carious teeth were extracted and a swab taken from the surface of the cavity was inoculated into the selective medium. The soft carious material was removed from the cavity with sterile excavators and a little of the carious material from the deep layers was inoculated similarly. Eleven teeth were examined; only one culture (from the surface) yielded *Staph. pyogenes*.

3. *Isolation of Staph. pyogenes from Mouth-washings and Attempts to Correlate its Presence with Caries.*—About 5 ml. of sterile nutrient broth was poured from a test-tube into the patient's mouth and instructions were given to let it wash round all the teeth for about 30 seconds. The broth was then run out of the mouth, through a sterile thistle funnel, back into the original test-tube, and 1 ml. was inoculated without delay into the selective medium. A careful "mirror and probe" examination of the mouth was made to ascertain the existence or absence of clinical caries.

The results of examining a group of 86 school-children aged 5-12 years are summarized in the accompanying Table. In 52 (27%) of 194 examinations caries was present when *Staph. pyogenes* was absent, thus constituting a frank disagreement.

Table Showing Results of Correlating Dental Caries with *Staph. pyogenes* in Mouth-washings

Date of Examination	No. of Children Examined	No. of Children with			
		Caries — <i>Staph.</i> —	Caries — <i>Staph.</i> +	Caries — <i>Staph.</i> —	Caries — <i>Staph.</i> +
16/7/47	86	24	21	22	19
30/7/47	7	—	1	1	5
10/10/47	24	4	3	11	6
17/11/47	28	4	10	4	10
24/10/47	32	4	7	9	12
27/11/47	17	—	—	5	12
Totals	194	36	42	52	64

The remainder may be said to have agreed. There is obvious agreement in 64 examinations (33%) where both were positive and in 36 (19%) where both were negative. There is some doubt in the 42 instances (21%) where caries was absent but staphylococci were present, but it could be argued that these were not in disagreement because the presence of *Staph. pyogenes* might be an indicator of early caries, undetected by the examination employed, which would appear later. Some such cases were in fact demonstrated.

All the children were examined on the first date and as many as possible were re-examined at intervals to test the constancy of findings in individuals and to note any onset of caries. On the whole the results were inconstant. Of 50 children twice examined 20 gave consistent findings, and of 20 examined three times only four were alike on each occasion. The disagreements were nearly always attributable to the bacteriological results; in only a few cases had caries developed during the

interval between examinations. Among the children there were 10 with obvious caries who failed repeatedly to yield *Staph. pyogenes*. Nine children, however, who had no caries at the start but who harboured this organism did develop clinical carious lesions before their final examination.

In view of this last finding and the possibility that the presence of *Staph. pyogenes* in the mouth might be an indicator of incipient or early caries, examination was made of a further series of 17 selected patients who had a small pit or fissure which showed early clinical signs of caries. Nine also had gross carious lesions. Mouth-washings were cultured as before. A sterile probe was pressed firmly into the tiny cavity of the early lesions, care being taken to avoid contact with other tissues, and then used to inoculate the selective medium. Cultures from the deep layers of the gross lesions were also made. The results can be summarized as follows:

	Early Lesions	Gross Lesions	Mouth-washings
No. of examinations	17	9	17
<i>Staph. pyogenes</i> isolated	0	1	12

4. *Control.*—In order to test the possibility that *Staph. pyogenes* found in the mouth-washings might have come from sources other than the inside of the mouth, swabs were taken as indicated below and inoculated into the selective medium. Thirteen of the children referred to in Section 3 were examined, with the following results: (a) Swabs wiped over the lips and adjoining skin: none yielded *Staph. pyogenes*. (b) Swabs taken from the nostrils: three were positive. (c) Of the swabs from the tooth surfaces and gums, those that were positive coincided substantially with the positive mouth-washings.

Discussion

These investigations do not support the view that *Staph. pyogenes* causes dental caries or that its presence in the mouth is an indicator of active or incipient caries.

Exposing boiled teeth to cultures (Section 1) is an arbitrary procedure, under conditions very different from those occurring naturally in the mouth, and a negative result therefore may be regarded as having less significance than a positive one. Nevertheless, teeth were not attacked *in vitro* by *Staph. pyogenes*.

The failure to recover this organism from the lesions in early caries and also from the great majority of cavities in advanced caries using a sensitive selective culture medium is a point of considerable importance (Sections 2 and 4).

The evidence from culturing mouth-washings (Section 3) likewise does not support the association of *Staph. pyogenes* with caries. This organism is often present in the mouth irrespective of the existence of caries. In assessing the results shown in the Table a considerable percentage of examinations may be noted in which there was agreement between clinical findings and results of culture. There were also instances where the presence of *Staph. pyogenes* could be regarded as indicating the impending onset of caries. Against this, however, should be set the instances of frank disagreement, the inconstancy of recovery of *Staph. pyogenes* from individuals on repeated examination, and the number of those who had caries but repeatedly failed to yield *Staph. pyogenes*.

In an earlier series of 25 dental students examined similarly there was possibly suggestive evidence for the idea that *Staph. pyogenes* in the mouth might correlate with the existence of caries, but the further evidence presented here showed that this could not be substantiated.

If *Staph. pyogenes* does not produce caries it is unlikely that other staphylococci will do so. As indicated earlier in this paper, the strains known as *Staph. aureus* would

practically all be included in those designated *pyogenes*. Other staphylococci are less proteolytic and saccharolytic on substrates usually tested in culture, and are less haemolytic and toxigenic. They would therefore be less likely than *Staph. pyogenes* to be concerned in the aetiology of caries.

Conclusion

A combined clinical and bacteriological investigation using a highly sensitive and selective medium for the isolation of *Staph. pyogenes* has failed to reveal an aetiological relationship between this organism and dental caries.

We desire to express our thanks to Mr. R. Bradbury, school dental officer, Borough of Stretford, for arranging and assisting with the examination of the children. We also acknowledge our indebtedness to Professor H. B. Maitland, Director of the Department of Bacteriology.

SENILE DETERIORATION OF THE CENTRAL NERVOUS SYSTEM

A CLINICAL STUDY

BY

TREVOR H. HOWELL, M.R.C.P.Ed.

Lecturer in Problems of Old Age, St. Bartholomew's Hospital;
late Deputy Surgeon, Royal Hospital, Chelsea

Comparatively little has been written about the clinical aspects of neurology in the aged. Even textbooks dealing with old age, such as those of Thewlis (1946) and Stieglitz (1943), are unsatisfactory. The best account at present is that of Macdonald Critchley (1931). He notes the frequent occurrence of several clinical changes. Diminution of objective pain sensation is mentioned, while complaints of subjective pains are said to be common. Progressive loss of vibration sense is stated to be customary, while sluggish pupils, missing superficial reflexes, and weak or absent tendon-jerks are said to be the usual findings. No indication is given, however, of the frequency of these signs or of the age at which they may be expected.

Since the absence of reflexes and alterations of sensation might give rise to the misdiagnosis of neurological lesions, it seemed expedient to examine a series of healthy old people to ascertain what variations are normal. I therefore examined 200 Chelsea pensioners. Most of these men were known to me both personally and professionally, so that considerably more co-operation was forthcoming than might otherwise have been the case. This should add to the credibility of the clinical findings. Among the pensioners examined a small number were found to have neurological lesions previously unrecognized: these were omitted from the series. The results of the clinical examination of the nervous system are described below.

Motor Changes

Tendon Reflexes.—Each case was tested for supinator, triceps, biceps, knee, and ankle jerks. Only 7% of those examined had every reflex present, these being in the younger age groups. The arm-jerks were normal in all men under 70, but the ankle-jerks were not elicited in over half the cases even at this age. In those over 70 there was a definite drop in frequency of all reflexes, but no

further decrease until the age of 85 except in the ankle-jerks (Table I).

TABLE I.—Percentage of Tendon Reflexes Obtained

Age	No	Supinator		Biceps		Triceps		Knee		Ankle	
		R.	L.	R.	L.	R.	L.	R.	L.	R.	L.
65-69	16	100	100	100	100	100	100	87	87	43	38
70-74	57	67	65	88	88	72	79	77	77	32	35
75-79	72	69	68	84	85	84	84	76	76	32	35
80-84	31	68	65	90	90	87	80	80	80	12	12
85-91	9	33	33	66	66	44	55	44	44	22	22
Mean values	..	69	63	86	87	79	79	77	77	29	31

Superficial Reflexes.—Contrary to expectation, the vast majority of plantar responses were normal. Age did not seem to have any bearing on the frequency of abnormality, which was 5%, mainly scattered in the age groups between 70 and 84. There was no difference between the two sides of the body, except in three pensioners. The abdominals, however, were elicited less regularly. The upper quadrants always responded more easily than the lower ones, but there was no constant difference between right and left sides of the belly. The average for all the men was less than 50%, with a drop at 70 years of age and another drop after 85, similar to that found in the deep reflexes (see Table II).

TABLE II.—Superficial Reflexes

Age	No	Abdominals		Plantars	
		R.	L.	R.	L.
65-69	16	100%	100%	100%	95%
70-74	57	63%	75%	96%	94%
75-79	72	54%	49%	96%	96%
80-84	31	51%	52%	89%	87%
85-91	9	47%	45%	100%	100%
		36%	40%		
		61%	48%		
		42%	35%		
		22%	22%		
		0%	6%		

Power.—Power was assessed only roughly in the absence of a dynamometer. The pensioners were graded by strength of grip and by power of flexion and extension at elbow and knee. The results were classified as very good, good, fair, and poor. Loss of strength seemed to develop with increase of age, but this was not universally true in the cases examined, as may be seen in Table III.

TABLE III.—Power in Limbs

Age	No.	Very Good	Good	Fair	Poor
65-69	15	40%	33%	27%	0%
70-74	54	13%	62%	20%	5%
75-79	66	8%	39%	45%	8%
80-84	31	16%	29%	32%	23%
85-91	8	0%	37%	50%	13%
Means :		13%	44%	34%	9%

Sensory Changes

Vibration Sense.—As changes in vibration sense were among the positive findings noted by earlier observers considerable care was taken in testing for this form of sensation. Bony points on both wrists, elbows, shoulders, ankles, knees, shins, and the sacrum were tested. The percentage registering on the sacrum was uniformly small in every age group. More than 90% appreciated vibration on the bones of the upper extremity. Ankles and shins showed perception in over 70% of cases, but the knees appreciated the sensation in just over 50%. The results are shown in Table IV.

TABLE IV.—Percentage Registering Vibration Sense

Age	No.	Wrists		Elbows		Shldrs		Ankles		Shins		Knees		Sacrum
		R.	L.	R.	L.	R.	L.	R.	L.	R.	L.	R.	L.	
65-69 ..	16	100	100	100	100	80	94	87	87	94	87	50	56	12
70-74 ..	57	100	100	100	100	98	98	88	84	81	79	61	67	18
75-79 ..	72	100	100	100	100	90	89	76	73	73	74	51	53	15
80-84 ..	32	97	97	94	97	94	94	62	56	62	44	31	34	10
85-91 ..	9	100	100	100	100	100	100	89	89	67	78	67	78	11
Mean:		99	99	98	99	94	94	79	76	75	72	52	56	15

Joint Sense of Position.—The sense of position of joints was tested by moving the great toe on each side. Three tests were made for each toe after a period of irregular movement. The vast majority of patients showed normal position sense in the feet (Table V).

TABLE V.—Position Sense of Toes

Age	No.	Abnormal Right	Abnormal Left
65-69	16	0%	0.5%
70-74	56	4%	3%
75-79	72	2%	3.5%
80-84	33	1%	1%
85-91	9	0%	0%

Nose-Touching.—To my surprise quite a number of the pensioners were unable to touch their noses accurately when their eyes were closed. The resulting movement was not an intention tremor but a definite dysmetria. This was usually present in both hands, but if one alone was involved the left was the site of occurrence more often than the right. Up to the age of 85, increasing years had no effect on the frequency of the abnormal findings (Table VI).

TABLE VI.—Dysmetria in Touching Nose

Age	No.	Right	Left	Both
65-69	16	0%	25%	19%
70-74	56	9%	14%	20%
75-79	72	11%	14%	18%
80-84	33	6%	15%	21%
85-91	9	0%	0%	44%
Mean:		8%	15%	20%

Rotation of Wrists.—This test showed normal results in four-fifths of the men examined. When there was difficulty in carrying out the movements both wrists were equally at fault. The difficulty appeared to be one of performing an unfamiliar series of muscular exercises and not a cerebellar dysfunction. It is significant that the disability percentage increases steadily with the age of the pensioners tested (Table VII).

TABLE VII.—Difficulty in Wrist Rotation

Age	No.	Defective
65-69	16	0%
70-74	56	4%
75-79	72	25%
80-84	33	33%
85-91	9	44%

Pain, Temperature, and Light Touch.—The results of examination for these sensations were often very hard to interpret. Sometimes pain and temperature sense would be diminished over the same area. Sometimes one would be normal while the other seemed impaired. Touch was involved only half as often as the other sensations. Altogether some 45 patients failed to register 73 sensations between them. The findings were most frequent in the age groups between 70 and 85. The sites of anaesthesia were fairly constant, being almost always on either the shin or the forearm. Usually the inner aspects of the limbs were

involved, but the distribution seemed to follow more of a cord segmental pattern than to conform to any actual superficial nerve area. As it is not possible to summarize this information satisfactorily in the form of a table, let me state that 24% of the men showed impairment of one kind or another. Two-fifths of these did not register pain, two-fifths did not register changes in temperature, and one-fifth could not appreciate light touch. Deep pain sensation was not tested in this examination.

Cranial Nerves

In the examination of the cranial nerves, Nos. 1, 2, and 8 were omitted. The only abnormality detected, apart from changes in the pupils, was an external rectus palsy in two cases. The reactions of the pupils were, however, often abnormal. Sometimes they reacted to light alone, sometimes to accommodation alone, often to neither. A small pupil was more common than a dilated one, but the proportion of either was not great enough to impress the observer.

TABLE VIII.—Percentage of Positive Reactions of the Pupils

Age	No	Light		Accommodation		Neither	
		One	Both	One	Both	One	Both
65-69	16	6	69	0	69	6	12
70-74	57	9	60	0	60	9	25
75-79	72	12	54	7	36	10	24
80-84	32	3	50	0	19	3	44
85-91	9	0	33	0	0	0	67
Mean:		9	54	3	41	8	28

It will be seen from Table VIII that if a response is lost it usually disappears in both pupils. Even at the earliest age group nearly one-third of the men had lost either light or accommodation reaction. The percentage of failures to react increases steadily with age, being more complete in the case of accommodation. A completely inactive pupil was found in two-thirds of those over 85.

Discussion

What is the meaning of the findings recorded above? Let us first try to make a rough statement about the anatomical location of some of the lesions which are indicated. This is not easy, for they appear to be very widely scattered in their distribution.

Judging by the plantar response it would appear that the pyramidal tract is affected in less than 5%, since some of the responses considered abnormal were not of true Babinski type. The frequent absence of the tendon reflexes would suggest possible cord lesions at varying levels. With regard to the sensory losses, it would seem that sensations passing in the lateral spinothalamic tract are lost twice as often as those conducted by the ventral one. A discrepancy appears, however, when the various posterior column sensations are examined. Position sense is normal in the feet of nearly all those examined. Yet vibration is often not felt in the sacrum, ankles, and knees. Dysmetria in the arms is not uncommon. It seems hard to reconcile such findings anatomically. In the same way, the variations in response of the pupils to light and accommodation, tending to become more frequent with advancing years, suggest a progressive but patchy dissolution. It is possible, of course, that some of these lesions may be functional and not organic. For example, it has been shown that the incontinent bladder of old age can be brought under conscious cerebral control by suitable treatment in a number of cases.

The most important result of the investigation, however, is the wide variation of "normal" findings in old age.

Until this is appreciated, non-existent disease of the central nervous system will frequently be suspected or even diagnosed. I have often seen clinical combinations suggesting tabes dorsalis or progressive muscular atrophy in pensioners who were really healthy. Doubtless others have had a similar experience.

Summary

The results of neurological examination in 200 healthy Chelsea pensioners are given.

Absent pupillary reactions, missing tendon-jerks, and superficial reflexes were common motor findings.

Absent vibration sense in sacrum and lower limbs, dysmetria, and patchy analgesia in the forearms and shins were not unusual.

Anatomical location of lesions accounting for such findings was difficult or impossible.

The possibility of misdiagnosis owing to such results of senile deterioration is stressed.

Medical Memoranda

A Case of Tetanus in a Child

Recovery from tetanus, though not unduly uncommon, merits being reported, especially when there are additional interesting and unusual features in the case.

CASE REPORT

A boy aged 8 was admitted at 1.30 p.m. on June 9, 1947. The receiving officer diagnosed "generalized peritonitis? cause." On June 7 the boy fell down and hurt his left leg and his chest. Shortly afterwards he had pain in the abdomen, which became very severe during the night of June 8. There was no nausea or vomiting. The doctor who first saw him found some rigidity and tenderness of the abdomen and diagnosed intestinal obstruction.

On admission the receiving officer observed "absolute rigidity." When I saw the patient, he was flushed and looked ill; pulse 110, temperature 99° F. (37.2° C.), respiration 26, laboured and with working alae nasi. He had marked fetor oris and a furred tongue. The abdomen was a little tender in the left hypochondrium and right iliac fossa; there was no guarding or rigidity. Nothing abnormal found in chest. Several bruises on left leg, recent scratches on front of right chest, and an old healing abrasion over the right knee were seen. He had no neck rigidity or any difficulty in voluntary movement of limbs, but severe pain on attempted movement of trunk. Back very stiff and lumbar muscles tender. Rectal examination revealed nothing abnormal. Blood count within normal limits. Acetone and a trace of sugar were found in the urine.

At 5 p.m. he could not open his mouth wide enough for inspection of the throat, and the attempt produced a painful spasm of the abdominal muscles. On interrogation he remembered some difficulty in opening his mouth the previous evening. A tentative diagnosis of tetanus was suggested, and became evident at 7.15 p.m. with risus sardonicus and typical generalized painful spasm, most pronounced in the abdominal muscles. Treatment was started at 7.30 p.m. with 5 dr. (19 g.) of paraldehyde (in saline) per rectum with 1/200 gr. (0.32 mg.) of atropine subcutaneously. A.T.S. 120,000 units (in two doses) intravenously, and 100,000 units (in three doses) intramuscularly, was given, also 300,000 units of penicillin (in wax). Next day paraldehyde was administered at suitable intervals by the intramuscular route and penicillin was continued. Fluids were taken well and urine was passed. Orthotonus and risus sardonicus were well marked, and occasional generalized spasms were still occurring. Next day the pain became more severe and pethidine had to be given as well as paraldehyde. June 12: trismus still marked, but only one generalized spasm occurred. June 13: general rigidity more pronounced than previously; severe pain in both legs, but no spasms; some cutaneous irritation. June 14: well-marked serum rash; still much pain in abdomen, chest, and legs, but no spasms. June 19: trismus less; general improvement definite; solid food started. June 24: no more pain; rash subsided. On June 29 he got up and on July 5 was discharged home.

The boy received 120,000 units of A.T.S. intravenously and 100,000 units intramuscularly in the six hours following diagnosis, 21 dr. (82 g.) of paraldehyde per rectum in the 18 hours following diagnosis, and 65 ml. of paraldehyde by intramuscular injection adminis-

tered over the next 11 days (average 5.9 ml. a day; maximum actually given in 24 hours was 19 ml.). In addition he received 1,700 mg. of pethidine hydrochloride (including 100 mg. orally) in eight days (average 212.5 mg. a day; maximum actually given in 24 hours, including 50 mg. orally, was 300 mg.). A total of 6,900,000 units of penicillin was administered in 21 days. All this actually entailed 96 needle punctures. The old abrasion on the right knee (which was considered to be the portal entry of the infection rather than the recent scratches on the chest) was dressed for about two days with a hydrogen peroxide dressing.

COMMENT

This case has certain curious features. Most notable is the fact that it presented itself as an acute abdomen, and the first two doctors who saw him diagnosed in succession an acute intestinal obstruction and acute generalized peritonitis. The misleading history of a fall within 48 hours of onset raised the possibility of a ruptured spleen or of an osteomyelitis of the vertebral column. The general appearance and laboured breathing suggested the presence of a pneumonia. Risus sardonicus did not become evident until about 24 hours after the first appearance of trismus (which at no time prevented the boy from speaking distinctly or drinking) and only a very short period before the onset of generalized spasms. Pethidine appeared to give much relief, definitely more than paraldehyde, especially after the appearance of the serum rash (which started four days after the administration of A.T.S. and took 11 days to subside without any special treatment). The patient remained throughout quite bright and co-operative.

I wish to thank Mr. John Scholefield for permission to publish this case, Dr. Dynski-Klein for her help in establishing the diagnosis, and Dr. Rilstone for admitting this child into my ward.

Dystocia after Amputation of Cervix

The Manchester operation for prolapse is carried out so often that it is well to record any untoward results. Hunter (1939) drew attention to the occurrence of dystocia and abortion after the operation and urged conservation of the cervix in the child-bearing period. However, the occasional case does occur in which pregnancy follows extensive operation.

CASE REPORT

In November, 1938, a patient, then aged 40, was treated by anterior and posterior colporrhaphy and amputation of the cervix for procidentia. The cervix was grossly lacerated and hypertrophied, so that the amputation was maximal. There had been four children, all delivered by forceps, and subsequent pregnancy was not anticipated. The cure was complete, and the menstrual cycle was not altered except that the periods were rather scanty.

In September, 1944, the patient's doctor (Harold Hirsch, of Stockport) sought her admission to hospital. He stated that she had been two days in labour, and that although the head was well down in the pelvis he could distinguish no external os on vaginal examination. This examination was repeated in hospital, with the same findings. The head was separated from the examining finger by a thin sheet of muscle in which there seemed to be no aperture. Lower-segment caesarean section was carried out immediately. On exploring the lower pole of the uterine cavity from above no internal os could be found, but there was a definite dimpling where the muscle seemed very thin. After closing the abdomen, vaginal examination was carried out with antiseptic precautions. No blood was present in the vagina, nor could any be expressed. The thin area mentioned above was identified and deliberately perforated with the finger, after which lochia drained freely.

The puerperium was satisfactory, the lochia being normal for a caesarean case—i.e., rather scanty. Vaginal examination was repeated on the 17th day, when again no external os could be identified. Obviously some orifice must have survived the first operation, otherwise neither menstruation nor conception could have occurred. It is suggested that cicatrization had reduced it to a very small aperture, and that the swelling consequent upon the hyper-vascularity of pregnancy had completed the closure.

Reviews

BREAST-FEEDING

Breast Feeding. A Guide to the Natural Feeding of Infants. By F. Charlotte Naish, B.A., M.B., B.Ch. Oxford Medical Publications. (Pp. 151; illustrated. 10s. 6d.) London: Geoffrey Cumberlege. 1948.

Paediatricians look a little uncomfortable, even blush, when the subject of breast-feeding is mentioned. They all proclaim and extol its importance; but it is a complicated problem which has not received sufficient scientific and practical study, and it is therefore sadly mismanaged in practice. In this book Dr. Charlotte Naish gives the fruits of her own study and clinical practice, her aim being to provide general practitioners, midwives, and health visitors with a practical guide in their supervision of breast-feeding. She has succeeded in her aim. Her book is of outstanding merit, and deserves the attention of all who are concerned with the feeding of young infants; it ought to take its place as a standard and authoritative guide to breast-feeding.

The main part of the book is a practical account of breast-feeding in its various phases, from the antenatal preparation for it, throughout the critical stages of its beginning and establishment, to its end in weaning. The author emphasizes the details and technique of management and fully describes them, relating them to the underlying physical and chemical processes at work in the mother and child; she describes these briefly in the first three chapters, and also gives a clear account of the thoughts and feelings of the nursing mother. In this preliminary section the author lays down a principle or working rule that "the baby must be adequately fed, and as much of its food as possible must come from the breast. The younger the baby the more important breast-feeding is." The author regards this rule as of overriding importance, and it governs every part of her practice and almost every page of her book. As a result she says much about and gives instructions for complementary feeding, its indications throughout breast-feeding, and the technique of its administration. There are separate chapters on the succeeding phases of breast-feeding, the first week, the second week, the danger weeks (third and sixth), established breast-feeding, and weaning. Then follow chapters on breast trouble and the contraindications to breast-feeding, with a final and useful chapter on breast-feeding without suckling, where she discusses cases of prematurity, cleft palate, and pyloric stenosis.

The present low standard of practice in breast-feeding is mainly due to downright ignorance, the bad tradition of nursery lore, and the lack of serious clinical study. Dr. Naish's book should do much to remove these obstacles. Based on extensive clinical experience, it is rich in clinical observations. Moreover, it is a constant search for links between the clinical phenomena she describes and the underlying physiological and chemical processes that produce them; and it is this fusion of clinical observations with their hidden causes that determines the techniques of management. Her style is clear, concise, and simple; there is not the slightest difficulty in understanding what the author means in her arguments, explanations, and directions, and she has also at her command a quiet irony which can clear the ground of debate like a stick of dynamite. This is an excellent and admirable book. It should serve its immediate purpose in raising the standard of practice in breast-feeding. It ought also to call the attention of physicians and physiologists to a rich and comparatively unworked field of clinical and scientific study—human lactation and infant digestion.

CHARLES MCNEIL.

GROWTH OF THE MIND

Emotional Problems of Living. By O. Spurgeon English, M.D., and Gerald H. J. Pearson, M.D. (Pp. 438. 16s.) London: George Allen and Unwin. 1947.

To describe the dynamics of the mind to the ordinary intelligent reader is as difficult as describing the structure of the atom without using mathematics. The former seems easier,

because all people are in daily touch with mental problems in themselves and in others, but the processes involved in the development of mental patterns in normal character and in neurosis can be clearly understood and accepted only through a first-hand knowledge of the technique of psycho-analysis as well as its formulated doctrines and hypotheses. Nevertheless, it is possible to convey much information on mental development which can be of use to students, teachers, and nurses. The authors have attempted to do this—with considerable success—using the Freudian doctrine of emotional development from babyhood onwards.

In fairly simple language they take the reader through an account of the various stages of instinctual development in so far as it is basic to the structure of the ego and the unconscious. They describe the vicissitudes of the instincts in the oral, anal, and phallic stages, then through the latent period to adolescence. They write with great care and simplicity and include short illustrative case histories. Those phases are rather rigidly distinguished, which is not the case in reality, for they interpenetrate one another. Furthermore, they do not emphasize enough the role of ego development in the light of the conflict between impulse and conscience, nor the fact that most of these processes are strictly unconscious in their dynamic relations. They do not discuss Melanie Klein's work on the early formation of the conscience and the development of infantile depression, despite its controversial character. The book is such easy and entertaining reading that the novice and the unwary may be easily swept away; it is a big book, and so readable that they may come away too easily instructed in the most difficult of all human problems.

EMANUEL MILLER.

SURGICAL UROLOGY

Surgical Urology. In two volumes. By Dr. G. de Illyés, Professor of Urology and Director of the Clinic of Urology in the Hungarian Royal Péter Pázmány University, Budapest. (Pp. 679; 391 illustrations. 63s.) London: Constable and Co., Ltd. 1948 (1942).

Professor G. de Illyés is a well-known Continental urologist and this book is the outcome of his long personal experience. Volume 1 is divided into a general and a special part. In the former the author discusses symptomatology, methods of examination, and the special instruments used in urology, and in the latter diseases of the kidneys. In Volume 2 he considers the rest of the genito-urinary tract and ends with an interesting chapter on disturbances of sexual function. An index for both volumes is included. The book is profusely illustrated by 391 figures, many of which are in colour; it is clearly printed and well bound, and the text is enriched by descriptions of individual cases to emphasize important facts. The chapters on the kidney and urethra are particularly good, though we do not agree with all the author's views.

This work first appeared in 1942, but the war delayed its publication in England until now; as a result, the author does not entirely fulfil his wish "to present urology in its present advanced stage of development." He does not discuss the most recent advances in urology and describes the sulphonamides (which are not indexed) as a new drug, and their efficacy in the treatment of urological infections is left undecided. He has tried to make the book encyclopaedic in scope and has therefore had to expound some subjects briefly. It would be an advantage to have details of how to carry out transplantation of the ureters into the colon. Diagrams illustrating operative technique might be more plentiful throughout. In the description of suprapubic removal of bladder papillomata we find no mention of protecting the wound surfaces by towels soaked in antiseptic (e.g., silver nitrate) to prevent implantation metastases.

Nevertheless, in spite of these criticisms, the work represents the results of enormous labour in clinical observation and surgical achievement, and the author is to be congratulated on the successful accomplishment of his task. If a new edition is prepared and the most recent advances in urology added, together with a bibliography and an index at the end of each volume, it could be wholeheartedly recommended and would find a permanent place in our reference libraries.

DAVID AIKEN.

BRITISH HOSPITALS

British Hospitals. By A. G. L. Ives. (Pp. 50; with 4 plates in colour and 26 illustrations in black and white. 5s.) London: Collins. 1948.

Mr. Ives's contribution to the series "Britain in Pictures: the British People in Pictures" is well worthy of its place in this deservedly popular set of volumes. The story is felicitously told and the illustrations illuminate the text. In fifty pages he covers the history of hospitals from A.D. 600 to 1948. He uses examples surviving in our midst to bring alive the compassionate spirit imbuing those who founded and those who worked in them; a spirit that waxed and waned, but always survived vicissitudes of national and social upheaval; an inspiration the author hopes and believes will persist even after the transformation recently undergone.

After a storied chapter on the mediaeval scene, with Christian piety as the motive force behind the monastic foundations, he passes on to discuss the royal hospitals and the dawn of scientific medicine; thence the eighteenth century and the spate of voluntary hospitals, listing twenty-eight in the provinces built between 1736 and 1798, besides those in London. He naturally makes much of the Nightingale era, and does not forget the great service of John Howard in for ever harping on cleanliness. There is then a chapter on "The Turn of the Century," with mention of Osler's textbook, the coming of x rays, the development of bacteriology, the realization of the social aspects of medicine, the advent of the almoner, and the establishment of the King's Fund. Then follows a judicious appreciation of the conditions and circumstances that led up to a general recognition of the need for a unified hospital system and of the stages which culminated in the National Health Service. The frontispiece is a fine initial from the illuminated cartulary of St. Bartholomew's; there are pictures by Anna Zinkeisen, Felix Topolski, Edward Ardizzone, and many reproductions of old pictures and engravings. This is quite a fascinating story for the general reader, and there is a lot, too, that will be new to many who thought they knew all about hospitals.

E. ROCK CARLING.

THE PATIENT'S VIEW

Taking the Cme. By Robert G. Lovell, M.D. (Pp. 93; illustrated. 52 or 10s.) New York and London: The Macmillan Company. 1948.

This book, written by an ex-patient, is primarily intended to be handed to the newly admitted patient to a sanatorium so that he shall learn the nature and purpose of what lies ahead of him. I accordingly tried it out on a number of sanatorium patients and asked them what they thought of it. Unanimously they condemned it as a futile attempt to convey in two hours' reading what can be learned and understood only by being *lived through* for weeks and months: "As misleading as programme notes on an unfamiliar piece of music—although perhaps factually accurate," said one. "It tells you nothing that you don't pick up all in good time from doctors, nurses, and other patients," said another, adding, "Surely if anyone is curious enough to want to read the subject up he would want something a bit meatier." "Isn't it a bit optimistic?" asked yet another with feeling. "There's no mention whatever of failed A.P.s, fluid, and similar disappointments that seem to be more the rule than the exception during the course of treatment."

Apart from perpetuating the classical misconception that in lateral decubitus the lower lung does less work than the upper, the book is incontrovertibly accurate—as far as it goes. Unfortunately for us, it is only too evidently written for the average patient in a far-off happy land where dire shortage of nursing and domestic staff does not discourage (if not positively preclude) his ringing a bell whenever he wants a book from his bedside table—rather than raise his shoulders from the bed. The text is enlivened with six line drawings—one showing cross-sections of the chest, one showing plan and elevation of a very useful reading rack, and four that are more facetious. There are also appendices on "Leisure Time Reading," "Listening to Classical Music," and on playing that engrossing paper-game of "Battleships."

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

The W. H. Ross Foundation (Scotland) for the Study of Prevention of Blindness. (Pp. 236. 3s.) London: University of London Press. 1948.

A history of the Foundation, and papers on research carried out under its auspices or at its request.

Tramp Royal. By R. MacMahon. (Pp. 315. 10s. 6d.) London: John Langdon. 1948.

The travels of a doctor to remote countries.

Osteoperiostitis Tuberculosa y Sifilitica. By V. B. Olives. (Pp. 403. No price.) Barcelona: Ediciones Byp. 1948.

A monograph on the pathology, diagnosis, and treatment.

Études Chimiques sur la Tuberculose. Edited by J. Paraf. (Pp. 130. 300 francs.) Paris: L'Expansion Scientifique. 1948.

A collection of papers reviewing work with antibiotics and chemotherapeutic agents.

La Mesure du Rendement Circulatoire. By A. H. Israel and C. H. Rendu. (Pp. 75. 200 francs.) Paris: L'Expansion Scientifique. 1948.

The authors propose a formula for determining circulatory efficiency from the blood pressure and pulse rate.

Abhandlungen der Deutschen Akademie der Wissenschaften zu Berlin. By H. Nachtsheim and H. Klein. No. 5. (Pp. 71. M. 750.) Berlin: Akademie. 1948.

This number contains a monograph on erythroblastosis foetalis.

Estudio Clinico del Enfisema Pulmonar. By J. A. Sciuto. (Pp. 164. No price.) Montevideo: Rosgal. 1948.

A monograph on the pathology, diagnosis, and treatment of pulmonary emphysema.

Leitfaden der bakteriologischen Trinkwasseruntersuchung. By H. Beger. 2nd ed. (Pp. 122. M. 6.60.) Berlin: Urban and Schwarzenberg. 1948.

A short account of the bacteriological investigation of water.

Therapeutisches Taschenbuch. Edited by G. Ruepp. (Pp. 394. 12 Swiss francs.) Berne: Hans Huber. 1948.

A summary of therapeutics for students and house-men.

Synopsis of Physiology. By A. Rendle Short, B.Sc., M.D., F.R.C.S., and others. 4th ed. (Pp. 346. 20s.) Bristol: John Wright. 1948.

A summary intended chiefly for medical students.

Human Embryology and Morphology. By Sir Arthur Keith. 6th ed. (Pp. 690. 40s.) London: Edward Arnold. 1948.

The text has been revised for this edition and many new references have been added.

Das Gesundheitswesen in der Bauplanung Berlins. By P. Vogler and G. Hassenpflug. (Pp. 95. No price.) Berlin: Werner Saenger. 1948.

Public health statistics and maps.

Le Fond d'Oeil des Hypertendus et des Cyanoses. By D. Routier. (Pp. 100. 1,350 francs.) Paris: Masson. 1947.

Annotated illustrations of the ophthalmoscopic appearances.

Contemporary Religious Jurisprudence. By I. H. Rubenstein. (Pp. 120. \$2.50.) Chicago: Waldain Press. 1948.

Discusses the American law in relation to faith healing, fortune telling, and pacifism.

Chirurgie Moderne de la Hanche. By R. Charry. (Pp. 316. 1,340 francs.) Paris: G. Doin. 1948.

An illustrated practical manual on the surgery of the hip-joint.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 8 1949

EPILEPSY

During the last 25 years great additions have been made to our understanding of epilepsy, but there is perhaps no other field of medicine where so large an increase of knowledge has left so many problems still unsolved. This may be, at least in part, because the accumulation of new facts has outrun our capacity to interpret them. The Lumleian Lectures delivered by Dr. F. J. Nattrass and published in this and the previous issue of the *Journal* are therefore timely, for he has made a wide survey of a topic which is of importance to workers in many departments of medicine.

These two lectures raise many questions of absorbing interest. One of the most fundamental is the relationship between consciousness and the functions of the brain. Why does a patient lose consciousness in one kind of epileptic attack and not in another, and what, if any, is the connexion between loss of consciousness and cerebral dysrhythmia? Many neurologists have believed that there are one or more localized areas in the brain disturbance of which causes loss of consciousness. The interpretation of clinical experience by means of electro-encephalography certainly affords some support for such a view. Adrian¹ has pointed out that electro-encephalography shows that in some epileptics considerable areas of the cerebral cortex may be involved in an abnormal rhythmical activity for some time before or after the attack in which consciousness is lost. "That the mind can still function with abnormal waves in much of the cortex," Adrian says, "is not more remarkable than that it can still function when half the cortex is giving the regular beat of the α rhythm or when a large part is removed by the neurosurgeon. What seems to be necessary is that some part of the cortex should still be free to react to the incoming messages from the sense organs and to those handed on from other parts of the brain." We may perhaps infer from this that if a cerebral dysrhythmia is to produce loss of consciousness primarily by disturbing the functions of the cerebral cortex it must be extremely widespread, and such a disturbance, affecting in its course the motor areas, will cause a generalized convulsion, or in other words will produce the clinical picture of grand mal. Clearly, if this view is correct, there must be some other explanation of epileptic attacks characterized almost exclusively by loss of consciousness such as petit mal, or by loss of consciousness accompanied by a sudden fall, as in akinetic epilepsy or what are sometimes called "drop attacks." Again, it is evident that the physiological disturbance is not identical in petit mal and in akinetic epilepsy. In akinetic epilepsy the loss of con-

sciousness may be so brief as to be demonstrable only by the most careful questioning of the patient, for it may be limited to the period of the fall itself. This contrast between the tolerance which the cerebral cortex shows to widespread electrical disturbances in dysrhythmia of the grand mal type and the sudden short and selective loss of consciousness in petit mal and akinetic epilepsy suggests that there must be areas of the brain especially intimately associated with consciousness, and it is tempting to suppose that these areas may be functionally related to the recently discovered system of suppressor bands, from which electrical stimuli evoke a widespread suppression of cortical activity.

This again raises the much-discussed question of the relationship between epilepsy and narcolepsy. Dr. Nattrass would separate the two decisively on clinical grounds, and there is no doubt that as a rule narcolepsy, whether or not accompanied by cataplexy, can be distinguished without any difficulty from epilepsy. Nevertheless there appear to be intermediate states in which the distinction is more difficult. Loss of consciousness is common to both narcolepsy and many forms of epilepsy; similarly, loss of muscular power and tone is common to cataplexy and akinetic epilepsy. The tempo of the disturbance is different, and this may be nosologically important, but the anatomical pathways and physiological functions are surely akin. From the patient's point of view the differences may well be much more significant than the resemblances, but the neurophysiologist may find that each will illuminate the other.

Hughlings Jackson's division of the symptoms of lesions of the nervous system into the negative phenomena of loss of function and the positive phenomena produced by functions released from higher control was a fertilizing idea of the utmost value in the development of neurological thought, but recent advances in our knowledge of epilepsy show its limitations. Can what has been termed a "discharging lesion" be explained entirely as a manifestation of the disappearance of higher control? And is there no place, between functions lost and functions released, for the conception of a distortion of activity? In any case epilepsy is a disruptive and disintegrating influence, for its positive manifestations occur at a comparatively low level of nervous organization. The epileptic convulsion does not consist of co-ordinated movements: these depend upon combinations of neurones too highly organized to be susceptible to stimulation by a method as coarse as an epileptic dysrhythmia.

For all our new knowledge of cortical electronics the essential nature of epilepsy still eludes us. Why does the synchronous electrical discharge occur? Electrical convulsant therapy has shown, what indeed had been stated on theoretical grounds before, that anyone will have an epileptic fit if appropriately stimulated. Nevertheless, the technique of the electrically induced convulsion has also shown that individuals vary greatly in their susceptibility to epilepsy. This fact, of course, was well known to clinicians. A brain injury or a cerebral tumour will induce fits in one person but not in another, and this difference does not appear to depend upon differences in the nature or

¹ Adrian, E. D., *The Physical Background of Perception*, p. 79. Oxford, 1947.

situation of the lesion. It has been shown statistically, however, that it does depend, to some extent at least, upon heredity. Sufferers from traumatic epilepsy, for example, have a much higher incidence of epilepsy among their relations than controls, and many investigations have shown that from one-quarter to one-third of all patients with idiopathic epilepsy have epileptic relatives. But we do not know what constitutes the hereditary predisposition, nor even in what part of the body to search for it. Perhaps, during recent years, students of epilepsy have been too much preoccupied with the nervous system. Humoral factors have been studied in the past without much result, yet they still force themselves upon the attention of every neurologist. Why do so many female epileptics have fits predominantly, or even exclusively, at their menstrual periods? Why does hydration tend to precipitate attacks and dehydration to diminish their frequency? How does the blood-sugar level influence the incidence of convulsions, and to what is the benefit of a ketogenic diet due? These and many similar biochemical questions illustrate the practical and theoretical importance of metabolic factors. Moreover, all our effective therapeutic agents, being chemical, must be made humoral before they can act. All that we have learned about epilepsy in recent years can still be fairly described as a knowledge of what happens when things go wrong. We have been elaborately and successfully recording the speed of a galloping horse that has escaped from the stable door. All our pharmacological remedies are at best little more than strings with which we tie up the door, and which the horse from time to time breaks. But the door has a lock, and we have still to find the key.

DIABETES AND PREGNANCY

Before 1921 the occurrence of pregnancy in a diabetic woman was a medical curiosity; in those days amenorrhoea was the general rule among such women, as indeed it still is while the diabetes is uncontrolled. The diabetic woman who did succeed in becoming pregnant ran a serious risk of death during the pregnancy, during labour, or in the following year or two: overall maternal mortality figures of 50% have been recorded. The foetal mortality was also high, not far short of 50% for the entire pregnancy and neonatal period. The discovery of insulin by Banting and Best in 1921 and its application to the control of diabetes mellitus has had a remarkable influence on the fertility of diabetic women and on their maternal mortality. Diabetes is no longer a rare complication of pregnancy, or, from the physician's point of view, pregnancy a rare complication of diabetes, and with proper control the maternal mortality has been reduced to about 1 or 2%. On the other hand, to quote from the paper by Dr. J. A. L. Gilbert and Professor D. M. Dunlop which appears elsewhere in this issue, "In spite of the most stringent medical and obstetric supervision our foetal loss rate during the last five years has been as high as 51.4%." This figure, which agrees with those of many other authors, including Mr. H. H. Fouracre Barns and Dr. M. E. Morgans, whose paper on this subject is also published

in this issue of the *Journal*, makes it painfully evident that control of the diabetes with insulin and diet has no influence whatever on the foetal mortality.

Control of the diabetes itself during pregnancy is now for practical purposes largely a solved problem, and the fact that different regimes based upon differing conceptions of the changes in carbohydrate metabolism during pregnancy all produce satisfactory results so far as maternal mortality is concerned indicates that close co-operation between physician and obstetrician is all-important—a point stressed by Barns and Morgans. How to improve the foetal mortality, then, is the pressing problem, and the solution of this is still awaited.

The high rate of foetal loss found in the pregnancies of women who subsequently develop diabetes—becoming increasingly obvious as the interval between pregnancy and the onset of the diabetes shortens—was first observed by Allen¹ in 1939 and has since been reported by several other authors.²⁻⁴ Gilbert and Dunlop publish figures which are in close agreement with these writers. In the pre-diabetic as well as the diabetic period this high foetal mortality is caused by an excess of late intrauterine and neonatal deaths, the abortion rate having been found by Barns and Morgans to be essentially the same in non-diabetic, pre-diabetic, and diabetic women. It is clear, then, that neither the hyperglycaemia nor the ketosis of diabetes can be held to account for the adverse effects on the foetus, since the foetal death rate is high before the diabetes makes its presence clinically detectable, while proper control of the diabetes does not reduce it. On the other hand, there is general agreement that the incidence of toxæmia of late pregnancy is significantly increased in diabetes, in spite of adequate control of the latter. Smith and his colleagues⁵ consider that the hormonal changes in the serum which they believe to take place even before the onset of toxæmia may be responsible for the foetal catastrophes. On the supposition that the harm is done by a lowering of the blood oestrogen and progesterone White⁶ has treated a series of some 300 consecutive diabetic pregnant women with oestrogens and progesterone and has obtained 90% foetal survival (excluding deaths before the period of viability).

This striking success has not yet been confirmed, nor are the premises upon which the method of treatment is based generally accepted, though in fairness to Smith and his colleagues it must be admitted that their researches have never been properly repeated by other observers. There is no doubt, for example, that intrauterine death of the viable foetus can occur in the absence of late pregnancy toxæmia, while, conversely, Lawrence and Oakley⁷ found that toxæmia did not necessarily cause foetal death. Palmer and his colleagues⁸ have recently treated 42 consecutive cases of pregnant diabetic women along the lines advised by White and reported a foetal survival in 36 cases of 81.3%,

compared with 60% for a previous group of 41 patients not treated with stilboestrol and progesterone. When, however, the χ^2 test is applied to these figures a value of 2.762 is obtained, which means that the difference between the treated and untreated groups could have occurred in random sampling more frequently than once in 20 times, so that the significance of the reported difference is in some doubt.

Foetuses from diabetic mothers have a marked tendency to be overweight; that this is not the result of maternal hyperglycaemia is shown by the fact that the same tendency is seen during the pre-diabetic period, while control of the maternal diabetes does not decrease the mean weight of the foetuses. It has been suggested by White and her colleagues⁹ that the abnormal hormonal levels in the blood already mentioned might be responsible for the large size of the foetus; it is well known, however, that late pregnancy toxæmia in non-diabetic mothers is associated with underweight rather than overweight babies, so that this explanation seems unlikely. In seeking a more plausible theory to account for the observed facts Barns and Morgans⁴ have suggested that increased production of the diabetogenic growth-promoting complex of the anterior lobe of the pituitary might be the factor which is responsible for the increased size of the foetus and for the late foetal catastrophes, as well as for the development of the diabetes. They further suggest that the effectiveness of oestrogens, if they produce the results claimed by White, lies in their ability to inhibit the anterior pituitary. Some experimental work lends support to the first part of this hypothesis, for the administration to pregnant rats of an extract of ox anterior pituitary lobe containing the diabetogenic growth-promoting complex has been found to produce up to 100% of stillbirths, depending upon the dosage.¹⁰

Whether or not either of these theories is correct, it would seem that an investigation is urgently required to compare the effects on foetal mortality of (1) no specific treatment directed towards saving the foetus, (2) termination of the pregnancy (usually by caesarean section) at the 36th week to avoid the late foetal deaths, (3) oestrogen treatment combined with termination, and (4) oestrogen treatment alone. It seems probable that termination of pregnancy has failed to reduce the overall foetal mortality because, while many late intrauterine deaths are avoided, it has increased the neonatal death rate due to prematurity (in spite of the large size of the infants). To be of real value, oestrogens—or any other therapeutic agents—must be able to avert late intrauterine death and so enable full-term birth to occur, with its much reduced likelihood of neonatal death.

NEW YEAR HONOURS

The medical profession will warmly applaud the great honour bestowed on Sir John Boyd Orr, F.R.S., one of the newly created barons. As director of the Rowett Research Institute, Aberdeen, he had a world-wide reputation in nutritional science, and between the wars did much to shake the complacency of those who believed that the people of Britain were well fed. Feeling, no doubt, the need for a bigger platform to urge forward his views, inspired by a determined idealism, he entered Parliament as an Independent after a by-election for the Scottish Universities in

1945. "I stand," he said then, "for a world food policy of production for consumption and distribution according to needs, just on the lines of the Hot Springs recommendation." Busy as he was, he at the same time acted energetically as the chairman of the B.M.A. Committee which drew up *A Charter for Health*, published in 1946. Sir John was re-elected to Parliament in the general election in 1945. Within a few months he was appointed Director-General of the United Nations Food and Agriculture Organization, and shortly after this resigned his seat in Parliament. His fearless and consistent advocacy of his views as Director-General of F.A.O. earned him world-wide admiration. It is good to know that the country will have the benefit of his wisdom in the debates of the House of Lords.

Three medical men have been designated Knights Bachelor. Professor Henry Cohen is Professor of Medicine in the University of Liverpool and vice-chairman of the Central Health Services Council. He rendered outstanding service to the B.M.A. as chairman of the Medical Education Committee, whose report was published last year. Professor Sydney Smith is Regius Professor of Forensic Medicine and Dean of the Faculty of Medicine in the University of Edinburgh, and his name is familiar as the author of a famous textbook. Mr. H. E. Griffiths is surgeon to the Albert Dock Hospital, London, and has done pioneer work in the rehabilitation of disabled persons.

Sir William Gilliatt has been raised from C.V.O. to K.C.V.O. Sir Wilson Jameson has been created G.B.E. Dr. Edith Summerskill, M.P., is to become a Privy Councillor. Many other honours have been deservedly bestowed on medical men and women, a full list appearing elsewhere in this issue.

"ANTRYCIDE"

"Antrycide" is a new synthetic preparation which appears to mark an important advance in veterinary medicine. The Under-Secretary of State for the Colonies, Mr. D. R. Rees-Williams, and the heads of the Pharmaceutical and Agricultural Divisions of Imperial Chemical Industries at a meeting at the Colonial Office on Dec. 29 gave some details about the use of this drug in the prevention and treatment of trypanosomiasis in cattle in tropical Africa. It was stated that trials in East Africa had demonstrated that a single treatment will cure cattle infected with *T. congolense* and *T. vivax*, and that it has been used with success against *T. brucei* infection in cattle, horses, and dogs, *T. evansi* in camels, and *T. simiae* in pigs. Experiments are still proceeding, but it is apparently possible to protect cattle against *T. congolense* for from four to six months in the majority of cases, and against *T. vivax* for a rather shorter period. Certain cases in which the disease has "broken through" after a shorter period are being investigated. *T. congolense* is the most harmful trypanosome affecting domestic animals in most parts of East Africa. Among cattle in British West Africa *T. vivax* is more important than *T. congolense*. It was further claimed that "antrycide" has no toxic effects, and that its administration by hypodermic injection is so simple that the presence of a veterinary surgeon is not necessary. At the same time, Mr. Rees-Williams said that there would probably be a greatly increased demand for veterinary surgeons in these parts of Africa because of the stimulus which would be given to cattle-rearing following the diminution of the ravages of the tsetse fly.

The supplies of the new drug, which it is hoped will amount to two or three tons this year, sufficient to protect 2,000,000 animals, will be limited at first to Government veterinary departments, those in Kenya, Uganda, and the Sudan having priority, following which field trials will be undertaken in West Africa. The research which led to the

discovery of "antrycide" has occupied four years. It has been undertaken by a team of I.C.I. chemists and biologists working first in experimental laboratories in Manchester and later in parts of Africa where trypanosomiasis is endemic, the work being based on laboratories in Khartum, Nairobi, and Entebbe, Uganda. The team was headed by Dr. F. H. S. Curd, Ph.D., who tragically was killed in a railway accident over a month ago. He, with Dr. D. Garnet Davey, Ph.D., another member of the team, jointly discovered "paludrine," the antimalarial drug, for which they were awarded the Society of Apothecaries' gold medal in 1947. A third member of the team was Dr. W. A. Sexton, Ph.D.; and the fourth, the only medical member, was Dr. Charles Melville Scott, who is at present in Africa and, before he became head of the biological department of I.C.I., was lecturer in materia medica at Edinburgh University.

The drug—a white crystalline powder soluble in water—is the result of that type of research in the new field of heterocyclic chemistry which has been described as "enlightened empiricism." A great number of compounds were tested, first of all in this country on trypanosome-infected mice, and later on cattle in Africa. After many failures a substance was discovered which had a slight effect on the disease, and then attention was directed to stepping up the potency. Ultimately the most effective preparation was found to be the one now presented, the serial number of which was M.7555. In reply to a question about how the drug worked, Dr. Cecil Cronshaw, group director in charge of the Pharmaceutical Division of I.C.I., simply said, "We do not know." The tests in Africa, which began a year ago, have been carried out in collaboration with the Tsetse Fly and Trypanosomiasis Committee of the Colonial Office, and further details from this committee and from the I.C.I. team will be awaited with interest.

RESISTANT STAPHYLOCOCCI

It is now common knowledge that strains of staphylococci resistant to penicillin are being encountered with increasing frequency, particularly in hospital practice, where cross infection accounts for their spread. Dr. Mary Barber, who reported a year ago in this *Journal*¹ that the proportion of such strains encountered among staphylococci isolated from actual lesions had risen in successive periods from 14.1 to 38%, now describes a more recent series of investigations in which the proportion of resistant strains isolated from a variety of sources in the same hospital has reached 59%.² It is noteworthy that two of these were cases of septicaemia: both patients died in spite of intensive penicillin treatment, and a positive blood culture was obtained from one of them when, owing in part to renal inadequacy, the blood penicillin content was no less than 8 units per ml. This paper also contains further interesting data bearing on the mode of origin of these strains and a discussion of the recently suggested idea that contact with other bacteria may restore their sensitiveness—unfortunately resistant strains were even commoner in mixed than in pure cultures, a finding which lends no support to this hypothesis.

Almost all staphylococci found to be naturally resistant to penicillin (as distinct from those artificially habituated to high concentrations *in vitro*) produce penicillinase, an enzyme which destroys the drug. The formation of this enzyme can be detected by the appearances in a primary culture in a "cup" or "ditch" plate. Barber mentions the observation made originally by Waterworth³ that

colonies of such an organism attain full or even abnormally large size at the boundary of the inhibition zone; having destroyed the penicillin in their neighbourhood they can grow unimpeded. The possibility of studying this and other phenomena connected with antibiotics by such exceedingly simple methods has perhaps discouraged more exact quantitative study. That a good deal can be gained by applying more exact methods is shown in the work of Gilson and Parker,⁴ who have defined a unit of penicillinase and devised a method for its accurate assay. They were thus able to determine the amount formed by 40 strains of staphylococcus. Twenty-two formed little or none, but the quantity formed by the remainder varied from 190 to 125,000 units per g. of culture. These findings gain their chief interest when compared with the results of a double test of sensitivity to penicillin, one employing an inoculum of only a few hundred cells and the other of 10,000 times that number. Except in the case of two strains a small inoculum of a penicillinase-forming organism was usually inhibited by quite a low concentration of penicillin, often not exceeding that required by a normally sensitive organism. On the other hand, a large inoculum of a penicillinase-forming organism grew in concentrations a thousand or more times greater, the degree of difference generally corresponding with the amount of enzyme formed by it. Thus, as these authors say, the "resistance" exhibited by the organisms is "an artefact introduced by the method of testing: it expresses simply the ability of the resting cell to dispose of the penicillin in its environment."

Gilson and Parker are not the first to point out that the size of the inoculum requires control in such a test, but their very thorough investigation emphasizes this necessity, indeed it seems to demand from the laboratory a much more searching investigation of the properties of a staphylococcus than has ever been contemplated hitherto if the probable effect of penicillin on it is to be predetermined. The results of treatment in, say, a case of septicaemia are likely to depend not only on whether penicillinase is formed but in what amount; and the possibility of clearing the blood stream, where there may be few bacteria, may be indicated by the results of a sensitivity test employing a small inoculum. That there is perhaps yet another factor, although it may only apply to comparison between different bacterial species, is suggested by the observations of Bondi and Dietz.⁵ They also studied the effect of inoculum size on the sensitivity to penicillin of Gram-positive penicillinase-forming bacteria and obtained similar results, but they found that the degree of variation did not depend on the total quantity of penicillinase formed but on the rapidity with which it was formed in the early stages of growth.

DEATH AT BIRTH

As the Registrar-General recently pointed out,¹ certification of the causes of death is at its least precise at the two ends of the age scale. Relatively few necropsies are performed after still-birth or neonatal death; yet the need for accurate information about the numerical importance of the various sources of danger to infant life is increasingly felt. The downward trend in infant mortality rates in recent years is the result of a decrease in the death rate in the later stages of the first year of life. The still-birth and neonatal death rates have, it is true, shared in the general improvement, but the rate of decline has been much slower among infants either at birth or in their first month of life.

In preventive action the concentration of effort should be during the dangerous first month. Effective action, however, depends on accurate information which, in this context, only post-mortem dissection can give. A recent report from the Bellevue Hospital, New York, is therefore to be welcomed, for in this Labate² summarizes the necropsy results in 78% of the 1,114 foetal and neonatal deaths occurring in the hospital during the ten years between 1933 and 1943. The four major causes of death were found to be prematurity, pulmonary lesions, birth trauma, and maceration (following antepartum or intrapartum death, often of unknown origin). Prematurity, the most important cause, accounted for 27.6% of the deaths among the cases examined—a finding consistent with previous studies of this type. Necropsy in such cases usually shows a generalized immaturity of the vital organs of the body. The maldevelopment of the lungs causes persistent cyanosis; renal function is inefficient because glomerular development has not been allowed to go on as usual to the thirty-sixth week; the alimentary tract is immature; and heat regulation is unstable. The four main objectives in the care of the premature child must therefore be the maintenance of body temperature, the prevention of cyanosis, proper nutrition, and the prevention of infection. The problem of prematurity must concern the obstetrician as much as the paediatrician; he must delay the onset of labour, be sparing in the use of sedatives, minimize the strain of the second stage by episiotomy and by low-forceps delivery, and be ready to apply vigorous measures of infant resuscitation after birth.

The plight of the premature child is often made worse by coexistent defect. Pulmonary lesions were a cause of death in 21% of viable premature babies on whom a necropsy was performed. Pneumonia was a particular hazard in the neonatal period, and 80% of the deaths due to this disease were the result of aspiration pneumonia. Among full-term infants, too, pulmonary lesions due to aspiration of amniotic fluid, pneumonia, haemorrhage, or cystic disease were the most frequent cause of death. Birth trauma, however, also accounted for many deaths in this group. Injuries were of three main types—intracranial, spinal, and intra-abdominal. Difficult operative delivery appeared to be the most frequent cause of injuries, the nature of which partly depended upon the maturity of the infant. Lacerations of the dura and subdural haemorrhage were the lesions most frequently found among full-term infants, while subarachnoid and subventricular haemorrhages were more common in premature infants. Spinal dislocations were apt to follow difficult breech delivery, and abdominal injuries such as rupture of liver were sometimes the result of too strenuous attempts at resuscitation in the premature.

Labate remarks that the value of surveys of post-mortem findings is to be judged by the lowered mortality rate which results from an application of the lessons learned. By that standard the fall in the death rates among infants delivered at the Bellevue Hospital in the ten-year period under review is an indication that these lessons have been successfully translated from the post-mortem table to the delivery room and the nursery.

WORLD PROGRAMME OF DISEASE PREVENTION

Every year the International Health Division of the Rockefeller Foundation publishes a report on its activities of special interest to health officers and other workers in the field of public health. The report for 1947 covers the world from China to Peru. In China the Division has started a programme of malaria control and research on typhoid fever; in Peru it is carrying out

special studies on the development of local health services. Two important subjects discussed are the continued prevalence of malaria in many parts of the world and progress in the control of yellow fever. Yellow fever is being studied under the auspices of the Division in East and West Africa and in many South American countries, and malaria in Italy and Sardinia, the Netherlands, the West Indies, and South America.

One rather ominous feature is remarked in connexion with the malaria control measures instituted in Italy. After a D.D.T. house-spraying campaign carried out in a coastal region north of Naples and in the Tiber delta it was found that, in contrast to previous experience, house flies were not affected. Apparently a race of flies abnormally resistant to D.D.T. has become predominant in these areas and also in other regions of the mainland where the insecticide has been in use for several years. Thus far all varieties of anopheline mosquitoes remain susceptible to D.D.T., and malaria transmission rates continue very low in controlled areas, but the general sanitary value of the spraying is lessened.

Another field of study is typhus fever. Experiments here have included the testing of para-aminobenzoic acid in the treatment of epidemic louse-borne infection, and the preparation has been found to have a distinctly favourable effect as regards duration of fever, incidence of complications, and mortality, though there are certain contraindications and the treatment is not always effective. Work is also being done on mice to find chemicals of value against the organism of scrub typhus.

On the general question of health care a representative of the International Health Division has undertaken a survey of international trends which took him to 12 countries. He noticed three major defects in the planning and legislation for medical services. The most serious was the complete failure, except in Australia, to consider the categories and numbers of personnel and their training required to establish the organization envisaged by the legislation. Another defect was that, except in South Africa, planning and legislation were for sickness rather than for health insurance. Finally, he found inadequate provision for the three chief lacks in medical care to-day—namely, chronic, mental, and rehabilitation services. Two other minor defects were disclosed: that in most countries planning had proceeded without reference to what was developing in other countries, and that the need for auxiliary medical personnel was almost completely disregarded. The United States, and to a lesser extent Canada, were the only countries in which the training of auxiliary personnel, apart from nursing, had been standardized with the level of training controlled by a national organization—but it is evident that the observer failed to notice what has been and is being done in Britain in this connexion. The same investigator calls attention to the backwardness of medical education so far as concerns the training of the general practitioner in preventive medicine, geriatrics, psychosomatic medicine, and rehabilitation: but it is added that because of its new Health Act Britain has a great opportunity of exploring and demonstrating the positive aspects of health.

The Rockefeller Fellowships are an important branch of the work of the Foundation. In 1947 the International Health Division directed the studies of 112 individuals to whom fellowships had been granted. Of these 112 the main interests of 65 were in public health administration. Nearly all of them were studying in educational institutions in the United States or Canada, but a few were engaged in field activities. The Fellows came from 26 countries, only one of them from England. The report is a great record of world endeavour complementing that of the World Health Organization.

THE PROBLEM OF AGEING

BASIC DIFFICULTIES OF RESEARCH

BY

V. KORENCHEVSKY, M.D.

(From the Oxford Gerontological Research Unit, Oxford)

Great interest in the problems of gerontology is being shown in medical and scientific circles and by the public at large. Misunderstandings on the subject among non-specialists, however, are sometimes considerable. Therefore a summary of some of the main difficulties of the problem and of gerontological research might be of interest to those who have no time to study the matter in detail.

Theories of Senescence

There are several theories of senescence. Professor Warthin (1929, p. 160) sums up his critical review in the following pertinent words: "In general they are all built upon insecure foundations, hypothetical substances and hypothetical changes that may be due to the processes [effects, V.K.] of senescence and not its cause. Not a single one of all these theories of senescence so far offered has a leg to stand upon; for the greater part they are pure hypotheses constructed about some single fact."

Professor Medawar (1946), in his conclusions, is equally emphatic: "The problems of old age and natural death are hardly yet acknowledged to be within the province of genuine scientific inquiry." He emphasizes that the gerontologist requires many accurate data, scientifically controlled, for his conclusions; he has no time for "anecdotes" and loose statements, such as those concerning very old age in some animals and human beings, various sweeping theories of senescence, etc. He rightly says that the present-day gerontologist is quite aware of the fact that he has to begin "the study of the problem of ageing from scratch," and that gerontologists "would first of all try to piece together a full empirical description of the phenomenon of ageing as it is reflected in structural changes of tissues and cells and, more particularly, in the type and intensity of tissue and cellular metabolism. Only scraps of such information are now available."

The theory recently suggested by Bab (1948) belongs to the same category as defined by Warthin: in this theory one of the two factors on which, according to him, ageing depends is the diencephalon, about which so far we know comparatively little, and the changes in which most probably are the effects of ageing and not one of its primary causes.

Thus it is clear that, until the main facts concerning this problem are discovered and pieced together by experimental and clinical research, gerontologists will not be able to construct any reliable theory of senescence.

Pathological Character of Present Ageing

The greatest difficulty, however, of gerontology is that we know practically nothing of normal physiological senescence and the normal span of life. Referring to man, Mueller-Deham and Rabson (1942) state that, "in the first place, the old patient is a sick one; and, secondly, the sick patient is an old one." The latter sentence would be more correct in a modified form: "and, secondly, the sick patient is ageing more rapidly."

It is obviously impossible to discover normal features and establish normal standards of physiological senescence unless normal individuals are available: they should possess the best hereditary characters, should live a normal span of life in normal conditions of nutrition and environment, and should be free from any disease that might leave after-effects on their tissues and organs.

It is clear that from this point of view those centenarians who are available at present are deficient in various respects for human gerontological research. To begin with, we do not know whether 109-112 years, the longest span of human life so far registered with reasonable accuracy (Korenchevsky, 1947), really is the longest one and cannot be extended further under

those more normal conditions of existence which will be discovered by science and medicine (Fisher, 1923; Dublin, 1942). The basic elements of normal life, such as proper hygiene and nutrition, are most probably still very far from ideal, in spite of the truly remarkable progress in these fields of physiology and medicine.

Moreover, senescence is complicated and accelerated by those pathological features and diseases which are not necessarily associated with normal old age, since they are not present even in some rare cases of less-pronounced pathological ageing (for example, senile mental deterioration, effects of improper nutrition, accumulation of and auto-intoxication with metabolic products, gastro-intestinal auto-intoxication, hypertension, arteriosclerosis, and certain disorders in the functioning of the heart, liver, kidneys, and glands of internal secretion). Hirsch (1945) shows this fact clearly for arteriosclerosis in one of his careful investigations dealing with the relation of this disease to the processes of ageing.

There are several promising lines of research concerning pathological senility, but only two examples will be mentioned.

1. *Auto-intoxication with Metabolic Waste Products.*—Some results of primary importance have been obtained with tissue cultures in the brilliant experiments of Carrel and his co-workers (1921, 1922, 1937), extended and supplemented by Cohn and Murray (1925), Hoffman *et al.* (1937), Goldschmidt *et al.* (1937), Medawar (1940), and others, and well summarized by Medawar (1946). In cells isolated from the organism and living *in vitro* as a tissue culture senescence and death could be greatly postponed ("indefinitely" as suggested by Carrel, 1937, p. 4) if the metabolic waste products were not allowed to accumulate. In such conditions the "old" cells (i.e., those from older animals) have just as high a capacity of growth as young ones. The old cells merely take a longer time than do the young ones in starting their growth. Professor Pearl (1922), similarly to Carrel, concludes that (p. 75) "senescence appears not to be a primary attribute to the physiological economy of cells as such," and (p. 67) "that the individual cells and tissues of the body, in and by themselves, are potentially immortal."

In connexion with these experiments *in vitro*, Carrel performed a striking although drastic experiment *in vivo*. The experiment has been described by one of his co-workers (Du Nouy, 1936). At the Rockefeller Institute there was a dog nearly 18 years old. The animal never stirred from its corner and could hardly get up to eat. It slept all day, its coat was coming out, its eyes were dim, and the eyelids were stuck together. Nearly two-thirds of its blood was removed, the red cells centrifuged, washed in Ringer solution, then mixed with fresh Ringer solution so as to re-establish the initial volume of the blood and reinjected into the dog. After recuperation the operation was repeated. After the second operation the dog not only lived but, when completely recovered, was quite different: it ran and barked, became lively and active—in particular, sexually active—its lids cleared, and its fur started to grow again. Although such a relief could be of a temporary character only, and the actual operation could not be considered for human geriatric research, the significance of the experiment is considerable.

2. *Nutritional Experiments.*—The experiments of Sherman and others (1937, 1939) and McCay (1942) and their co-workers suggest another promising line of gerontological research. They were able to obtain prolongation of the life-span and improvement of the health of rats either by adding an extra amount of vitamins and calcium to a diet already adequate in all respects (Sherman) or by quantitatively restricting such a diet (McCay). Carrel (1937) in experiments on mice obtained results similar to those of McCay.

Of course, the results of experiments on animals do not necessarily mean that the same effects will be obtained on human beings. Research on animals, however, must precede geriatric trials on human beings. Experiments on such short-lived animals as rats and mice give hope for a comparatively more rapid success in obtaining normal individuals with physiological senescence than do clinical trials on human beings. Moreover, attempts to change a pathological senility into a physiological one may perhaps bring about considerable changes in the human organism. This indicates the

possibility of grave danger, perhaps fatal, and necessitates therefore the greatest caution, and only by preliminary research on animals can we ensure absence of dangerous effects. It must also be emphasized that in research on gerontology the study of pathological senescence is as important as that of physiological ageing.

Definition of Old Age, and Tests for the Process of Ageing

At present, gerontologists must unavoidably be satisfied with a definition which disregards the most fundamental fact—namely, that we do not know the causes, features, and standards of normal physiological senescence. It can be expressed only in terms of the processes (effects) of ageing as we can observe them now. Because of this, until our knowledge of the subject is more complete such a definition can only be of a temporary character. Moreover, this definition should be based on facts which have been studied with reasonable accuracy.

From the point of view of these requirements the best definition of ageing has been given by Professor Warthin (1929, p. 74). He constructs it on pathological and clinical observations which have been obtained by all the investigators of the subject; namely, it is agreed that hypoplasia, or atrophy of organs, is one of the most important and typical changes and features of ageing. Hence Warthin defines ageing as a "major involution" of the living organism, of all its organs, tissues, and functions. Since all of them are correlated with and dependent on each other, the involution of each single organ, "once well initiated, may through the weakening or loss of the given function initiate or strengthen retrogressive changes in other organs. The various lines of involution are not wholly independent, but, in the general economy of the organism, aid and supplement one another until various vicious circles and correlations of retrogression are produced." Although this definition deals only with the simplest factual effects of ageing, it is very helpful in indicating various urgent schemes of gerontological research.

In the first place, a detailed investigation of hypoplastic and atrophic changes in the organs and tissues is very important, especially in the earliest latent form of relative hypoplasia as measured by changes in weight or linear measurements of organs and cells. The first results of such research were based on the data independently obtained in two American laboratories (Donaldson, 1924; Freudenberger and Billiter, 1935; Freudenberger and Clausen, 1937a, 1937b; Freudenberger and Hashimoto, 1937, 1939; Freudenberger and Howard, 1937) and in the Oxford Gerontological Research Unit (Korenchevsky, 1942, 1948; Korenchevsky and Jones, 1946, 1947, 1948). These data are in complete agreement and show that the relative decrease in weight of organs (relative involution) can be used as one of the tests for and indications of ageing in rats. Most probably this test will be reliable also for human material, as shown by investigations and recalculations (Korenchevsky, 1942) of the data so far available.

The test appears to be not only as good as many other tests of ageing but of great importance because it deals with one of the main changes and features both of ageing and of old age. It has to be supplemented, however, at least by histological examination.

At present, however, every test or indicator of ageing is handicapped by two difficulties. First, it is not known whether our tests will be valid for the processes of normal physiological senescence. Secondly, practically no feature of present-day senescence can be regarded as specific for old age only. Any of them might be present in or after some diseases, or occur in the changes produced by mental or physical stress and duress, or develop in or after some other pathological conditions. For example, in some rare cases the hair does not become grey in old age, whilst in some young ones it becomes grey in a very short time under the stress of an emotional crisis. In young rats certain vitamin deficiencies produce greying of fur (Unna *et al.*, 1941; Ansbacher, 1941; Ralli and Graef, 1943), atrophic skin (Morgan and Simms, 1939), and osteoporosis (Korenchevsky, 1922). Baldness might start to develop at an early age, or (Hamilton, 1942) can be produced by suitable doses of androgens.

A premature appearance of senile wrinkled skin was observed and described by Merschejewsky (1876), Pelikan (1876), Pittard

(1934), and Tandler and Grosz (1913) in castrated men. Arteriosclerosis, hypertension, senile kidneys, senile heart, etc., might be almost absent in some cases of senescence. For instance, Hirsch (1945) did not find any signs of arteriosclerosis in 9.5% of autopsies in 400 old men aged more than 65 and examined by him.

From all the above-mentioned facts it follows that in present-day gerontological research a correct understanding and an accurate definition of the processes of ageing, or of the anti-ageing properties of any factor examined, could be obtained only after performance of several morphological, physiological, and biochemical investigations, both experimental and clinical (Korenchevsky, 1948). Since such a manifold investigation is technically impossible for a single research worker, the conclusions which he makes have to be drawn with reservations as judged by the test (or tests) of ageing applied in the experiments performed.

Causes of Ageing

So far we do not know the *main primary causes* of ageing, nor are we able to begin investigation of them before cases of normal physiological senescence are available. Heredity, according to some research workers (e.g., Pearl, 1922, 1931; Pearl and de Witt Pearl, 1934), influences longevity. If this is so, future research might discover a hereditary factor which has a connexion with the primary causes of ageing. Dublin and Marks (1942), however, emphasize difficulties of such research in man: "There may be strong beneficial influences from survivorship of parents on longevity of offspring . . . and these influences may have nothing whatever to do with heredity."

Professor Child (1915), one of the first gerontologists to have a sharp insight into and clear understanding of the problems of ageing, concludes in these words in dealing with the importance of heredity for geriatric research (p. 310): "The advance of knowledge and of experimental technique may make it possible at some future time to bring about a greater degree of rejuvenescence and retardation of senescence in man and the higher animals than is now possible, but when we remember that the present condition of the protoplasmic substratum of these organisms is the result of millions of years of evolutionary equilibration we cannot but admit that this task may prove to be one of considerable difficulty."

In the case of the *secondary causes* of ageing the possibilities for gerontological research are more satisfactory. These causes should be defined as non-specific but capable only of hastening the process of ageing. A great number of the secondary causes might include any of those non-specific factors which increase "wear and tear" and involution, general or only of one or more organs or tissues. They *accelerate* the main process of ageing, chiefly by producing "secondary vicious circles of ageing" (Warthin).

Infectious diseases, intoxications, deficiencies of vitamins or hormones or any other vital factor, any pathological changes in any tissue, organ, or blood vessels, physical or mental traumas, etc., might belong to this category. For example, hypothyroidism might produce a number of features of senility, even (Hertoghe, 1899) in the form of mild deficiency. Castrated men often develop some senile changes prematurely (Merschejewsky, 1876; Korsakow, 1898; Pittard, 1934), although they might preserve their mental faculties. Thus Korsakow writes (p. 340): "The eunuchs are ageing early, at the age of 40 producing an impression of 60-year-old men." Professor Pittard (p. 327) records: "The men castrated after puberty appear to age very rapidly, as also their congeneric fellows do, who have been castrated early. They become prematurely wrinkled and acquire soon the appearance of old women." In a patient with diphtheria the toxin producing degenerative changes in the heart accelerates its ageing, but obviously this is not one of the primary causes of physiological senile changes in that organ.

It is obviously illogical, however, to expect (as some authors do) that a secondary cause can *produce the whole* complex of ageing in all organs, tissues, and their functions when this cause is able to accelerate sometimes only a single process of senescence in one organ or tissue. Moreover, the secondary causes of senescence, not being the primary causes of ageing, produce chiefly their own primary action according to their functional nature (for example, effects specific for each

hormone or vitamin, or their deficiency). This action, although accelerating senile change or changes in some organs, in one or two other organs simultaneously might produce an effect which is typical of the specific function only but not of senility (e.g., a delay in thymus involution and, in male rats, adrenal hypertrophy after castration). It is an urgent task to investigate all these secondary causes and their vicious circles in order to illuminate their possible role in the senility complex and to understand how to break these vicious circles for geriatric purposes. From this point of view investigation of endocrine organs is specially important.

In the Oxford Gerontological Research Unit (Korenchevsky and Jones, 1946, 1947, 1948) an approach to this problem gave some significant results. Changes in the relative weights, and histological examination, showed that in female rats ovariectomy accelerates, and the combination of sex and thyroid hormones reverse more or less completely, the relative involution in the organs investigated. It was, however, strongly emphasized that in these experiments, as in any other research on ageing, the gerontological interpretation of the results obtained is impossible without manifold morphological, physiological, and biochemical experiments (Korenchevsky, 1948). It is obvious that ovariectomy might belong only to the group of secondary causes of ageing and therefore alone could never produce the whole syndrome of ageing, nor, for the same reasons, could hormones reverse this syndrome.

Moreover, since the action of the secondary causes, in particular that of ovariectomy, is not specifically ageing, and since the hormones might belong to the secondary reverse factors only—i.e., non-specific ones—discrepancies between the changes produced by them and the ageing or anti-ageing effects respectively are always possible. For example, androgens increase the involution of adrenals, whilst exerting an anti-involutionary effect on other organs investigated; ovariectomy at the beginning delays the involution of the thymus, but accelerates that process in some other organs. The clear predominance and importance of the special effects decide the gerontological significance of the factor concerned.

Summary

Gerontological research is handicapped by the basic difficulties of the problem; the span of life and the process of ageing are abnormal, and therefore the normal standard features and the primary causes of physiological senescence and old age are unknown.

It is possible, however, to investigate the secondary causes of ageing and pathological senescence as observed at present. This research is as important to gerontology as is that on physiological old age.

A definition of the secondary causes of ageing is given and the value of the present-day tests for ageing is discussed.

MEDICAL NEW YEAR HONOURS

The names of the following members of the medical profession were included in a New Year Honours List published in the *London Gazette* on Jan. 1.

Baron

Sir JOHN BOYD ORR, D.S.O., M.C., M.D., D.Sc., LL.D., F.R.S. Lately Director-General of the Food and Agriculture Organization of the United Nations.

Privy Councillor

EDITH CLARA SUMMERSKILL, M.R.C.S., L.R.C.P., M.P. Member of Parliament for West Fulham since 1938. Parliamentary Secretary, Ministry of Food, since 1945.

G.B.E. (Civil Division)

Sir WILLIAM WILSON JAMESON, K.C.B., M.D., F.R.C.P. Honorary Physician to the King. Chief Medical Officer, Ministry of Health and Ministry of Education.

K.C.V.O.

Sir WILLIAM GILLIATT, C.V.O., M.D., M.S., F.R.C.P., F.R.C.S. President of the Royal College of Obstetricians and Gynaecologists

Knighthood

HENRY COHEN, M.D., F.R.C.P. Professor of Medicine in the University of Liverpool.

HUGH ERNEST GRIFFITHS, C.B.E., M.S., F.R.C.S. Surgeon, Albert Dock Hospital, London, E. For services in the industrial rehabilitation of disabled persons.

SYDNEY ALFRED SMITH, C.B.E., M.D., F.R.C.P.Ed. Regius Professor of Forensic Medicine and Dean of the Faculty of Medicine in the University of Edinburgh.

C.B. (Military Division)

FREDERICK HARRIS, C.B.E., M.C., M.B., B.Ch., late Royal Army Medical Corps. Honorary Surgeon to the King.

LIONEL FREDERICK STRUGNELL, M.B., B.S., F.R.C.P., D.T.M.&H. Consulting Physician to the Colonial Office.

MONTAGU TRAVERS MORGAN, M.C., M.D., D.P.H. Medical Officer of Health, Port of London. Medical Adviser, Ministry of Transport

C.M.G.

ARTHUR BARTON PILGRIM AMIES, D.D.Sc., F.R.A.C.S., F.A.C.D., D.L.O. Professor of Dental Science in the University of Melbourne.

THOMAS AITKEN AUSTIN, L.R.C.P.&S.I., D.P.H., D.T.M., D.T.H. Colonial Medical Service. Director of Medical Services, Uganda.

RICHARD BRUNEL HAWES, M.B., B.S., F.R.C.P., D.T.M.&H. Consulting Physician to the Colonial Office.

MONTAGU TRAVERS MORGAN, M.C., M.D., D.P.H. Medical Officer of Health, Port of London. Medical Adviser, Ministry of Transport

C.B.E. (Military Division)

ROBERT WALSH MUSSEN, M.D., M.R.C.P. Surgeon Captain, Royal Navy.

C.B.E. (Civil Division)

WILLIAM ARTHUR BULLOUGH, M.Sc., M.B., Ch.B., D.P.H. County Medical Officer for Essex.

JOHN BURTON CLELAND, M.D., Ch.M. Formerly Professor of Pathology in the University of Adelaide.

EMILY HANCOCK MCKINNON, M.B., B.Ch., of Dunedin, New Zealand. For services in the field of medicine and welfare of women.

NORMAN MANSON, M.B., Ch.B., D.O.M.S. Warden, Hospital of St. John, Jerusalem.

WILLIAM BENTLEY PURCHASE, M.C., M.B., D.P.H. H.M. Coroner for the Northern District of London.

WILLIAM ROBERTS, M.D., F.R.C.S. Medical Superintendent, Grace Hospital, Newfoundland.

O.B.E. (Military Division)

STEPHEN MACKENZIE, M.R.C.S., L.R.C.P., D.C.H. Lieutenant-Colonel (temporary) (now Major), Royal Army Medical Corps.

SIDNEY RICHARD CARLYLE NELSON, M.D., M.C.P.&S. Wing Commander, Royal Air Force.

O.B.E. (Civil Division)

- Mrs. MARGARET MARY BASHAM, M.B., Ch.B., D.P.H. County Director, Monmouthshire Branch, British Red Cross Society.
- GEORGE FREDERICK BAXTER, M.R.C.S., L.R.C.P. Senior Surgeon, Public Hospital, Kingston, Jamaica.
- ERIC HATTAWAY BRIDGMAN, M.B., B.Ch. Superintendent, Rotorua Hospital, New Zealand.
- JOHN CHARLES JOSEPH CALLANAN, M.D. Director of Medical Services, Swaziland.
- CHARLOTTE ANN DOUGLAS, M.D., F.R.C.O.G., D.P.H. Medical Officer, Department of Health for Scotland
- CYRIL FRANCIS FERNANDO, M.D., M.R.C.P. Medical Officer and Physician, General Hospital, Colombo, Ceylon.
- GEORGE GIGLIOLI, M.D., M.R.C.P., D.T.M.&H. Honorary Government-Malariaologist, British Guiana.
- RICHARD MURCHISON MORRIS, M.D., D.P.H., D.T.M.&H., Medical Director and Secretary for Health, Bulawayo, Southern Rhodesia.
- HAROLD BURNET PORTEOUS, M.B., Ch.B. Wing Commander (ret.), Royal Air Force. Medical Officer, Board of Customs and Excise.
- ERNEST ALBERT HAROLD RUSSELL, M.B., B.S. Honorary Consulting Obstetrician, Queen Victoria Maternity Hospital, State of South Australia.

Hon. O.B.E. (Civil Division)

- FRANCIS AKANU IBIAM, M.B., Ch.B. Medical practitioner on the staff of the Church of Scotland Mission, Nigeria.
- LOUBE MARY-MADELEINE LENGUAER, Medical Officer, Leprosy Control, Nigeria.

M.B.E. (Civil Division)

- Mrs. OLGA KONSTANTINOVNA ABBOTT. Physician, Ethiopian Vice-Ministry of Health, Addis Ababa.
- CHARLES EDWARD ETHERIDGE, M.B. Admiralty Surgeon and Agent, Whitstable, Kent.
- JOSEPH GALEA, M.D., D.P.H. Medical Officer of Health, Malta

Mr. GEORGE NORTH, M.C., LL.D., the Registrar-General, was appointed C.B., and Mr. G. R. EDWARDS, the secretary of the Royal Society of Medicine, an O.B.E.

THE KING'S HEALTH

The following bulletin was issued from Buckingham Palace on Jan. 3:

Since the bulletin of Dec. 13, 1948, the King has made uninterrupted progress. His general health is entirely satisfactory. On both right and left sides the arterial circulation in the legs and feet is improving slowly. It is not yet sufficient to allow more than strictly limited activity when his Majesty leaves London to continue his convalescence in the country.

MAURICE CASSIDY.	J. PATERSON ROSS
THOMAS DUNHILL.	MORTON SMART.
HORACE EVANS.	JOHN WEIR.
J. R. LEARMONTH.	

The bulletin is the fifth to be issued and the first which has been signed by Dr. Horace Evans, who has been physician to Queen Mary since 1946.

Nova et Vetera**ARE FEMALES BORN CO-TWIN WITH MALES STERILE?**

"It is a popular opinion, and I do not know any instance to discountenance it, that if twins be of different sexes, the female is sterile."

Your inquirer (*Journal*, Nov. 13, p. 887) may be interested in a work by Sir James Young Simpson* in which these words (taken from an obstetrical publication dated 1843) form the opening sentence. Famous as the first man to use anaesthesia in childbirth, Simpson has many other claims to undying fame; and during his short but intensely active life he poured forth a seemingly endless stream of writings covering an amazing variety of medical and scientific subjects. This article is typical of his style, and, although it is now a hundred years old, extracts from it may interest present-day readers.

Having, as was his wont, arrested his reader's attention by an apt quotation, Simpson plunges without ado into his discourse. First he deals with comparative physiology. From John Hunter (1779) he quotes:

**Selected Obstetrical and Gynaecological Works of Sir J. Y. Simpson*, ed. by J. Watt Black, p. 822. Edinburgh, 1871.

"When among black cattle, the cow brings forth a male and a female at the same birth, the male is a perfect bull-calf, but the apparent female is almost always imperfect in its sexual organization. Female cattle of this kind, born co-twin with males, have long been distinguished in this country under the name of freemartins. In external appearance and form of body they usually resemble the ox and spayed heifer more than either the entire male or the entire female of the species. They commonly grow to a larger size than either the bull or the cow, and have horns like those of an ox, and a tone of bellowing similar to his, with the same marked disposition to become fat under the use of nourishing food. In general they do not show any sexual desire for the bull, or the bull for them."

Hunter's dissections showed that the external sexual organs were of the female type but that the vaginal canal was contracted in its upper part, and the internal female organs, the uterus, Fallopian tubes, and ovaries, were "altogether rudimentary and imperfect in their structure." After reference to other authorities, Simpson records his own examination of freemartins "killed in the shambles of this city" and tells how he "found all of them formed after the imperfect and abnormal type pointed out by Mr. Hunter." He continues:

"The butchers in Edinburgh and its neighbourhood, of a number of whom I have made enquiries upon the subject, seem to be perfectly familiar with the fact, that in the free-martin, whose flesh they usually reckon of a superior quality, the womb, or calf-bed, as they term it, is in almost all cases apparently wanting; and all our intelligent agriculturists in the Lothians are acquainted with the sterile character of these animals."

Characteristically, Simpson now turns to the examination of old Roman writings. He finds reference to the existence of sterile cows ("*tauræ*"), which were set aside and trained to the plough; and he speculates on whether these animals were, in fact, freemartins.

Next he indicates the complexity of the subject. He recounts cases in which, despite the circumstances of its birth, the female calf of dissimilarly sexed twins had, when grown, full reproductive abilities. He states that he had been unable to find any evidence of the occurrence of a freemartin in sheep or other animals which are normally uniparous but occasionally produce opposite-sexed twins:

"I have hitherto been equally unsuccessful in tracing out any instance of a twin mare or she-ass, born under the circumstances already pointed out, being reared to maturity. The mare, indeed, appears only in extremely rare cases to produce twins, and these . . . seldom survive for any length of time after birth."

Turning now to the human species, he states:

"A prejudice in reference to the infecundity of human females born co-twin with males exists to a considerable extent amongst the peasantry of the Lothians, and has very probably been derived from the analogy of the free-martin cow."

He abruptly forces the importance of this matter on the reader's attention by the quotation:

"The mischief to which the opinion might give rise, in causing a girl to be rejected as a wife for a defect, or taken for an excellence, according to sterility might be regarded, which she did not possess, is incalculable."

He next presents records from Edinburgh, Dublin, and London hospitals to show the frequency of dissimilarly sexed twins and states that, contrary to current opinion, it was "by no means uncommon"; one case occurred in every 199 labours.

Simpson now turns to his main theme. He presents numerous records of cases in which the female of dissimilarly sexed human twins did in fact have issue. Included in these is a case of plural pregnancy, occurring in 1827, in which a female infant, co-quadruplet to three males, became herself in the course of time the mother of triplets. Of 123 females born co-twin with males he discovered that no fewer than 112 had families, and that only 11 were without issue although married for several years. He concludes that "females born under the circumstances we are considering were unproductive in the proportion of 1 in 10."

Before drawing conclusions from these figures Simpson wisely turns his attention to the proportion of unproductive marriages in the society in general—a subject on which there was at that time no available information. He had the records of two large self-contained villages examined—Grangemouth and Bathgate—"one community chiefly of a sea-faring population,

and the other of persons engaged in agriculture and manufacture." From these figures he concludes that, allowing for couples not yet married for five years, *one marriage in ten was without issue*. With admirable resource he "extended the basis of data" by examining the histories of marriages contained in a work on the "British Peerage" for 1833. In this case the proportion of barren marriages was, he found, 1 in 6½.

Simpson could now "form a just conclusion" that females born co-twin with males were at least as productive as females in general. He adds that error, if any was present, was in the direction of over-estimating the number of barren marriages in these females:

"In relation to such a question as the present, all minds are too liable to be impressed with and recollect instances illustrative of the supposed rule and common opinion, whilst the apparent exceptions to it are unattended to or forgotten."

Further, Simpson found that the fruitfulness of these women was not impaired. The average number of children born to each mother was 4½; while in the control group (this modern technical term is not used by Simpson!) the corresponding number was 4¾.

"The whole enquiry," he observes, "forms an apt illustration of an old remark, that in Medicine it often requires a much greater extent of observation and research to disprove satisfactorily an alleged and accredited fact, than was ever expended, either upon the original development or subsequent confirmation of it. In the present instance, the results have turned out to be perfectly contradictory to the opinion which I, in common with others, held regarding the infecundity of the female in double-sexed twins, when I commenced looking into the subject; and instead of finding my preconceived ideas confirmed by the investigation, they have, on the other hand, been completely confuted by it."

Finally, Simpson expresses great surprise at the phenomenon of the freemartin:

"For certainly it cannot but be considered as an extraordinary circumstance, that, in the cow, the twin existence in utero of a male along with a female should, as a general principle, lead to so great a degree of malformation . . . in the sexual organs, and in the sexual organs only . . . and be limited entirely to the reproductive organs of the female twin, while those of the male twin are perfectly and fully developed. . . . The whole series of circumstances, when considered in conjunction with each other, seems to form, in relation to the origin of malformations, one of the strangest and most inexplicable facts to be met with in the study of abnormal development."

Can we wonder at Simpson's amazement? No explanation, no glimmer of understanding, was possible. Knowledge of "chemical messengers" in the blood stream was more than half a century ahead.

As an example of a perfectly constructed paper, written in clear and arresting English, this publication of Simpson's must be hard to match. And how strange it is that the false belief he so clearly exposed and so forcefully dispelled should to this day linger on in some parts of our country!

J. CHASSAR MOIR.

Reports of Societies

CHELSEA CLINICAL SOCIETY

The third dinner meeting of the session was held on Dec. 14 at the South Kensington Hotel, S.W.7, with the president, Mr. Nils Eckhoff, in the chair. A most interesting discussion on "Films and their Influence" was opened by Mr. Sidney Gilliatt, of the J. Arthur Rank Organization, and Mr. Noël Langley. A sound film showing cinematic technique from its inception was also exhibited. The discussion was continued by Drs. Stewart Webb, Seth Smith, Keane, Eckenstein, Chadwick, McCormick, Guy Daynes, Skene Keith, Guy Beauchamp, Mr. Havelock Allen, Mr. Cutler, and Judge Norman Daynes. Mr. Gilliatt and Mr. Langley replied.

The Ministry of Transport has issued Amendment No. 3 to *The Ship Captain's Medical Guide, 1946*. It advocates "paludrine" as the best prophylactic against malaria, and states that this drug will in future replace mepracine in the Ship's Medical Stores. Copies of the Amendment are obtainable from H.M. Stationery Office or through any bookseller for 3d.

Correspondence

Malaya Branch of B.M.A. and R.M.B.F.

SIR,—You recently published (Nov. 13, 1948, p. 875) a letter from me expressing the thanks of the Royal Medical Benevolent Fund for gift parcels for the beneficiaries of the Fund sent by members of the B.M.A. in New South Wales. It is now my pleasant duty to inform your readers that gift parcels have also been sent by your members in Malaya. The recipients have been deeply touched by the kind thought of these colleagues far away when the donors themselves can hardly be living in a bed of roses at the present time. I send a message of heartfelt thanks to you, Sir, in the hope that it will thus reach all those who have shown such kindness and generosity.—I am, etc.,

WEBB-JOHNSON,
President,
Royal Medical Benevolent Fund.

Whither Tuberculosis?

SIR,—I was most interested to read Dr. G. Lissant Cox's letter (Dec. 25, 1948, p. 1118), as I myself have been concerned about certain trends discernible in the plans which are being outlined for the new regional chest services. It seems to me that some serious mistakes are about to be made. Dr. Cox suggests that if the chest physician or tuberculosis officer becomes too "clinical" he is in danger of losing his soul, and, although this is probably an overstatement, yet Dr. Cox is right in essentials and as usual has put his finger on the most important point at issue.

In the past I have always advocated that as far as possible chest clinics should be sited in the out-patient departments of general hospitals not only in order to rescue the T.O. from his isolation and to subject him to stimulation by the contact with and criticism of his fellow physicians, but also so that these physicians should come to understand something of the work that goes on in a chest clinic and see perhaps for the first time what real environmental medicine is. For it is in the environmental field that the old tuberculosis service did such great pioneer work. I had not foreseen, however, that with the acceptance of this principle the chest physician would be tempted to devote himself exclusively to clinical work and to desert the task which previously he had on the whole done very well. Yet this is precisely what is going to happen unless a stand is made. Chest physicians are demanding beds in sanatoria where they can treat their patients and "see them right through," as they say, and sanatorium physicians are asking for a share of the clinic work. Such a policy has a superficial attraction but it ignores the realities of the problem.

The treatment of phthisis from activity to quiescence is a very complicated business, requiring experience, patience, and skill. A pneumothorax is easy to induce, but its complications are numerous and, in unaccustomed hands, frequent. Many a patient would have lived a great deal longer if it were as difficult to do a pneumothorax as to do a thoracoplasty. Furthermore, therapy is becoming even more complicated by the introduction of specific drugs. I feel, therefore, that sanatorium physicians have a task before them which should exercise all their skill. The chest physician's job on the other hand is quite different, requiring a different sort of person. He has on the clinical side a wide field of differential diagnosis (for tuberculosis can simulate most other diseases) and minor therapy. His clinical ability must be no less than that of the sanatorium physician, for the assessment of the present condition and probable trend of an individual case requires skill and understanding which can only be acquired by experience in all branches of tuberculosis work. The exercise of clinical judgment only in diagnosis and assessment should not deter the man of the right temperament from this job, for it has compensations in the sphere of human relations. He has to do with management, aftercare, rehabilitation, and above all prevention. This latter covers such matters as sociology, psychology, and non-party politics, and will soon include the use of B.C.G.

It is on the field of prevention that the battle against tuberculosis will be won, as with so many diseases in the past, while

in the sanatorium-beds the individual casualties will be treated. Thus the chest physician's job can be one of the most satisfying in medicine. He should regard it as a reproach to his work if a patient is found in his area with bilateral phthisis. He should be ashamed of it and inquire closely how it came about. All his new cases should be minimal. It may even be that with improvements in bacteriological technique a new horizon of diagnosis is in sight, that in the future our patients will be x-ray negative and T.B.-positive, and that with proper management and advice we shall be able to prevent the onset of radiological phthisis. This may seem at present an impossible vision, but no one can deny that the outlook in the tuberculosis world has become immeasurably wider and clearer in the last ten years. With these considerations in mind and many others too numerous for a short letter, the task of the chest physician should be seen as one which gives both intellectual and emotional satisfaction. It would indeed be an exceptional man who could do it well and at the same time conduct good clinical therapy.—I am, etc.,

Rheumatoid Arthritis and Ruptured Tendons

SIR,—I have read with interest the paper by Dr. G. D. Kersley (Nov. 27, 1948, p. 942) and Dr. Peter London's letter (Dec. 11, 1948, p. 1039) on ruptured tendons in patients with rheumatoid arthritis. Early this term my attention was drawn to the condition found in certain shoulder-joints in the dissecting room. Out of 22 joints examined 10 showed some sign of arthritic change, and in 6 there were gross changes. In these 6 specimens the long head of the biceps tendon was fixed to the bicipital groove in the region of the surgical neck of the humerus. Judging by the atrophic belly of the muscle, I would say that the tendon had ruptured and become secondarily attached to the humerus. It would seem that the condition is much more common than has been previously reported, and I am arranging for a search to be made regularly in dissecting-room material.—I am, etc.,

J. T. AITKEN.

Fibrositis

SIR,—In the letter by Dr. T. Blanchard Sellors (Dec. 18, 1948, p. 1082) I would humbly submit it is indeed a remarkable pathology that accounts for his interpretation of the word "fibrositis." I am not aware that there is as yet an agreed definition of this vexed word, and I think it is because there are so many individual interpretations of it that there is so much misunderstanding. This is clearly illustrated in the many letters appearing in the *Journal* since Dr. James Cyriax put forward his controversial yet masterly attempt (July 31, 1948, p. 251) to clarify the issue. It is to be hoped that doctors will soon agree on some definite terminology.

That the symptoms of fibrositis coming on for no apparent reason are all in fact "the result of articular lesions" is well illustrated by the following chance occurrence. A man aged 56 complained of a painful and stiff neck. It had come on gradually during the last week, but when seen his head was flexed and he was unable to look up above the horizontal. On questioning, he said he had had pain and stiffness of his neck in 1943 and 1946. In 1946 he visited an osteopath, who "stretched" his neck so severely that he was much worse.

The examination was instructive. The head was held stiff and was moved most cautiously. All movements were limited, but especially side flexion both to the left and right and rotation of the chin to the left. Passive movements were only slightly increased, being limited by pain. Resisted movements caused notably no pain. On palpation there was marked tenderness on the right postero-lateral aspect of the neck, mostly localized opposite C2–C3, slight tenderness between spinous processes C2–C4, and much tenderness at the occipital insertion of the right trapezius and semispinalis capitis muscles. The left trapezius (upper outer border) was very tender. Shoulder and elbow-joint movements were free.

A course of radiant heat and massage was arranged the same day, as he had found it of benefit before. However, the following day he phoned the masseuse asking her not to come, as when he woke up that morning he found he could look around naturally, move his head freely in all directions, and was quite free from pain. On examination later this was confirmed. A truly remarkable "fibrositis."

The diagnosis was that of derangement of a cervical intervertebral joint, C5–C6 or C6–C7, osteoarthritis with loose-body formation in a man of this age being very common. Reduction or replacement of the loose body had occurred naturally. Confirmation of this diagnosis was presented in a letter from the patient's previous doctor, who reported as follows: 1942, lumbago and sciatica; 1942, severe fibrositis of neck; 1943, coccygodynia; 1943, neuritis of left arm, secondary to stiff neck; 1946, right suprascapular fibrositis; 1946, some anaesthesia of left forearm.

It is interesting to note the combined cervical and lumbar disk lesion, which is so frequent an occurrence, and to observe the value of manipulation in such lesions.—I am, etc.,

Ryde, Isle of Wight.

"Comedomastitis"

SIR,—For some time I have been puzzled by two cases of "chronic mastitis" which did not fit into the usual description of this disease.

The first case I saw at the Metropolitan Hospital three years ago, when a married woman of 50 presented herself with what appeared clinically to be a scirrhus carcinoma of the breast. It was not until after radical mastectomy that the tumour was sectioned and the breast revealed caseous debris in the large ducts and a cyst which was filled with similar grumous material. The pathologist reported that there was no evidence of malignancy in the portion of the breast and that the condition was one of chronic cystic mastitis; he remarked that the ducts and cysts were filled with milk-like debris.

The second case occurred in private practice last year, and was in a single woman of 38 who had multiple smooth swellings in both breasts. Clinically there was no evidence of malignancy, and chronic cystic mastitis was diagnosed. A biopsy was performed in order to reassure the patient that the condition was not malignant, and it was found that a thick grey material could be squeezed from the large ducts like toothpaste out of a tube. The pathologist reported that microscopic section showed chronic cystic mastitis, but he noted that several of the larger cysts were filled with milk-like debris resembling a galactocoele.

I could find no reference in the literature to a description of this condition. Sampson Handley mentioned duct catarrh, where plugs of epithelial debris blocked up the ducts, and Cheatle had noted dilated ducts with retained secretion in carcinomatous breasts. Tice, Dockerty, and Harrington have recently given a full account of this condition under the name of "comedomastitis." They state that:

"Comedomastitis is a disease of the breast characterized by dilatation of the lactiferous ducts, which are distended with inspissated grumous material that may be expressed from the cut ends of the ducts much as comedones are expressed from ordinary blackheads. It is a disease of the large ducts, in contrast to chronic cystic mastitis, which is a disease of the acini and ductules. Marked clinical similarity to mammary malignancy may be present when comedomastitis results in an indurated area of the breast which is fixed to the skin and is associated with a retracted nipple."

There is little doubt that this condition is a definite pathological entity, although it is intimately related to chronic cystic mastitis; as Tice, Dockerty, and Harrington point out, time may prove that the two types are responses to different hormones and that comedomastitis is merely a phase in the constantly changing panorama of breast pathology.—I am, etc.,

Treatment of Infertile Marriage

SIR,—I disagree with the criticisms of Miss M. Moore White and Dr. E. Friedmann (Dec. 11, 1948, p. 1035) of Mr. Christie Brown's paper. They surely seem to have missed the main object of his article. Most people who deal with infertile marriage will agree with Meaker's¹ view that sterility often results from multiple causative factors. He further points out that any one of these factors is often insufficient in itself to prevent conception, whereas all of them combined are able to

depress the fertility level below the threshold for conception. On the other hand, the removal of one of these impediments will often result in a rise in the fertility level above the threshold for conception. This of course is the explanation why different procedures in the past have all had their zealous advocates.

Furthermore, many women seek advice on account of sterility but are unwilling to submit to special investigations. Mr. Christie Brown describes a simple plan which would appear to help a reasonable percentage, and it certainly warrants further trial in suitable cases. Miss Moore White and Dr. Friedmann also appeared to have overlooked that this simple plan was only advocated in cases where there was no clinical evidence of abnormality.

Mr. Christie Brown performs another useful service in stressing that the foetal environment is partly genetically controlled. In other words, the maternal capacity to retain the foetus depends on an adequate supply of hormones, which in turn depends on a healthy, well-developed chorion. The other factor, of course, is the capacity of the uterus to respond. Evidence and proof of the latter condition have now been produced, and a similar condition has been described in certain types of "anovulatory" menstruation. Proof of ovulation has been seen at laparotomy and normal hormone secretion shown by urinary assay, and yet the endometrium has not shown the usual response.

Without question, all the basic requisites for conception, production of ova and sperms, existence of an uninterrupted pathway, and a satisfactory nidation surface should ultimately be investigated, but surely there is no harm in trying this simple plan for some two or three months. Our object should be to achieve conception, and this does not necessarily include the cure of all the factors that are responsible for the infertility. —I am, etc.,

Breast-feeding

SIR.—Dr. H. R. E. Wallis (Dec. 25, 1948, p. 1121) courteously supplies me with some American statistics in support of breast-feeding. What a pity it is that we should have to go to America for these as well as for our bread-and-butter. One sees clearly that more bottle-fed babies die in infancy from gastro-enteritis and pyloric stenosis, but surely this is inevitable, as most of them have had digestive troubles since birth. At least in most practices a baby is left at the breast till something goes wrong, and the weaklings go to the wall or rather to the bottle.

Your correspondent is not impressed by my four healthy bottle-fed children and the conviction, born of twenty-five years' observation in general practice, that the mythical benefits of breast-feeding are one great big fairy story. Let me quote my late partner, Dr. C. B. Hutchinson, who has five healthy bottle-fed children and over fifty years of similar experience. He assures me that he has never been able to determine any extra incidence of disease or lack of immunity in bottle-fed children during adolescence or later life, and he warmly supports my view that much unhappiness and maternal misery could be saved by early recourse to weaning. If our ideas are sound, as I sincerely believe they are, it is only fair to our present-day mothers that we should be able to speak comfortable words to them when they relinquish the almost impossible task of synthesizing wholesome milk from snot, scraps, and sausage meat.

Nearly fifty years ago, when I survived bottle-feeding in the bad old days when only two or three indifferent baby foods were available, there was a very strong case for breast-feeding. In spite of this I have been blessed with personal health and vitality above the average. Now that such excellent baby foods are available at nominal prices I feel that the case for forced breast-feeding has collapsed and that we should, in fairness to our overworked young mothers, relieve them of this extra physical drain on the slightest pretext instead of starving their babies to breaking point. And I should like to be able to assure them with authority that they are in no way jeopardizing their baby's right to health and happiness in the future.—I am, etc.,

Perichondrium in Vascular Surgery

SIR,—As a plastic surgeon I have no experience of vascular surgery, but I have followed with interest all the great advances in the latter during the last few years. All plastic surgeons are interested in the reaction which occurs on the reception given to similar and dissimilar tissues when brought into contact with each other—this is the basis of successful grafting. In addition a few years ago I did some research work on the subject examining histologically the effects produced in rabbits' tissue by the introduction of a large number of substances. Perichondrium, when stripped from the costal cartilages, is tough and fairly strong, and has the property in an unusual degree of forming rapid adhesions to other tissues, promoting a local fibrosis and itself undergoing contraction. It would seem that these are properties which vascular surgeons are seeking in a ligature material.

If sufficient perichondrium can be obtained for the case would have the advantage of being living tissue, and would quickly form strong adhesions to the blood vessel concerned and to surrounding tissues; it would not be absorbed like catgut, nor produce necrosis like silk (if tied tightly), and moreover, would tend to get tighter as it contracted. The contraction starts as soon as the perichondrium is free; therefore it should be removed only immediately before it is wanted. With the use of vitallium or acrylic tubes for uniting a divided artery it is admitted that the weak point is the ligature, and indeed it must be, for the free ends of the blood vessel beyond the silk ligatures must inevitably die if the ligature is tight enough, because of the destruction of the vasa vasorum. Whereas with fresh perichondrium new live cells grow on and would unite the blood vessel and the ligature very quickly, and moreover, instead of getting slack, it would get tighter.

I have used perichondrium chiefly for securing individual muscles of the face when they have by accident been avulsed from their attachments with the production of considerable disfigurement and disability—e.g., the orbicularis oculi. Strips of perichondrium used thus get a firm grip of the muscle and periosteum and promote adhesions most satisfactorily, and do not know of any other substance, vital or non-vital, which will accomplish this purpose more than temporarily. Fasci lata is quite useless for the purpose; it has no adhesive or gripping properties, and a knot tied with it rapidly comes undone unless very carefully sutured.

As for the reasons for this adhesive reaction, it may be that more histamine is released by damaged perichondrium cells than by cells of other tissues, and that this produces a strong local reaction on contiguous tissues; or the clue may lie in the following sentence taken from Wells's *Chemical Pathology* (1925, p. 470): "Chondroitin is a gummy substance, which in turn may be split into acetic acid and a strong reducing substance, chondrosin. Chondro-sulphuric acid is the characteristic component of cartilage, but is also found in the walls of the aorta and other elastic structures." These suggestions are offered in the hope that by the pooling of experience some benefit may accrue.—I am, etc.,

Wellington, New Zealand.

Millilitres Correct

SIR,—It is still the practice amongst manufacturers of medical requisites to state the dosage of their liquid preparations in cubic centimetres instead of the correct official millilitres. There may be laudable exceptions, but if so I have not come across them. One of the reasons which have been given to me for adherence to this incorrect nomenclature is that if millilitres were used many doctors would not understand them and uncertainty and confusion might result, especially when preparations were injected, since doctors generally use syringes marked in cubic centimetres.

I cannot believe that the millilitre is a strange and confusing measure to doctors; presumably they have used it from the beginning of their studies. Certainly all their measuring vessels are graduated in millilitres, and this unit, not the cubic centimetre, is official in the *British Pharmacopoeia*. Moreover, the enlightened policy of the *British Medical Journal* must by now have made the whole medical profession familiar with the millilitre. This being so, I do not think that a syringe marked in cubic centimetres would cause confusion, but nowadays such

PROGRESS in the relief of pain

Culmination of four years' work in the Glaxo Research Laboratories was the recent synthesis of an analgesic exhibiting unique properties. Originally coded 'C.B.11', the compound has been the subject of many clinical trials including that reported in the British Medical Journal (1948, 2, 553) 'Heptalgin'—the name now adopted—was shown in these tests to abolish pain and little or no cortical depression or drowsiness was observed.

'Heptalgin' has an analgesic potency about six times that of morphine, twenty times that of pethidine and at least three times that of 'amidone'; yet its acute toxicity is relatively much lower than that of these other compounds. Indeed, all available evidence points to a prominent place for 'Heptalgin' in the future of analgesia.

a wrongly marked syringe is a reproach to the manufacturer. The British Standards Institution has issued a specification for syringes in which graduation in millilitres is prescribed, and makers should follow this prescription. I understand that syringes correctly marked in millilitres are now obtainable.

It is conceivable that many doctors, far from being perturbed by millilitres, may regard the statement of doses in cubic centimetres as indicating that manufacturers are behind the times and as evidence of ignorance or carelessness which may extend beyond the use of an incorrect unit of measurement. It seems to me that the adoption of the millilitre would be a "selling point" for manufacturers—evidence that they are up to date and correct in this and presumably in other matters relating to their business.—I am, etc.,

J. M. HAMILL.

London, W.14

Mineral Oils in Bread

SIR.—In a letter published in this *Journal* (Aug. 21, 1948, p. 401) under the heading "Liquid Paraffin in Baking" it was shown that the use of even highly refined mineral oil in quantity as an ingredient in cakes involved a potential hazard to health. This conclusion was based on microscopical examination of cake batters which revealed that minute droplets of mineral oil of particle size less than 0.5μ persisted after baking. Evidence has been obtained by Frazer¹ that oil of such particle size can be directly absorbed through the intestinal wall and may lead to liver and other damage.

A detailed study of the potential distribution of mineral oils in bread has now been completed. Suggestions have been made to the baking industry regarding the use of such oils as tin-greasing agents and machinery lubricants, in which contact with dough may lead to some mineral oil absorption. It would appear that in view of the findings described later a clear distinction may be drawn between this form of use and incorporation of mineral oil in quantity as an ingredient in baked products.

The inherent dangers in the uncontrolled use of mineral oils have recently been reviewed²⁻⁵ and their use as ingredients in foodstuffs condemned. These views are based on such evidence as interference with the absorption of carotene, vitamin D, calcium, phosphorus, and vitamin K, and the ability of mineral oil to destroy cells in the lymph nodes and to induce (when impure) tumours in rodents. In certain cases necropsies on human subjects known to have used mineral oil over a long period have shown the presence of oily deposits in the lymph nodes. It must be emphasized, however, that there appears to be no substantiated evidence of refined mineral oils producing carcinogenic effects on ingestion, and the experimental evidence on the heated oils is still inconclusive. It might be thought that as dough is baked in an oven at 450°F . (232°C .) there is some possibility of the formation of harmful oxidation products. This, however, is unlikely to occur, since the internal dough temperature is less than 212°F . (100°C .), and even at the point of contact between the dough and baking-tin oxidation will be slight in the atmosphere of carbon dioxide, prevailing consequent on the fermentation conditions.

In view of the available medical evidence we have been guided in framing recommendations to the industry largely by the more clearly defined physiological defects which might accompany uncontrolled usage. These defects appear dependent on the oil being finely emulsified and absorbed through the intestinal wall. Alvarez⁶ has shown that even after ingestion in the liquid form emulsification may subsequently occur, being effected by the bile salts, oleic acid, and glyceryl monostearate present in the bowel and acting as emulsifiers.

Microscopical examination of bread doughs containing mineral oil stained with scarlet red has shown that the degree of dispersion depends on the efficiency of admixing the oil with the dough. Emulsification of the oil with the water present in the dough does not occur, and the oil either is distributed as a thin film inside the dough when mixing is slight or, when thoroughly mixed, it forms a film apparently surrounding each starch particle and/or penetrates the gluten in the form of an unbroken macro-film. These latter conditions do not occur to any appreciable extent in baking practice. When oil is used to prevent dough adhering to the baking tin it forms a thin layer over the dough and is slightly absorbed during the baking. Observation of oiled bread doughs—baked in a micro-oven by the technique described in the above-mentioned letter—has

shown no evidence of these films dispersing into droplet form. Thus it may be regarded that pure oil used as a grease or lubricant in bread production does not result in emulsion formation, and it is believed that subsequent emulsification in the bowel does not occur and that the chance of absorption through the intestinal wall is remote.

The difficulty of carbon tetrachloride extraction of the total mineral oil in breads and even pure starch "loaves" containing known quantities led us to the view that some of the oil was firmly bound to the crumb. A laboratory experiment was designed to copy somewhat the processes occurring when bread containing up to 2% mineral oil was ingested. Bread was boiled with 0.5N hydrochloric acid for a short time to imitate the breakdown caused by mastication, and the mixture was then rendered slightly acid and incubated at 38°C . for about 24 hours in the presence of the enzymes diastase and pancreatin to imitate the digestive process. It was found that the mineral oil still adhered to the residue resulting from this degradation and was little dispersed in the acid solution. This type of undigested residue might be compared with the roughage excreted from the human system. It is noteworthy that a parallel experiment in which glyceryl monostearate was added to the digest gave similar results.

It would appear, therefore, that mineral oils, when present in small amounts in bread, will not be liberated to any marked degree internally and that the possibility of emulsification and subsequent absorption is slight. Even this risk is eliminated should small residual quantities be metabolized, and evidence obtained with the paraffin deuteriohexadecane⁷ has indicated that such metabolism may well occur. The quantitative determination of mineral oil in bread will be described elsewhere. A survey of the quantity of mineral oil present in loaves purchased from 16 sources in Great Britain has indicated that the majority of bread examined falls within the recommendations suggested to the industry as a result of our investigations.

It has been suggested that bread should only contain mineral oil (1) if the quantity does not exceed 2,000 parts per million, and (2) if the chemical purity is not below that of liquid paraffin B.P. In these circumstances we believe that pure mineral oils may be safely used for the purposes specified in quantities not greatly exceeding 2,000 parts per million, as the chance of emulsification of oil in the bowel appears to be much smaller than with the same oil undiluted, and that at this level of usage the oil is probably largely excreted with the roughage, any residue being completely metabolized in the body.—We are, etc.,

Purpura Complicating Pregnancy

SIR.—I read with interest the article by Dr. J. A. Chalmers (Dec. 11, 1948, p. 1020) on purpura haemorrhagica as a complication of pregnancy but cannot agree with some of his conclusions. In a review¹ of the available literature on this subject in 1943, descriptions were traced of 68 cases of purpura during pregnancy, 75 cases having been stated to have been reported up to that time. It was shown that of the described cases only 5 could be classified as true thrombocytopenic purpura—the rest being purpuric manifestations of a variety of septic and toxic conditions. Some, indeed, were shown to be clinically cases of scurvy.

In the 5 true cases (which included one C. W. F. Burnett and I reported) all the mothers recovered completely. Hence true purpura complicating pregnancy does not appear to be a fatal condition. The fatalities occurred among the other cases, where the purpura was associated with such conditions as septicaemia and poisoning by various drugs. Furthermore, in the 5 true cases treatment varied in each case (in one case splenectomy was performed), but there were no fatalities, and spontaneous and complete recovery followed parturition in all cases. Treatment apparently has little influence upon the ultimate outcome. The amount of post-partum haemorrhage was in no case excessive, and it is obvious that efficient uterine contraction is still the factor of paramount importance in the prevention of haemorrhage.

In the case reported by Burnett and me the initial symptoms of severe epistaxis and widespread ecchymoses appeared at the

fourteenth week of pregnancy, and a platelet count at that time showed 15,000 platelets per c.mm., and at no time during the remainder of the pregnancy did the count rise above 163,000 per c.mm. At delivery the count was 76,000 per c.mm., and yet despite a perineal laceration there was no undue loss and the puerperium was uneventful. The infant's platelet count at the end of the first week was 332,000 per c.mm., and the mother's count gradually returned to normal over the ensuing 6 months. At no time did the patient have any specific treatment for her purpuric condition.

It appears, therefore, that (1) the figures quoted by Dr. Chalmers are not all cases of true purpura, and (2) there is nothing in the available literature to support the statement that the mortality rate is high or to provide any basis for dogmatic principles of treatment.—I am, etc.,

Manchester.

Retaining Patency of Veins

SIR,—The method described by Drs. A. J. Palmer and A. H. C. Walker (Dec. 4, 1948, p. 985) for ensuring patency of veins after cutting-down for transfusion, while no doubt effective, is too complicated to become generally adopted. It also suffers from the disadvantage that the wound is not closed while the cannula is *in situ*, hence presumably the reference to infection of the wound. The sutures described are designed to prevent leakage from the vein after removal of the cannula, but the same end can be achieved by direct pressure of a dressing.

A simple method of ensuring patency of veins after cutting-down is as follows: The vein is exposed in the usual way and the distal part tied off with silk worm gut or with some other non-absorbable suture material, the ends of which are left long. The cannula is inserted and tied in the vein the same way. The wound is then almost closed with one or two skin sutures, and the long ends of the ties on the vein are brought out of the wound alongside the cannula. In order to take out the cannula, the suture fixing it is pulled on until the knot appears and it is then cut out with fine scissors. The suture tying off the distal end of the vein is removed in the same way, and immediately a pressure dressing is applied. Surprisingly little bleeding occurs, and the wound in the vein seals off rapidly. Advantages claimed for this method are simplicity, closure of wound at time of insertion of cannula, and the avoidance of buried catgut.

I would emphasize that in routine ward work cutting-down should be the last resort, and where possible a needle or trocar and cannula should be used. These latter methods often fall into disrepute because of inadequate immobilization of the arm, causing displacement of the needle. This state of affairs is largely due to the fact that it is commonly believed it is possible to immobilize a limb with one back splint. Experience, however, shows that to ensure immobility of the limb at least three splints in the form of a box are necessary, or, alternatively, a light plaster cast should be used.—I am, etc.,

Calcified Cyst of Spleen

SIR,—Mr. J. H. Donovan's article (Dec. 25, 1948, p. 1106) records an interesting case of calcified cyst of spleen. He points out that his is the second case recorded in this country. This prompts me to mention that Mr. J. I. P. James and I published a case of calcified non-parasitic cyst of the spleen in 1943.¹ Cysts of the spleen present diagnostic difficulties, and in our case diagnosis was made before operation mainly on radiological evidence. The radiological features were: a round cyst in the left upper quadrant the size of a large orange, with a calcified rim, elevating the left diaphragm; the barium-filled stomach was pressed upon by the cyst and pushed to the right; the splenic flexure was displaced downwards. Intravenous pyelogram showed downward displacement of the left kidney. These radiological signs seem to be characteristic of splenic cysts, since they have also been described by other authors. Benton² suggests that the downward displacement of the splenic flexure is almost pathognomonic of large cyst of the spleen.

Calcified non-parasitic cysts of spleen are generally believed to be the result of trauma. Although no history of injury could be obtained in our case, signs of old haemorrhage were found in

the calcified cyst. In Dr. R. W. Bazeley's case,³ referred to by Mr. Donovan, a severe accident with fracture of the left lower ribs preceded the detection of multiple calcifications and of a large calcified cyst of spleen. On the evidence of the severe injury to the left lower chest and the presence of a large calcified cyst in the left upper quadrant with pressure signs on neighbouring organs similar to those seen on the radiograph in our case, I felt justified during the discussion on the case in suggesting a diagnosis of calcified cyst of spleen of traumatic origin.—I am, etc.,

London, W.1.

Dracontiasis

SIR,—I read with great interest Dr. W. L. M. Perry's report from Nigeria (Dec. 25, 1948, p. 1107) of his operation on a left inguinal hernia associated with a female specimen of *Dracontulus medinensis* in the hernial sac. In view of the comment that no previous record was available of the occurrence of guinea worm in this situation Dr. Perry and others amongst your readers in the Tropics might be interested in a similar case report which I submitted from Hyderabad (Deccan) and which was published in these columns (Sept. 16, 1933, p. 528).

The points of clinical interest in my own case (which was I felt, quite inadequately presented through a very scanty knowledge of helminthology and a complete lack of access to the literature of the subject in such localities) were these: an indirect right inguinal hernia containing small intestine and gangrenous omentum was strangulated with the guinea worm, a female 1 cm. long and alive, in close relation to the neck of the sac; hydrocele present on the same side was also dealt with. A welcome feature of the operation was the unaccustomed ease with which this long worm came out intact, without any need for having recourse to the usual dodges, such as injection of mercuric chloride solution, for facilitating its extraction. The patient's convalescence was uneventful.—I am, etc.,

W. E. THOMPSON.

Steroid Metabolism and Frontal Lobes

SIR,—Dr. F. Reitman (Dec. 18, 1948, p. 1064) publishes series of twelve 17-ketosteroid urinary estimations (based on the biochemical work from Charing Cross Hospital¹) before and three to four months after bilateral prefrontal leucotomy. It is interesting and instructive that the 17-ketosteroid results from this operation should conform on the whole to those obtained from unilateral adrenalectomy. In his series the average drop was from 13.4 mg. a day to 9.47 mg. a day, and Cases 9 and 10, with ketosteroids of 23.6 mg. and 20.3 mg. a day, look suspicious of cortical overactivity. Our last published analysis² of unilateral adrenalectomy showed a drop in the excretion of 17-ketosteroids in the cases in Group I (post-pubertal virilism) was as follows:

	Pre-operative	Post-operative
Average of 41 tests	17.6	8.5
Good results	17.5	6.8
Improved	19.1	9.9
Remained the same	15.1	8.4

As a general observation we regard a drop of 50% or over associated with the better results. The clinical results in this series were:

	Group II	Cushing's Type	Psychological Symptoms Present
Cases	88	14	15
Good	16	2	3
Improved	45	11	8
Remained the same	10	1	2
Deficient information	14	—	—
Died from other causes	3	—	—

Dr. Reitman does not go into any clinical details, but we have experienced psychosomatic-sexual changes of varying degree in a fair number of patients, and most of them have benefited by unilateral adrenalectomy.

An extreme case of this kind was described in 1939,¹ and the patient has remained perfectly well and was last seen a year or two ago. There is this curious twin control in the evolution of sex precocity and Cushing's syndrome, where the syndromes may respectively emanate from a hypothalamic tumour or basophil adenoma of the pituitary, or both from hyperplasia or tumour of the adrenal cortex, associated with increased output of androgens, which establishes the differential diagnosis. Now it would seem that the pituitary hypothalamic mechanism may be controlled by frontal impulses as far as the excretion of androgens is concerned, vicariously or direct from their production in the adrenal cortex—I am, etc.,

Toxicity of Soluble Phenytoin

SIR,—As I was going through the article by Dr T N Nauth-Misir (Oct 2, p 646) I was reminded of a similar case under my care.

A patient, 32 years old, had been an epileptic for the last 16 years and had potassium bromide, phenitoin, phenobarbitone, and phenytoin sodium in various doses at different times. In spite of that he used to get attacks quite frequently. He came under my observation from December, 1946. I started with $\frac{1}{2}$ gr (0.1 g) of phenobarbitone daily in three divided doses. Still his fits were not controlled, so I advised him to have one capsule (0.1 g) of phenytoin sodium and 1 gr (65 mg) of phenobarbitone. He had such a line of treatment for two and a half months. In spite of this he used to get fits once a month or so. I increased the dose of phenytoin sodium to two capsules a day, with 1 gr of phenobarbitone. Even after this there was no change in the frequency of attacks. He came to see me on Oct 7, 1947, complaining about his unsteady gait and headache. On questioning he told me that this had started on Oct 3, 1947 and now he was completely incapacitated. On examination I found that he had cerebellar ataxia, but I could not come to any conclusion about the causation of the condition. I examined him again and noticed that he had hypertrophy of gums. It was now quite clear he had been having phenytoin sodium two capsules (0.2 g) daily for seven months. The drug was stopped and he completely recovered in four days. No other measures were taken.

My case differs from Dr Nauth-Misir's case in that my patient had cerebellar ataxia after such small doses as 0.1 g daily for 24 months and 0.2 g daily for seven months, while his was a case of an acute severe toxic reaction (with cerebellar ataxia, etc) after a single heavy dose of 250 tablets of 0.1 g—I am, etc.,

S C KLSUNGAR

Temperature Recording

SIR—I have read the interesting article on temperature recording in children by Professor Alan Moncrieff and Dr B J Hussey (Dec 4, 1948, p 972) and the comments in the annotation (p 991) on this particular subject. It seems that despite the fact that temperature recordings have been common routine for centuries there are still differences of opinion on the various ways to record temperature and their significance.

In this connexion I would like to mention that temperature differences exist not only at various sites but even under the axilla if taken at the same time on both sides. I have been taking bilateral axillary temperatures in cases of pulmonary tuberculosis for some time and recorded differences. The differences seem to be connected with underlying disease in the chest, and they vary from fractions of a degree to 1° C. In cases of unilateral disease the temperature is higher on the side affected, and in bilateral disease on the side of greater activity. The differences are more manifest if recordings are made over a period of ten days—taking temperatures morning and evening on both sides for ten minutes with ordinary mercury thermometers.

Before inducing an artificial pneumothorax in cases of bilateral disease, besides other factors I find it useful to take bilateral temperatures, and I start an artificial pneumothorax on the side where greater activity is indicated by the average higher temperature—I am, etc.,

Harold Court Sanatorium Essex

M WEINBERGER.

POINTS FROM LETTERS

Diagnosis of Tuberculous Meningitis

Dr P E FITZPATRICK (Belfast) writes: I was extremely interested in Dr J T Lewis's letter (Dec 11, 1948, p 1076) on the early diagnosis of tuberculous meningitis by cerebrospinal fluid examination, especially in relation to the fall in the glucose content. What to my mind is equally important is the recognition of early clinical signs and symptoms, as this leads to earlier hospitalization and therefore earlier examination of the CSF and earlier treatment. I have in mind four cases of this disease which had, all of them, the same signs and symptoms. All four were boys of age group 5-10 years. In all a family history of pulmonary tuberculosis was present. In each case, about three months before the onset of the cerebral symptoms of headache, vomiting, photophobia, strabismus, etc., it was noticed that there developed on the hands, trunk, and knees particularly a crop of small papillomata, not unlike molluscum contagiosum, irregularly distributed. Associated with this were irritability and lassitude, with a disinclination to play games or to take an interest in toys. Inside three months all developed variable symptoms—mostly headache, intermittent temperature, occasional vomiting, and what to my mind was most significant of all, night terrors. Having the possibility of tuberculous meningitis in mind, I sent all four to hospital with a tentative diagnosis of tuberculous meningitis. In each case this was confirmed by the presence of tubercle bacilli in the CSF and a reduced glucose content. It would be interesting to know if this crop of small papillomata might be the skin manifestation of the mass dissemination of some abdominal, pulmonary, or other focus of tubercle bacilli, affecting at the same time the meninges and later producing all the signs and symptoms of tuberculous meningitis.

Herpes Zoster

Dr EDGAR PALMER (Lydd, Kent) writes: The treatment of this distressing complaint has been characterized by many different procedures and has been unsatisfactory in the past. As it is known that it is due to inflammation of the posterior nerve roots caused by a virus, and as it is also known that hexamine is excreted into the nerve sheaths, it seemed reasonable to prescribe this drug. Over a period of ten years in a rural practice, without the controls possible in a hospital I have found that tab hexamine gr 5 (0.32 g) t.d.s., p.c., has given most excellent results, causing the lesions to dry up quickly and the irritation and pain to subside rapidly. I have not had a case of post herpetic neuralgia since using this drug.

Temperature Recording

Dr S L FRANK (Preston) writes: From recent correspondence there seems to be some doubt as to how long a thermometer should be left in position. This must vary from case to case, as the rate of heat transference from the tissues to the thermometer bulb is variable and depends on such variable factors as the degree of dilatation of the blood vessels concerned. Thus in a suspected appendicitis, where the expected pyrexia is only slight and the peripheral vessels may be constricted from some degree of shock, it may be well over five minutes before equilibrium is reached between the oral temperature and the temperature of the mercury. It follows that the only correct way to take a temperature (irrespective of the site used) is to wait until the mercury stops rising—in practice, until two successive half minute readings are the same. In teaching this method I have found it necessary to ensure that the thermometer is not shaken down between each half minute reading.

Clouthing of Surgeons' Spectacles

Dr C G KAY SHARP (Leeds) writes: With reference to the letters on this subject from Mr G K Rose (Dec 4, 1948, p 998) and Mr R Wood Power (Dec 25, 1948, p 1123) may I draw attention to the fact that the problem of clouthing of spectacles has been solved by the provision of contact lenses? The lenses are kept free from clouthing by the movement of the eyelids. The average continuous wearing time is four hours—long enough for most surgical operations.

Procaine Penicillin

Dr L GREENFIELD (London, N5) writes: The introduction of procaine penicillin suspension has solved many of the difficulties of penicillin administration in general practice. The handling of the suspension, however, presents a difficulty which to some extent neutralizes the advantages. At present the substance is exhibited in rubber-capped bottles from which aspiration into the syringe even through a wide bore needle is not easy. There seems to be no reason why it should not be presented in 1 ml ampoules, from which the suspension could be aspirated into the syringe with the needle detached. The injection into the patient, using a needle of as small a bore as size 12, offers no difficulty and causes little discomfort.

Obituary

R. H. MILLER, M.D., F.R.C.P.

Dr. Reginald Henry Miller, who died in hospital in London on Dec. 23 at the age of 69, was consulting physician to St. Mary's Hospital, London, and the Paddington Green Children's Hospital.

The son of Dr. Andrew Miller, of Hampstead, he was educated at Charterhouse and at St. Mary's Hospital. He graduated M.B. in 1905 and proceeded M.D. in 1907. Dr. Miller was a general physician with a particular interest in paediatrics. He was medical registrar and pathologist at the Hospital for Sick Children, Great Ormond Street, in 1906-8, and he acted as secretary of the Section of Diseases of Children at the annual meeting of the B.M.A. in 1911. He was elected F.R.C.P. in 1917, and was an original member of the British Paediatric Association and an honorary member at the time of his death. He was the first editor, together with the late Dr. Hugh Thursfield, of the *Archives of Disease in Childhood*, and himself contributed a number of important articles to the literature on diseases of children.

Dr. Miller was a recognized expert on mental deficiency in children and a visitor for the County of Middlesex under the Mental Deficiency Acts. He also wrote extensively about rheumatic fever and heart disease in childhood. At Paddington Green he was responsible for starting the first supervisory clinic for rheumatic children in the London area. In 1939, soon after the outbreak of the recent war, he left London to become medical director of the Park Prewett General Hospital at Basingstoke.

Dr. T. Pearce Williams writes: The passing of Reginald Miller removes one more of that group of physicians who by their writings, based largely on clinical observation, did much to advance the art of paediatrics in the first thirty years of this century. I first met Reginald Miller in 1919 at St. Mary's, and later became a colleague of his at Paddington Green Children's Hospital. His fine figure, commanding presence, and resonant voice were combined with a ready wit and extensive knowledge of our language. His carefully chosen comments at committees were at times devastating, and he coined some most pertinent aphorisms. It was at Paddington Green that Miller carried out most of his work on the coeliac disorder, gastromegaly, and juvenile rheumatism. He discussed his problems freely with his colleagues, particularly with H. W. Perkins in the pathological department. Miller had a childish love of car riding, and for some years I called for him regularly to drive him to his rooms in Harley Street where, except for his hospital visits, he spent most of his days. I also lunched with him regularly and gained much from the breadth of his knowledge, his ready sympathy, and his interest in the development of paediatrics, particularly with the foundation of the British Paediatric Association. Miller's disposition was shy and sensitive, often masked by remarks apparently rude but rarely intended to be so. In 1911 he published a textbook, *The Medical Diseases of Children*, a copy of which I have before me. I doubt if any more recent publication has surpassed it in quality. He was much hurt by criticism which he felt was unfair and unjust, and could never be persuaded to revise the text for a further edition. A sincere Catholic, he yet had much of the Puritan in his nature and was almost ascetic in his habits. He worked quietly and unhurriedly, typing all his own letters, for neatness was a passion with him. His relaxation in the summer was a visit to Lords. He talked much of his family, in whose development he gained much happiness. His transfer to Basingstoke in 1939 broke the steady routine of his life, and he was little seen in London thereafter. Despite much importuning of his colleagues at Paddington Green, he never returned to take up work there, much to our regret. For much personal kindness I could never adequately repay him, and at the Children's Hospital we mourn the loss of a very dear friend and colleague.

Dr. Thomas Hunt writes: As a physician Reggie Miller possessed the great gift of recognizing serious illness almost instinctively, and, though there might be little to suggest it to others, he seemed at once to be able to pick out the important

from the trivial. He was essentially humble in his own estimation, and was never impatient in listening to the views of others, however junior. His patients were devoted to him, and his gentle kindness on his ward rounds was an inspiration to students. As a teacher he will be long remembered for his wit and paradox and his quickness at finding the *mot juste*. At times his lazy, almost slipshod manner and his large build—he was over 6 ft. 3 in.—seemed to give an impression of indifference; indeed, with minor ailments he could be frankly bored. But with an ill patient or an anxious relative he showed that understanding and sympathy which was part of his very gentle nature. As a man he hated violence and bustle, and both wars were a great ordeal to him. By temperament he was sensitive and cautious, with many of the attributes of the artist. His health was not good and for some years before his death he had had to take care of himself and avoid strain and over-exertion. Miller was at his best with children, and his work on coeliac disease, duodenal ileus, and especially rheumatic fever was outstanding. He had little sympathy with much modern psychiatric teaching and in particular disapproved of the Freudian school, but his views on the psychosomatic aspects of disease were in many ways remarkably ahead of his time. Miller was an expert prescriber, with a remarkable memory for mixtures and doses, and he used medicines with skill and a fine regard for their value as well as their dangers. Reggie Miller was one who, though he could be biting and even sarcastic if it was necessary, nevertheless delighted in saying nice things about others: in return he was almost childishly happy at knowing of his friends' affection and at feeling that he was welcomed and appreciated. His many friends will mourn the loss of a personality whose charm, wit, brilliant conversation, and gentle nature will not soon be found again.

WILLIAM SUSMAN, M.D.

Dr. William Susman, who died suddenly on Dec. 23 at the early age of 53, had been for many years lecturer in morbid anatomy and histology in the University of Manchester. He was a graduate in arts and medicine of Queen's University, Kingston, Ontario, and his interest in pathology was already obvious in his student days. After qualifying in 1923 he was awarded a Hoffmann fellowship and spent two years in Edinburgh, where he studied under Lorrain Smith and held a number of junior appointments in the pathological departments of the University, the Royal Infirmary, and the Royal Mental Hospital. In 1925 he went to Manchester as assistant lecturer in bacteriology in the department of pathology under Shaw Dunn. In recent years his main hospital appointments had been those of senior pathologist to the Manchester Royal Infirmary and honorary pathologist to the Manchester Royal Eye Hospital.

Dr. Susman was a keen research worker and published some twenty-five papers. Many of these reflect his special interest in diseases of the ductless glands and include a classical paper on atrophy of the adrenals as a cause of Addison's disease which was published in the *Journal of Pathology and Bacteriology* in 1932. His paper on intraocular tumours, which appeared six years later in the *British Journal of Ophthalmology*, has also been recognized as outstanding. In recent years administrative work, both within and outside the University, has claimed much of his time. He was an active member of the Board of the Faculty of Medicine and of its various committees. A member of the British Medical Association since 1924, he was a member of the Non-Professorial Group Committee from 1937 to 1946, of the Special Practice Committee in 1938-9, and of the Special Committee on Patents in 1944-5. Medical lecturers throughout the country have reason to remember him gratefully, for he was largely instrumental in founding the Association's Non-Professorial Group, which grew steadily in strength and influence under his chairmanship.

A vigorous and effective teacher of morbid anatomy and histology, Dr. Susman had a clear grasp of the needs of the medical student, and he never lost the zest and freshness that keep teacher and student in contact. Many generations of students will remember him with respect and affection. His great experience was always freely at the service of his colleagues and others, and his loss as a consultant will be widely felt.

From 1915 to 1919 Dr. Susman saw service in the Canadian Army Medical Corps, in the 8th and 2nd Duke of Wellington

egument, and in the Royal Flying Corps, and he was twice wounded, in the recent war he served as a medical officer in the Home Guard. He is survived by his wife and one son, a student of medicine, and to them all who knew him will desire to express their sympathy.

Dr JOHN MOFFAT LOGIE, of Burntisland died on Dec 20, and with his passing Fife has lost an outstanding personality in the medical profession. He was proud of the fact that he came of humble stock, and, in his own words *per vias luras* he qualified as a chemist and with his savings went on to graduate M.B., Ch.B. at Edinburgh University in 1910. For a time he was a house surgeon at the Royal Infirmary, Dundee, and then he settled first in Aberdour, later moving to the neighbouring busier town of Burntisland. From there Dr Logie conducted a large general practice and endeared himself to many patients. He was medical officer of health to the town of Burntisland—one of the few remaining medical officers of smaller burghs. He was the embodiment of all the good qualities which go to make a first class family doctor. So successful was his medical career in his own town that he received a public presentation on his recent retirement. Dr Logie read widely, and was a keen student of the classics all his life. He was an active member of the B.M.A. in Fife, and took a great interest in its work. His contributions to discussions were always marked by his complete honesty of purpose and opinion. He was a past president of the Fife Branch. A sincere churchman, he was closely identified with the affairs of St Serf's Burntisland where a memorial service for him was held on Dec 22 and attended by many of the local people. He is survived by his wife and daughter to whom we offer our sympathy.—J.M.

Dr ARTHUR ANDERSON, who was senior medical officer of the Glasgow Education Health Service, died on Dec 22 at his home in Victoria Park Gardens at the early age of 53. Dr Anderson was an M.A. of Glasgow University and graduated M.B., Ch.B. in 1922. He proceeded M.D. in 1924 and took the D.P.H. in 1943. He was appointed senior medical officer only in January, 1948, but more than twenty-four years of his professional career had been devoted to the Glasgow Education Health Service. During this time Dr Anderson made a special study of rheumatic disease in school children, and he was expert in eye conditions and refraction. One of his greatest interests was in the nutrition of the children and he was ever watchful that the school meals should provide a good balanced diet. At the time when he acted as school medical officer for the Partick area he knew practically every child and parent in his district. Dr Anderson was held in the highest esteem by his colleagues and was popular with teaching staff and pupils alike. On the appointment of the late Dr J. Miller Young as senior medical officer of the Education Health Service, Dr Anderson was appointed senior assistant medical officer. He was a good administrator and assisted materially in the building up of the department to meet the provisions of the recent Education Act. He was an elder of Partick Parish Church and an active member of the Partick Medical Association. He had few hobbies outside his work, to which he gave his whole attention. During the war-years Dr Anderson trained many hundreds of the citizens of Glasgow in the essentials of A.R.P. and first aid. He is survived by his wife and a daughter.

Dr GEORGE HENRY CHAVASSE MOLD died on Dec 24 at the age of 64. Dr Mold studied medicine at Birmingham University and graduated M.B., Ch.B. in 1908. After a brief period as a house physician at the General Hospital, Birmingham, he went into general practice. During the 1914-18 war he served as a captain in the R.A.M.C., and not long after demobilization he settled in Sussex.

G.S. writes: Dr Mold came to Cross-in-Hand, Sussex, over nineteen years ago and a few years later we became partners. One could not have had a more loyal partner, nor a more conscientious or harder worker. He never spared himself in spite of ill-health during his last few years here. He served on the National Insurance Committee for East Sussex and helped in Red Cross work. He found a home to retire to in Gloucestershire, where he was enjoying his garden and a well earned rest. His last illness came unexpectedly, and although he knew the end could not be long delayed he bore it very bravely and showed great courage. Even a week before he died he dictated part of a letter showing interest in old friends here.

Dr KASARGOD SOMNATH BHAT died recently at Karkala, South Kanara, Madras Province, India at the age of 63. Dr Bhat, who studied medicine at Madras and later at St Bartholomew's Hospital, qualified in 1915, and was in practice in SE London for many years. During the war he

acted as medical officer for a number of the Bermondsey shelters. He returned to his native province only in 1944.

Dr K. Mahli writes: Dr Bhat was my friend during the last twenty six years. He did for me and a number of others in the same circumstances a great service—namely, gave me a start. He not only bought instruments, including a dental chair, but sent us patients. He was always gruff, monosyllabic, and no too well dressed, but he worked hard and gave generously. His learning was very wide. He always knew the latest medical literature, the best articles on chess, and he was interested in botany. His type is rare. He never spoke of his good deeds, but I discovered many, always in roundabout ways—although I saw him for many years at least once a week. The world is the poorer for his loss and many of us are the sadder.

Dr Cranston Walker writes: To students Arthur Robinson (Dec 18, 1948 p. 1084) had many outstanding characteristics. The movements of his spare figure were quick, energetic, and accurate. His decisions also were quick, and his intentions proceeded immediately and smoothly into action. He never seemed to waste a moment. His speech though quiet was equally quick and efficient. His manner of entering the dissecting room was an economical rebuke considerably effective to anyone who lounged or slouched. He disallowed smoking there. His knowledge of human anatomy was amazing and his understanding profound. He knew the body with intimate familiarity not only as it is usually placed and described, but in any attitude and from any aspect or direction in broad view or in the minutest detail. He could answer any question, however recalcitrant, without an instant's hesitation and apparently with complete infallibility. Evidently he had prepared himself for his work of teaching anatomy with most exacting thoroughness and devotion. He probably had great powers of visualization, and in three dimensions, so that in his mind any structure under attention stood out solid in a translucent body and round it he could see vividly, as he liked, any other structures, and could remove them, replace them, or render them transparent at will in order to make plain any matter of structure or relation. His blackboard drawings were done with great rapidity. He appeared to be building up structures, or occasionally cutting down on them according to the solid images in his mind, not drawing after memorized diagrams. He often used the broad surface of the chalk to cover areas quickly, subordinating the use of outline. He carried on research with persistent vigour especially in embryology, but never allowed this to encroach on his teaching. His devotion to this, and to the needs of anatomy students at all stages was so eager and so successful that infection with his zeal was inescapable. It was perhaps most felt in his informal dissecting room tutorials. He had no need to assert authority; his manner was always that of a helpful energetic friend—who had given considerable attention to anatomy—leading suavely to knowledge and understanding.

Medico-Legal

VISCERAL TRANSPOSITION AS A DEFENCE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A young man on trial for murder in the Central Criminal Court in Dublin recently adduced a defence that had probably never been attempted before that he was a case of transposition of the viscera and therefore incapable of a normal degree of self control.¹ He was 28, and for about eighteen months had been keeping company with a widow of 35, to whom he was passionately attached. He was drawing a small wage as a chemist's assistant, and had just failed to pass an examination which would have advanced him professionally. In a field which the couple used to frequent they had—according to the accused—a quarrel but of an unimportant kind. The woman spoke of leaving him, there was some sort of a struggle in which they both lost their footing and he found his hands round her throat and, without being able to control what he was doing, continued to squeeze it until she lost consciousness. He then felt the heart, drained the body some distance by the hands, and repeatedly kicked the face, breaking the bones. He made no serious attempt to divert suspicion from himself. He maintained that he had never intended to do her any harm and that something had snapped in his brain.

A general practitioner of Ballymun, Dr John Hannan gave evidence that he had known the accused from his youth

¹ Dublin Evening Herald, Oct. 18-22.

and that the mother had consulted him because her son had been backward and solitary. He said that the lad's physical development had been poor and he had complete transposition of the viscera. Dr. Hannan maintained that this rare condition was often associated with mental deficiency, and put forward the theory that it was a sign of a throwback to a more primitive type of ancestor, and that a person affected by it could therefore not be expected to have the same restraint over his emotions as an ordinary person. He declared his belief that the accused at the moment of the murder had been temporarily insane and reverted to a jungle type. The prison medical officer, Dr. T. Murphy, confirmed the transposition but said that this abnormality, though rare, had no significance and was found in perfectly healthy people.

The judge directed the jury that there had been no evidence of provocation, and so the defence of manslaughter, on which the accused also relied, would not stand. Moreover, no reasonable jury could in his opinion accept any of the evidence tending to show insanity. Some people did insane things from time to time under the stress of emotions or passion, but their lack of self-control did not absolve them from responsibility in law for their acts. To prove insanity an accused person must show that because of a defect of reason he did not know what he was doing, or did not know that it was wrong (the M'Naghten rules); otherwise he was responsible. The jury, after an absence of an hour and forty minutes, came back with a verdict of guilty and a strong recommendation to mercy. The sentence of death has since been commuted to penal servitude for life.

Universities and Colleges

UNIVERSITY OF LONDON

H. F. T. Deane has been approved at the examination for the Academic Postgraduate Diploma in Medical Radiology.

UNIVERSITY OF MANCHESTER

William Francis Nicholson, M.D., M.Chir., F.R.C.S., has been appointed Lecturer in Surgery in the University.

UNIVERSITY OF LEEDS

The Council of the University has appointed Thomas Duncan Day, M.D., as Senior Research Fellow in Experimental Pathology and Cancer Research.

UNIVERSITY OF BRISTOL

D. M. P. R. Clarke has been approved in Part II of the examination for the Diploma in Medical Radiodiagnosis.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the College held on Dec. 15, with Mr. Frank E. Jardine, President, in the chair, the following, having passed the requisite examinations, were admitted Fellows:

T. M. Abbas, S. Abel, A. F. Alexander, P. St. G. Anderson, R. W. Bailie, J. A. Barclay, A. E. Bateman, H. A. Benjamin, C. L. Beynon, S. C. Bhattacharyya, H. G. Biggart, H. D. W. Black, J. S. Boyd, I. Bruce, A. Buchan, G. Buchanan, J. S. Calnan, J. D. Cameron, J. A. Campbell, N. A. Campbell, J. S. Cason, Z. A. Choudhuri, K. S. Clarke, K. W. Cochrane, R. B. G. Cook, J. W. Cowie, C. S. Dafae, K. H. Dalrymple, W. J. Dempster, W. R. Dickle, C. A. P. Donaldson, A. G. Gibb, C. A. Gleadhill, A. G. Gray, L. M. Green, W. S. Hanna, P. Harris, A. R. Harper, C. J. Hassett, J. R. Hochhauser, V. S. Hughes-Davies, R. F. Jackson, E. W. Jeyaratnam, A. Joffe, A. M. Keith, J. R. Kenyon, D. R. Kilgour, S. S. Kfirane, A. P. Kitchin, J. W. Knox, T. Koonvisal, D. W. Lamb, A. S. Lewis, R. A. Lindsay, Ursula M. Lister, H. K. Lucas, J. T. Mair, R. N. G. Majumder, T. S. Matheson, A. J. M. Mathieson, A. B. May, R. K. Menda, I. H. Meyer, A. M. Michael, J. P. Mitchell, R. Morrison, J. Mowat, A. A. Murray, J. H. McBeath, R. J. M. McCormack, A. B. McCulloch, D. M. Macdonald, G. H. D. McNaught, C. G. Nairn, J. G. Napier, E. L. Nicolson, T. H. Norton, W. D. Paterson, B. H. Price, Ghias-Ud-Din Qazi, P. T. Quinlan, M. S. Qureshi, Florence C. R. Richardson, E. F. Ridley, L. R. Robson, P. E. Roland, N. Rosenzweig, A. M. Sadek, H. K. Sarkar, A. S. Scott, L. S. Scott, R. H. Sewell, Shrikrishna, J. J. Skapinker, A. D. Smit, P. H. E. Smith, E. F. G. Stewart, B. A. Thompson, G. R. Thomson, N. Tunnell, P. R. Walbaum, R. B. Watson, Catrin M. Williams, R. G. Williams, Eileen D. M. Wilson, D. Wright, J. H. Wrigley, S. Zinn.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

Dr. H. C. Cameron, F.R.C.P., will deliver the Dr. John Burns Lecture in the Hall of the Faculty (242, St. Vincent Street, Glasgow) on Wednesday, Jan. 12, at 5 p.m. The title of the lecture is "The Beginnings of Modern Surgery, with personal recollections of Lord Lister." All medical practitioners are invited to attend.

Medical News

Inquiry into Punishment

The Home Secretary has appointed a committee to review the existing methods of punishment in prisons, Borstal institutions, approved schools, and reform homes (other than corporal punishment in prisons and Borstal institutions); to consider the procedure adopted in inquiries into breaches of discipline; and to recommend whether changes in methods and procedure are necessary or desirable. The members are Mr. H. W. F. Franklin (chairman), head master of Epsom College; Mrs. D. M. Bates, chairman of Leicester City Probation Committee; Dr. R. D. Curran; Mr. J. C. Jolly, K.C. Recorder of Preston and member of the Home Office advisory council on the treatment of offenders; Sir Leo Page, member of the Home Office advisory committees on probation and treatment of offenders; and Mr. E. V. Watering, member of the National Union of General and Municipal Workers. The joint secretaries are Mr. D. Pettigrew, of the Prison Commission, Horseferry House, Thorne Street, London, S.W.1, and Mrs. M. G. Kewley, of the Children's Department, Home Office, S.W.1. Anyone interested in the work of the committee is invited to communicate with one of the secretaries.

Dr. Curran, who is an authority on the medical aspects of crime, holds the post of psychiatrist at St. George's Hospital. He qualified in 1927, taking the Cambridge degree and the M.R.C.P. a year later, and the D.P.M. in 1930. He was elected F.R.C.P. in 1937. He served throughout the recent war in the R.N.V.R. as Consultant in Psychiatry.

Lock on Dangerous Drugs

New regulations made by the Home Office make it the duty of doctors, chemists, and other authorized persons to take proper care of dangerous drugs. The Home Office states that the courts will determine in any individual case what degree of professional necessity would justify an authorized person in carrying or leaving unattended a dangerous drug which is not in a locked receptacle, but there would seem to be no need for the prosecution to prove negligence where drugs are found otherwise than in a suitable receptacle. The Home Secretary is advised that a car cannot be regarded as a receptacle.

Administration of Water Undertakings

The Ministry of Health has issued a new version of its "Memorandum on the Safeguards to be Adopted in Day-to-Day Administration of Water Undertakings" (H.M.S.O. 2d.). It has been revised in the light of recommendations of the Gathering Grounds Subcommittee of the Central Advisory Water Committee. Where the water supply comes from the headwaters of the stream or an intake near the source, the water undertakers should if possible obtain control of the gathering ground above the dam or intake and so manage the land as to prevent pollution. When control of the gathering ground cannot be obtained, the water undertakers should frequently inspect it and seek the co-operation of farmers and house holders there, as well as of the local authority, to ensure that sewage and manure are properly disposed of.

Wills

Dr. Charles Morley Wenyon, late Director-in-Chief of the Wellcome Research Institution, left £6,593. Dr. Francis Benjamin Sutherland, formerly deputy commissioner of the General Board of Control for Scotland, left £8,358. Miss Eugenie Leeson Willis F.R.C.S., who was chief assistant to the orthopaedic department at the Manchester Royal Infirmary, left £2,656.

COMING EVENTS

Society of Medical Officers of Health

The second annual dinner of the Services Hygiene Group of the Society of Medical Officers of Health will be held at the Quadrant Restaurant, 74, Regent Street, London, W., on Friday, Jan. 28, at 7 for 7.30 p.m., with the president, Colonel H. D. Chalke, in the chair. All past and present hygiene officers of the Services are cordially invited, whether members of the society or not. Applications for tickets (13s. 6d., including gratuities but exclusive of wines) should be sent with remittance to the honorary secretary, Dr. G. M. Frizelle, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1, as soon as possible. Dress: dinner jackets with decorations.

Ophthalmological Congress

The Annual Congress of the Ophthalmological Society will be held at the Royal Society of Medicine, 1, Wimpole Street, London W.1, on March 31 to April 2, 1949. The subject for discussion will be "Corneal Grafting," which will be opened by Dr. R. Townley.

Paton (New York), Professor A. Franceschetti (Geneva), Professor G. P. Sourdille (Nantes) and Mr. J. W. Tudor Thomas (Cardiff). Members who wish to take part in the subsequent discussion are advised to intimate their intention before the opening of the Congress. Members wishing to read papers are asked to send the titles to Mr. Bridgeman as soon as possible. Abstracts of papers should be submitted not later than Jan. 31, 1949. The annual dinner will be held on March 31.

Neurological Congress

The 4th International Neurological Congress will be held in Paris on Sept. 5-10, 1949. Scientific business will comprise discussions on four main topics: (1) the thalamus and its pathology, (2) electro-encephalography and electromyography, (3) virus diseases of the nervous system, (4) the surgery of pain. Short papers on any neurological topic will also be given, and members are invited to submit by Feb. 1, 1949, titles and an abstract of their communication to the secretary (Dr. Macdonald Critchley, the National Hospital, Queen Square, London, W.C.1). The length of the communication must not exceed ten minutes. No member may give more than two communications. Application for membership and all financial contributions must be made through the national committee for each country, which will transmit all applications for membership and all subscriptions to the General Committee in Paris. There are two classes of members: (1) full members—i.e., all medical men or women interested in neurology, and (2) associate members—i.e., non-medical men or women interested in the Congress. Every member of the Section of Neurology of the Royal Society of Medicine is invited to contribute the sum of 10s. towards the general expenses of the Congress (whether attending or not). The subscription for full members is £2.10s. and for associate members £1.5s. All cheques should be made payable to the Treasurer, International Congress, and sent to Dr. M. J. McArdle, 52a Wimpole Street, London, W.1, before April 1, 1949.

APPOINTMENTS

J. D. W. Pearce, M.D., F.R.C.P., D.P.M., has been appointed Assistant Physician to Department of Psychiatry, St. Mary's Hospital, London, W.

Dr. Pearce qualified at Edinburgh University in 1927, and after taking the D.P.M. in 1930 proceeded M.D. in 1933. He took the M.R.C.P. in the same year, and was elected to the Fellowship in 1937. Dr. Pearce has been specially interested in the psychological problems of delinquency and has contributed to the medical press on the subject.

Robert Barer, M.B., B.S., of the Department of Human Anatomy in the University of Oxford has been appointed Alan Johnston Lawrence, and Moseley Research Fellow of the Royal Society for two years from Jan. 1, renewable for a further three years.

Dr. Barer took the London M.B., B.S. with honours in 1942 at University College Hospital and has worked on phase-contrast microscopy, publishing a paper on the subject in the *Quarterly Journal of Microscopical Science* in 1947. He served in the R.A.M.C. during the war and was awarded the Military Cross. He will continue his work at Oxford on the biological and medical applications of new methods of microscopy with special reference to the Burch refraction microscope.

CLIVE F. TEMPLE, M.B., B.S., Acting Honorary Medical Director of the British Legion Village.

SOCIETIES AND LECTURES

Monday

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, London, W.—Jan. 10, 8.30 p.m. "Treatment of Osteo arthritis of the Hip and Knee." Discussion to be introduced by Messrs W. G. Waugh and W. A. Law.

WESTMINSTER HOSPITAL SCHOOL OF MEDICINE Meyerstein Lecture Theatre, Horseferry Road, London, S.W.—Jan. 10, 5.30 p.m. "Cancer of the Pharynx and Oesophagus." Clinico-pathological demonstration.

Tuesday

CHELSEA CLINICAL SOCIETY—At South Kensington Hotel, 47, Queen's Gate Terrace, London, S.W.—Jan. 11, 7 for 7.30 p.m. General meeting. "Radioactive Isotopes in Treatment." Discussion to be opened by Drs. D. W. Smithers and W. V. Mayneord.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Jan. 11, 5 p.m. "Histopathology of the Skin." By Dr. I. Muende.

INSTITUTE OF UROLOGY—At St. Paul's Hospital, Endell Street, London, W.C.—Jan. 11, 11 a.m. "Anorectal Gonorrhoea." By Dr. A. H. Harkness.

PHYSIOTHERAPISTS ASSOCIATION OF GREAT BRITAIN—At Charing Cross Hotel, Strand, London, W.C.—Jan. 11, 8 p.m. "Physiotherapy and Its Uses in Postural Deformities." By Dr. Edward Moore.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Jan. 11, 5 p.m. "The Cardiology of Old Age." Goulstonian Lecture by Dr. C. J. Gavey, F.R.C.P.

Wednesday

INSTITUTE OF UROLOGY—At St. Paul's Hospital, Endell Street, London, W.C.—Jan. 12, 11 a.m. "Fungus vaginitis." By Dr. W. N. Mascall.

LONDON UNIVERSITY, Senate House, W.C.—Jan. 12, 5.20 p.m. "The Influence of General Health Superstitions on the Frequency of Dental Caries in Groups of Norwegian Children." Special University Lecture by Professor G. Toverud, Director of the Department of Pedodontia in the Dental School, Oslo.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, 242, St. Vincent Street, Glasgow—Jan. 12, 5 p.m. "The Beginnings of Modern Surgery with Personal Recollections of Lord Lister." By Dr. H. C. Cameron.

SOCIETY OF CHEMICAL INDUSTRY—Joint meeting of the Microbiological Panel of the Food Group and the Society for Applied Bacteriology, at Medical Society of London, 11, Chandos Street, W.—Jan. 12, 2.15 p.m. "Microbionics and the Growth of Fermenting Crops." By Dr. M. C. Rayner. "Micro organisms in Relation to the Production and Degradation of Soil Organic Matter." By Dr. G. K. Frazer. "Soil Antibiotics." By Dr. P. W. Brian. Discussion.

SOUTH WEST LONDON MEDICAL SOCIETY—At Bellinghale Hospital, Wardsworth Common, S.W.—Jan. 12, 8.15 p.m. "Diagnosis and Treatment of Acute Mastoiditis." By Dr. W. A. Harvey.

Thursday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Jan. 13, 5 p.m. "The Influence of Stress in Dermatology." By Dr. H. W. Barber.

INSTITUTE OF UROLOGY—At St. Paul's Hospital, Endell Street, London, W.C.—Jan. 13, 11 a.m. "Gonococcal Infections of the Urinary Tract." By Dr. A. H. Harkness.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN—At 17, Bloomsbury Square, London, W.C.—Jan. 13, 7.0 p.m. "London and Pharmacy in the Seventeenth Century." By Arthur Loftham, Ph.D.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Jan. 13, 5 p.m. "The Cardiology of Old Age." Goulstonian Lecture by Dr. C. J. Gavey, F.R.C.P.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—At Large Lecture Theatre, Jan. 13, 4.0 p.m. Lecture-demonstration: Neurology.

Friday

LONDON CHEST HOSPITAL, Victoria Park, E.—Jan. 14, 5 p.m. "The Application of Collapse Therapy in Pulmonary Tuberculosis." By Dr. N. Lloyd Rusbv.

MAIDA VALE HOSPITAL MEDICAL SCHOOL, Maida Vale, London, W.—Jan. 14, 5 p.m. Case demonstration by Professor S. Nevin.

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh—Jan. 14, 8 p.m. Address by Mr. I. M. Duthie.

WEST KENT MEDICO-CHIRURGICAL SOCIETY—At Miller Hospital, Greenwich High Road, London, S.E.—Jan. 14, 8.30 p.m. Clinical meeting.

Saturday

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION—At Royal Free Hospital, Gray's Inn Road, W.C.—Jan. 15, 3 p.m. Clinical meeting.

BIRTHS, MARRIAGES, AND DEATHS

BIRTH

Fisher—On Dec. 29, 1948, at St. George's Hospital to Mary (Pepper) a son of Dr. R. E. W. Fisher and a daughter.

MARRIAGE

Habibis—Murray—On Dec. 29, 1948, at St. Mary and the Angels, Byrom Street, W. Homer A. Habibis, M.D., D.C.H., of 14, Portchester Terrace, London, W., and Stella Mary Murray, M.B., B.S., D.C.H., elder daughter of Mr. and Mrs. J. A. Murray of Streifford House, Brighton Road, Sutton, Surrey.

DEATHS

Abernethy—On Dec. 26, 1948, at 54, Queens Crescent, London, N.W. Victor Alexander Abernethy, L.R.C.P.S.D. and L.M.

Aldridge—On Dec. 26, 1948, at Bournemouth, Charles Braxton Mooring Aldridge, M.R.C.S., L.R.C.P., of Chifford, 100, Richmond Park Road, Bournemouth, aged 71.

Anderson—On Dec. 22, 1948, at 3, Victoria Park Gardens, South Glasgow, Arthur Anderson, M.D., D.P.H., aged 63.

Balthazar—On Dec. 29, 1948, Ewald Mount Balthazar, M.R.C.S., L.R.C.P., D.P.H., of 492, Lea Bridge Road, Leyton, E.

Dockray—On Dec. 29, 1948, John Vernon Dockray, O.B.E., M.R.C.S., L.R.C.P., of Stradbroke, near Diss, Norfolk.

Foulkes—On Jan. 2, 1949, at Glen Heollog, Aberystwyth, Meredydd Foulkes, M.R.C.S., L.R.C.P., aged 62.

Garrad—On Dec. 26, 1948, Francis William Garrad, M.D., of 40, Cobden Road, Harrogate, aged 78.

Hollway—On Dec. 26, 1948, at Teignmouth Hospital, Edith May Hollway, O.B.E., M.B., B.S., of St. Anthony, Bournemouth, Dorset.

Hutchinson—On Dec. 25, 1948, at Worthing, Richard Cecil Hutchinson, M.D., D.P.H.

Mackay—On Dec. 28, 1948, at Chichester, James Murdoch Mackay, M.C., M.B., Ch.B., late West African Medical Service.

Miller—On Dec. 23, 1948, at St. Mary's Hospital, London, W. Reginald Henry Miller, M.D., F.R.C.P., of 32, Abbey Gardens, London, N.W.

Mold—On Dec. 24, 1948, at Orchard Leigh, Eastington, Gos. George Henry Chivass, M.D., M.B., Ch.B., late of Cross-in-Hind, Sussex, aged 64.

Mossman—On Dec. 24, 1948, at Balddreud, Pajochy, Perthshire, Robert Arthur Mossman, L.R.C.P.S.D., aged 94.

No. 51

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Dec. 18.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included) (b) London (administrative county) (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* there was a decrease in the notifications of measles 294, whooping-cough 51, diphtheria 20, and dysentery 15. There were increases in the incidence of acute pneumonia 55 and scarlet fever 16.

The largest decreases in the notifications of measles were Lancashire 145, Yorkshire West Riding 126, Essex 86, and Middlesex 68; the largest increases were Durham 65 and Worcestershire 56.

The largest rises in the incidence of whooping-cough were Kent 55 and Sussex 40; the greatest fall was London 33. The chief features of the returns for diphtheria were an outbreak with 8 notifications in Yorkshire East Riding, Holderness R.D., and an increase of 8 in Essex. The largest increase in the incidence of acute pneumonia was in the south-eastern counties, where the notifications rose from 66 to 105.

The largest centres of dysentery were London 8 (Hackney 4) and Lancashire 8 (Liverpool C.B. 7). The largest return for acute poliomyelitis was Yorkshire West Riding 3.

In *Scotland* increases were recorded in the notifications of acute primary pneumonia 54 and whooping-cough 19, while a decrease of 67 was reported for measles. The rise in the incidence of pneumonia was contributed by the western area of the country.

In *Eire* there was an increase of 9 in the notifications of measles and a decrease of 12 for whooping-cough.

In *Northern Ireland* the chief feature of the returns was a decrease of 26 in the notifications of measles in Belfast C.B.

Quarterly Returns for England and Wales

During the September quarter the birth rate was 17.6 per 1,000, compared with 20.0 for the corresponding quarter of 1947. The infant mortality rate was 28 per 1,000 live births, and was the lowest rate ever recorded for any quarter and 4 below the rate for the third quarter of 1947. The stillbirth rate was 22.6 per 1,000 total births and was the lowest rate for any quarter on record. The general death rate was 9.3 per 1,000 and 0.4 above the rate for the corresponding quarter of the preceding year.

Quarterly Return for Eire

The birth rate during the September quarter was 21.9 per 1,000 and was 1.5 below the rate for the third quarter of 1947. The infant mortality rate was 38 per 1,000 registered births, and was the lowest rate yet recorded. The general death rate was 10.5, and was 0.7 below the rate for the September quarter of 1947. The death rate from the principal epidemic diseases was less than half the recent rates for the third quarters; only 125 deaths were attributed to these causes, and of these 69 were due to infantile diarrhoea and enteritis and 42 to whooping-cough. Deaths from pulmonary tuberculosis numbered 512, and deaths from other forms of tuberculosis 167; these were, respectively, 124 and 52 fewer than in the third quarter of 1947.

Week Ending December 25

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,154, whooping-cough 1,791, diphtheria 100, measles 8,959, acute pneumonia 792, cerebrospinal fever 22, acute poliomyelitis 17, dysentery 30, paratyphoid 3, and typhoid 4.

The Ministry of National Insurance states that some people may get reduced sickness and unemployment benefit from Jan. 3. These are people who were already insured when the new scheme came into operation but whose total number of contributions paid or credited for the year ended July, 1948, including arrears paid since then, was less than 50. For instance, a man with less than 26 contributions paid and credited in this period will not be entitled to benefit, but if he has more than this number the weekly rate will vary from 13s. with 26 to 29 contributions to 25s. with 48 or 49 contributions. Similar reductions will be made for dependants' benefits. Benefit may also be lost after Jan. 3 by those who have not yet handed in their 1947-8 contribution cards. Anyone who still has this card in his possession is advised to take it at once to the employment exchange and get it replaced by a National Insurance card.

AT THE FIRST GASP

Clinical experience has amply confirmed original reports on the value of 'Neo-Epinine' in the treatment of bronchial asthma. Equal to adrenaline and superior to ephedrine in anti-asthmatic activity, it is relatively free from the undesirable side-effects of both these drugs. 'Neo-Epinine' is administered simply, either sublingually or by oral inhalation, thereby avoiding the necessity for injection. Issued for sublingual administration as compressed products each containing 20 mgm., in bottles of 25 and 100; and as 1 per cent Spray Solution in bottles of 10 c.c.

'NEO-EPININE'

ISOPROPYL ADRENALINE SULPHATE

BURROUGHS WELLCOME & CO. (The Wellcome Foundation Ltd.) LONDON

THE self-imposed arbitrary standard set for London Hospital Catgut at its inception is above that of the B.P. Codex and the U.S.A. Pharmacopoeia. The London Hospital standard has never been departed from and is still maintained.

This outstanding feature, together with an

elasticity (elongation) approximating 40%, affords the Surgeon perfect safety in using fine sizes compatible with modern technique.

When using London Hospital Catgut, we strongly recommend Surgeons to use B.P.C. sizes 2/0, 0, and 1 for general surgery and B.P.C. sizes 3/0 and 4/0 for very fine work.

THE LONDON HOSPITAL (LIGATURE DEPARTMENT), LTD., LONDON, E.1, ENGLAND

TRADE MARK

THEOGARDENAL

theobromine and phenobarbitone

BRAND

tablets

The vaso-dilator and diuretic actions of theobromine and the sedative effect of phenobarbitone are combined in an effective synergistic form in 'Theogardenal'.

It is of great value in the symptomatic relief of hypertension. In therapeutic dosage it is non-toxic, has no cumulative effect and is well tolerated even when prescribed over lengthy periods.

tablets: (theobromine gr. 5 and phenobarbitone gr. $\frac{1}{2}$)

For the 'bilious' or 'liverish' patient

Dehydrocholin B.D.H. is dehydrocholic acid, the most active and least toxic of the bile acids. It is highly effective in aiding the digestion and absorption of foodstuffs, particularly fats, and it promotes the secretion of bile, thus exerting a twofold action. Dehydrocholin B.D.H. is effective by mouth and is indicated particularly for the treatment of 'bilious' or 'liverish' conditions.

Available in tablets each containing 0.25 gramme.

DEHYDROCHOLIN B.D.H.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Oestrogen Estimation

Q.—What is the method of estimating oestrogen in urine and for what purpose is it used?

A.—Many methods have been, and still are being, used, and none can be regarded as satisfactory. Most of them consist basically in extracting the oestrogens with ether from a 24-hour specimen of urine. Thorough hydrolysis is also necessary to break up the oestrogen-glucuronic-acid combinations. The fraction containing the oestrogens is then usually assayed according to its ability to produce cornification of the vaginal epithelium in spayed female mice or rats. Colorimetric and photometric tests have also been described (Bachman, K., *J. biol. Chem.*, 1939, 131, 455), but they are rarely employed.

It is relatively easy to demonstrate the presence of oestrogens but extremely difficult to make an accurate quantitative determination. Biological assays are notoriously unreliable, because the reactions in the test object vary with the sensitivities of individual animals of the same species, the spacing of doses, etc. Also the different excretion products (for example, oestrone, oestriol) of oestradiol have different biological activities, and the total effect depends on their relative proportions. Again, not all workers employ the same criteria for a positive biological response, and it is doubtful whether the findings of one laboratory can be compared with those of another. Apart from the technical difficulties in quantitative work, its value in clinical practice is doubtful at present. The amount of oestrogen in the urine does not necessarily reflect the blood level; indeed it is possible that one might be high when the other is low. Moreover, oestrogen is excreted by other routes—for example, in the bile and faeces. The state of liver and renal function also affects the oestrogen content of the urine. Although quantitative estimations have been used in the hope of determining the level of ovarian and placental function, and particularly in such conditions as amenorrhoea, pregnancy toxæmia threatened abortion, and pregnancy complicated by diabetes such studies should still be regarded as experimental rather than of general practical application. Apart from rough qualitative tests of blood and urine, often the best practical method of estimating oestrogen production is to note the effects on the vagina and endometrium of the patient rather than on the genital tract of a test animal.

Skin Sterilization

Q.—Is it possible to render the skin bacteriologically sterile? Is surgical spirit a reliable cleansing agent? Please comment also on the use of the following "dettol," tincture of iodine "cetavlon," methylated ether. Would repeated application succeed where a single application has failed?

A.—The skin cannot be sterilized. Its "resident" flora is partly inaccessible: it is possible to destroy only the "transient" or purely superficial flora, which may include pathogens. Most of the disinfectants named, if properly applied, are capable of this, including spirit, which according to G. T. L. Archer (*British Medical Journal*, 1945, 2, 148) is superior to ether. Tincture of iodine is perhaps the most reliable and rapidly acting; further experiments illustrating this have recently been made by Gardner (*Lancet*, 1946, 1, 683; 2, 760), whose work also includes observations on "dettol" and "cetavlon." These papers should be consulted for further information. If skin is prepared for operation some time beforehand, different considerations apply, and the choice may reasonably fall on a slowly acting but persistent disinfectant such as mercury perchloride or one of the antiseptic dyes or flavines. It is impossible to say which of all these procedures is the most satisfactory: no practical comparative tests on a large enough scale have ever been made, and the incidence of operation-wound infection is affected by so many other factors that any information so obtained would be of doubtful significance.

Transfusion of Infected Blood

Q.—Is there a method of sterilizing blood from (1) *potentially malarious* and (2) *potentially syphilitic* donors?

A.—(1) The danger of transmitting malaria occurs only when red cells are being transfused. If blood suspected of containing malaria parasites is stored for 14 days at 4° C. the majority of the plasmodia will almost certainly be destroyed or rendered non-infective. Antimalarial drugs such as quinine or mepacrine, if added to the blood, will destroy parasites, but the mixture must be kept at 37° C. for at least 24 hours, by which time some degree of haemolysis may have occurred, thus rendering the red cells unsuitable for use. Proguanil ("paludrine") has no direct action on the malarial parasites. Infections due to *Plasmodium falciparum* usually die out two years after a patient has left a malarial country; *P. vivax* and *P. malariae* may persist in the tissues for many years. If it is suspected that blood containing malaria parasites has been used for transfusion, the recipient should be placed on suppressive doses of an antimalarial drug—proguanil 100 mg. daily, or mepacrine 100 mg. daily, or chloroquine 300 mg. on one day a week. Such suppressive regimens, so long as they are continued, will usually prevent the onset of acute symptoms.

(2) *Treponema pallidum* may be transmitted in whole blood, plasma, or serum. In latent syphilis or in late tertiary syphilis it is doubtful whether spirochaetes are present in the blood stream, but in the incubation period and during the primary and secondary stages there is danger of transmitting infection by transfusion. Spirochaetes may be destroyed *in vitro* by the action of arsenicals, arsenious oxides such as "mapharsen" acting more rapidly than neoarsphenamine. H. Eagle and W. Mendelsohn (*Science*, 1938, 87, 194) point out that the antispriochoetal action of arsenicals *in vitro* depends on a number of variables. Raising the temperature from 23° to 37° C. increases the rate of inactivation, but serum and tissue cells retard the spirochaetocidal effect. It is therefore doubtful whether this measure could be applied to whole blood. Penicillin inactivates *Treponema pallidum* in a concentration of 10,000 units per ml. when the spirochaetes are exposed for three hours at 37° C. (A. Bessemans and R. Derom, *Ann. Derm. Syph. Paris*, 1946, 6, 744). H. Eagle (*J. Bact.* 1946, 52, 81) has shown that penicillin G is more active in destroying *T. pallidum* than the other forms of penicillin; the relative activities per mg. of the penicillins are: F=53, G=100, K=76, X=51. No reliable evidence is available to show how much time is required to inactivate treponemata in whole blood.

Glaucoma Simplex

Q.—Is there anything to prevent the intense irritation of the eyes and the surrounding skin which may be due to the application of pilocarpine in oil to a patient with glaucoma simplex?

A.—It is likely that the irritation is due to the medicament. Some patients develop these irritative symptoms after prolonged use of almost any type of drops. Oily drops are apt to be more irritating than a watery solution, and higher concentrations than lower concentrations. The patient is presumably using 0.25% pilocarpine in oil. Drops of 0.5% in watery solution three or four times a day may be better tolerated. Alternatively, eserine drops 0.25% in watery solution may also prove the better medicament. The important thing in using drops is, of course, to keep the pupil contracted and the tension under control. This, rather than tolerance to the drops, should determine whether the best procedure would not be surgical.

Fanconi's Syndrome

Q.—What is Fanconi's syndrome, and what are the differential diagnosis and treatment?

A.—There are two separate and distinct disorders known as Fanconi's syndrome. In chronological order these are: (1) the combination of congenital hypoplasia of the bone marrow with multiple congenital defects occurring as a familial disease (*Jb. Kinderheilk.* 1927, 117, 257); (2) a condition in which dysfunction of the renal tubules is associated with a hypophosphataemia, renal glycosuria, "rickets," and disturbance of amino-acid metabolism (*Jb. Kinderheilk.* 1931, 133, 199; *Disch. med. Wschr.* 1936, 62, 1169; *Jb. Kinderheilk.* 1939, 141, 199).

There is no purpose in discussing the details of differential diagnosis and treatment of these two widely different syndromes, but the questioner will find the information he requires in the papers cited.

T.A.B. in Cheiropompholyx

Q.—What are the rationale and method of administration of T.A.B. in the treatment of cheiropompholyx?

A.—There is no rationale for the use of T.A.B. in pompholyx; it is shock therapy and empirical. It may be given intravenously in a dosage of 100 million organisms, when a severe pyrexial reaction lasting a few days may be anticipated, or in a dosage of 10 million repeated a few times at weekly intervals, when a less severe reaction will result.

Hormone Treatment of Infertility

Q.—Is testosterone propionate or methyl testosterone indicated, and, if so, in what dosage, for infertility in a man aged 41? His testes are abnormally small, and an examination of the seminal fluid reveals no spermatozoa. There is no other physical abnormality and no history of previous illness.

A.—Testosterone propionate or methyl testosterone has been advocated for infertility associated with oligospermia or even azospermia, because experimentally either maintains spermatogenesis in the hypophysectomized animal. The dosage might be in the neighbourhood of 25 mg. of the former injected three times a week, or 5 mg. of the latter thrice daily. The writer, however, has no confidence in this therapy, or even in gonadotrophin therapy, unless there is at the same time clear endocrinological evidence that the condition is secondary to a hypopituitarism. Testicular biopsy should be carried out in every case, and it is probable that in this case fibrosis and hyalinization (resulting from previous virus infection) will be found; such a condition would not respond to any hormone therapy.

Melanoma

Q.—A man aged 57 has had from childhood a small area of black pigmentation about 5 cm. to the right and slightly below the umbilicus; it is now about 1 cm. across. The skin is freely movable and there is no proliferation of tissue. In view of the risk of malignant change, what advice should be given? Would removal provoke malignant development?

A.—The relationship between benign and malignant melanoma is of great importance. Signs of malignant change developing are an increase in size, increase in the degree of pigmentation, the presence of moisture, and the occurrence of bleeding. When any of these signs are present in a benign melanoma it must be excised carefully. Experience proves that trauma to a benign melanoma can initiate malignant changes, and when such a tumour is subjected to constant trauma it must be excised. When excision is undertaken certain technical details are important. Excision is carried out with the scalpel; the tumour itself must not be touched by the scalpel or forceps, or traumatized in any way. The encircling incision must be placed at least 2.5 cm. from the edge of the tumour, and the underlying deep fascia is also removed over an area 4 cm. from the edge.

Secondary Syphilis

Q.—A patient developed a secondary syphilitic rash and was treated with 14 mega units of penicillin over 14 days. She has had an intermittent course of arsenic and bismuth (0.6 g. and 2 ml. a week for three 12-week courses), but the injections upset her. Her blood was positive at the start, but she has since had three negative Wassermann reactions. Is it safe to discontinue the arsenic and bismuth when she has completed her fourth 12-week course (she has one month's rest in between courses) or should I go on for another full twelve months?

A.—The treatment already given seems quite adequate, and as injections upset the patient further treatment might do more harm than good. It will, of course, be necessary to keep the patient under observation with periodical blood tests (say three-monthly for the first year and six-monthly for the second year) for two years after completion of treatment; the cerebrospinal fluid should be examined some time during the observation

period. Should the question of pregnancy arise, careful observation throughout and perhaps a second course of penicillin would be indicated.

Enteroptosis

Q.—Is there any recent treatment for enteroptosis? The x-ray report is as follows: "Enteroptosis and irregular spasm of lower part of colon; pelvic colon somewhat elongated; weak contractions of caecum and ascending colon."

A.—Enteroptosis needs no treatment. A low position of the viscera is merely part of a lean asthenic habitus and there is no evidence that it is responsible for any symptoms. Exception must be made to this statement in the case of the kidney, where kinking of the ureter may occasionally give rise to a Dietl's crisis, and possibly also in the case of the spleen. For the rest "visceroptosis" is no more than the usual position assumed by the viscera in the tall thin individual. The only comment of possible significance in the radiologist's report cited by the questioner is the presence of irregular spasm in the lower part of the colon. This may result in abdominal pain, and, if it indicates the spastic colon, treatment with a low-residue diet, liquid paraffin, and antispasmodics should be of benefit.

Fluorides in Prevention of Dental Caries

Q.—Would it be worth while for an adult who still has most of his teeth, though heavily filled, to try fluorine treatment in the hope of delaying the inevitable? If so, in what form and manner should it be used? Are there any contraindications?

A.—The evidence that topical application of fluoride solutions is of value in halting the onset of dental caries after the eruption of the teeth is not as yet entirely convincing. In the adult, provided that regular dental attention is received, the teeth are far less likely to be lost on account of dental caries than from gingivitis. The method so far used is the topical application of 2% sodium fluoride solution to the surfaces of the teeth, after previous cleaning and drying to ensure adequate contact of the solution with the dental tissues. The optimum concentration of the solution and the number and frequency of applications are not as yet known. It must be remembered that fluoride salts are extremely toxic. The questioner should also refer to a letter on this subject published in the *Journal* of Jan. 1 at page 29.

Petit Mal

Q.—Is anything known of the aetiology of petit mal, and is there any useful form of treatment?

A.—Petit mal is ordinarily a constitutional affection due to a cerebral dysrhythmia, often inherited. The latest form of promising treatment consists in giving capsules of "tridione", the usual dose being 0.3 g. thrice daily. Caution is necessary owing to the risk of agranulocytosis. A subjective sensation of glare, if not photophobia, is a very common side-effect.

NOTES AND COMMENTS

Correction.—Mr. Malcolm Donaldson (chairman of the Clinical Cancer Research Committee of the British Empire Cancer Campaign) has pointed out that in our report (Dec. 18, 1948, p. 1076) of the Committee's statistical survey of cancer of the kidney, bladder, and prostate it was stated that the first symptom of the disease (cancer of the prostate) was difficult or painful micturition in 60% of cases. What the Committee actually stated was that difficult or frequent micturition was the first symptom in 60% of cases. Local pain in the perineum or urethra was the first symptom in only 3.7% of the cases.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JANUARY 8 1949

THE SECRETARY REPORTS

SPENS REPORTS COMPARED

It may be useful to recall some of the recommendations of the two Spens Committees and to compare the effect of the two Reports when considered together. This comparison is of the Spens Committees' recommendations, whether or no they have been carried into effect. Each Committee was anxious that conditions in the field of practice with which it was concerned should be sufficient to attract the best practitioners. The Specialist Spens Committee's recommendations were therefore designed to remove some of the financial risks and deterrents which had previously been responsible for the loss of many potential specialists to general practice, while the General Practice Spens Committee proposed to improve substantially the prospects of attaining success in general practice lest the expected improvement of remuneration in the specialist field should attract the best members of the profession, leaving general practice to be recruited from the less able practitioners.

Both Committees appear to assume that one year will elapse after registration before the young practitioner begins his chosen career. The General Practice Committee proposes that "after the completion of house appointments" the doctor intending to take up general practice should spend one or preferably two years as assistant, while the Specialist Committee proposes for the potential specialist a series of hospital training appointments arranged in three grades covering six or seven years from the end of the first year after registration.

The young man of 25 who proposes to enter general practice will, according to the Spens recommendations, receive as assistant £500 the first year and £600 the second year, while the potential specialist will receive £600 the first year and £700 the second. Thereafter, the general practitioner will be free to assume the full responsibility of practice with a list of his own. The General Practice Report makes no special mention of the years between the ages of 26 and 30, but of the general practitioners of 30-34 years 57% may expect to receive between £700 and £1,300 and 31% over £1,300. The potential specialist will proceed through three grades of appointments by annual increases of £100, assuming that there is no delay in obtaining appointments, until at the age of 31 he is receiving £1,200. The figures relate to net income and to 1939 values.

Rewarding Ability and Effort

Both Committees seek a method of remuneration which will involve differentiation depending upon ability and effort. The General Practice Committee assumes a capitation method as meeting this requirement and permitting equal remuneration for equal burden of practice. The Specialist Committee recommends that the specialist from 32 to 40 years of age, who, although he has completed his training, is still increasing the variety and width of his clinical experience, should receive an automatic incremental basic scale of remuneration, and differentiation should be secured both during and after this period by certain distinction awards limited in number and amount for outstanding merit.

The comparative effect of the detailed recommendations of both Committees is illustrated in the following table. All incomes are net and in terms of 1939 values.

Incomes for Ages 30-64

Age	General Practitioners		Specialists	
	Range of Income	Additions	Basic Salary	Additions
30	10-5% receive under £700 p.a.			
31	22-3% " £700-£1,000		£1,500	
32	35% " £1,000-£1,300		£1,625	
33	17-8% " £1,300-£1,600		£1,750	
34	11-6% " £1,600-£2,000			
	2-7% " over £2,000			
35	6-6% " under £700 p.a.		£1,875	
36	16-6% " £700-£1,000		£2,000	
37	26-6% " £1,000-£1,300		£2,125	
38	26-9% " £1,300-£1,600		£2,250	
39	17-7% " £1,600-£2,000		£2,375	
	5-6% " over £2,000			
40-49	8% " under £700 p.a.	10% of principals receive fee of £100 p.a. for supervising assistants	£2,500	
	19-1% " £700-£1,000			
	23-4% " £1,000-£1,300			
	23-7% " £1,300-£1,600			
	16-7% " £1,600-£2,000			
	9-1% " over £2,000			
50-54	7-2% " under £700 p.a.	Grant for assistant if no assistant previously employed:		
	17-3% " £700-£1,000	1st year, £500		
	24-8% " £1,000-£1,300	2nd year, £500		
	23-7% " £1,300-£1,600	3rd year, £100		
	14-9% " £1,600-£2,000			
	12% " over £2,000			
55-59	20-4% " under £700 p.a.			
	15-8% " £700-£1,000			
	21-9% " £1,000-£1,300			
	21-5% " £1,300-£1,600			
	15-4% " £1,600-£2,000			
	5% " over £2,000			
60-64	17-4% " under £700 p.a.			
	23-2% " £700-£1,000			
	27-5% " £1,000-£1,300			
	17-9% " £1,300-£1,600			
	10-6% " £1,600-£2,000			
	3-4% " over £2,000			

The following comparisons may be drawn from the table:

(i) In the age group 35-39, over 53% of the general practitioners will receive between £1,000 and £1,600 and all specialists will proceed incrementally from £1,875 to £2,375.

(ii) In the age group 40-49, less than 25% of general practitioners will reach £2,000 and less than 10% will exceed £2,000. All specialists of the same age will receive a basic salary of £2,500.

(iii) The highest proportion of general practitioners to exceed the £2,000 level is 12% in the 50-54 age group. 100% of specialists receive the basic £2,500.

(iv) An additional means of income open to the general practitioner is to train an assistant, for which he is recommended to receive a fee of £100 per annum; this is available to 10% of practitioners. 34% of specialists may expect to receive a distinction award in addition to their basic salary.

(v) The distinction awards to specialists are permanent additions to the basic salary continuing until the holder reaches the retiring age of 65. The General Practice Committee expects that only 3% or 4% of practitioners between 60 and 64 years of age will receive over £2,000 and 40% will be receiving between £700 and £1,300. Theoretically the proportion of specialists of the same age group receiving £3,000 or more may be anything up to 34%, and none will receive less than £2,500.

The regulations which have so far been issued by the Minister of Health differ in some respects from the Spens recommendations. For example, there is no regulation that a newly qualified practitioner entering general practice must spend one or

two years as an assistant; he may establish himself immediately as a principal if he so desires. Neither do the regulations specify any proportion of principals who may supervise assistants.

The scheme of grants for supervision of the training of assistants which the Minister has introduced under the National Health Service Act provides a grant of £150 to the principal for the training period of one year plus the salary of the assistant and boarding expenses (together not exceeding £700 a year), with an allowance not exceeding £150 a year if an additional car is necessary.

Holidays and Locums

The Specialist Committee recommends that the specialist should be allowed definite holidays, and in addition extended

leave should be given on occasion for study and research. The specialist should not be financially liable for the provision of a deputy during such periods of absence. The General Practice Committee makes no mention of holidays, with or without the provision of a locum. It refers to postgraduate study only in connexion with the means of levelling up low incomes, and suggests that a bonus of £100 should be paid to a practitioner who had attended a refresher course within the preceding three years. The question of providing a locum is not mentioned. The scheme of grants for postgraduate courses introduced by the Minister provides for payment of the fees for approved courses, plus subsistence allowances of up to £1 a day if attendance entails absence from home at night, with first-class travelling expenses. In addition, up to 14 guineas a week is allowed for payment of a locumtenent where necessary.

National Health Service

AMENDING BILL FURTHER CHANGES SOUGHT

Some of the changes likely to be sought by the profession in the legislation amending the National Health Service Acts or in new regulations were listed in the *Supplement* of Dec. 18, 1948 (p. 225). Two points can be added to that list:

Foreign Visitors.—The Minister's view, with which Counsel consulted by the General Medical Services Committee has agreed, is that the services provided under the National Health Service Act for "the people of England and Wales" are available also for foreign visitors. In so far as the Act provides for the free treatment of foreign visitors, the Minister has been urged to exclude such provision when he introduces amending legislation.

Disciplinary Procedure.—An elaborate code has been established for safeguarding the interests of the patient. The disciplinary procedure set out in the Service Committees and Tribunal Regulations, 1948, is based largely on the National Health Insurance model. The regulations require (among other things) that any complaint by a person against a medical practitioner in respect of an alleged failure to comply with the terms of service shall be investigated by the Medical Service Committee. The new code, however, unlike the National Health Insurance code, contains no provision for the investigation of complaints by a medical practitioner about the conduct of a patient. The Medical Benefit Regulations made under the National Health Insurance Act, 1936, contained a provision requiring any question arising between an insurance practitioner and a person in respect of the conduct of the person while receiving treatment to be investigated by the Medical Services Subcommittee. The Minister has been asked to include a similar provision in the disciplinary arrangements under the new Service.

PRESCRIBING BY GENERAL PRACTITIONERS. GUIDANCE FROM MINISTRY

General practitioners are sometimes in doubt whether a preparation may be prescribed on Form E.C.10. If a practitioner orders preparations which are not drugs or medicines, the local executive council is empowered to recover from him the cost of such preparations. He may challenge the council's action and require the matter to be referred to the local medical committee under Regulation 16 of the National Health Service (Service Committees and Tribunal) Regulations, 1948 (*Journal*, April 3, p. 653), with the possibility of appeal to referees. The Minister has appointed a committee to decide on what should be classified as a drug or medicine, and he will also consult the Standing Medical and Pharmaceutical Advisory Committees of the Central Health Services Council as soon as these are set up. In the meantime he has sent two lists of preparations to local executive councils; they were drawn up by an advisory committee in relation to the National Health Insurance scheme.

The Ministry points out that the lists have no statutory force, were compiled nearly twenty years ago, and are not exhaustive. They are reproduced in the next column.

TABLE I.—*Substances and Preparations Which in the Opinion of the Advisory Committee Were Never Drugs*

Acidophilus milk	"Marmite"
"Albulactin"	Meat extracts (other than liver extracts)
"Allenburys Food"	Meat juices
"Ambrosia"	"Mellin's Food"
Arrowroot	"Melovol"
"Benger's Food"	"Midolia" biscuits
"Bovine Meat Juice"	"Muller's Nutrient"
"Bovril"	"New-Promonta"
"Bragg's Charcoal Biscuits"	"Numol"
"Brand's Essences"	Nutrient suppositories
Brandy	Oatmeal
"Bulgar-Lac"	"Ovaltine"
Calves' foot jelly	"Oxo"
Cane sugar	"Panopepton"
"Carnrick's Peptonoids"	Pearl Barley
Casein food	Peptonizing powders
"Casumen"	"Plasmon"
"Ceregen"	"Plasmon Oats"
"Cerialia Cream"	"Robinson's Barley and Groats"
Champagne	"Roboleine"
"Chy-mol"	"Saccharin tablets"
Coffee	"Sanaphos"
Diabetic bread and biscuits	"Sanatogen"
"Energen" bread and biscuits	"Savory and Moore's Food"
"Glaxo"	Sherry
"Glaxovo"	"Somatose"
Gluten bread	"Tonagen"
"Glyco-lactophos"	"Torbet's Lactic Oats"
"Herogen"	"Valentine's Meat Juice"
"Hi-g-ah Tea"	"Valkasa"
"Horlick's Milk"	"Vibrona"
Ice	"Vigoral"
"Instant Postum"	"Virol"
Iodized salt	"Virol and Milk"
Lactic milk	"Vitafer"
"Lacto-Dextrin"	"Vitagene"

Disputes in a particular case can be resolved only by the procedure laid down in the regulations referred to above. In particular, though only brandy, champagne and cherry are shown in Table I, the Minister considers that no alcoholic liquors should be ordered on Form E C 10, nor should toilet requisites.

SPECIALISTS' PERMANENT CONTRACTS LIMITED CIRCULATION OF PROPOSALS

The draft proposals for the permanent contracts for consultants and specialists were forwarded as a confidential document to the Consultants and Specialists Committee established by the British Medical Association, the Royal Colleges, and the Royal Scottish Corporations. A request was made to the Ministry that the document should be circulated to the Regional Consultants and Specialists Committees for their observations and recommendations. The Ministry, however, adheres to its view that the proposals are not ripe for wider publication and consequently this will have the effect of depriving the elected representatives of consultants and specialists in each region of official opportunity of expressing their views at this stage.

SUPPLEMENTARY OPHTHALMIC SERVICE SAMPLE INQUIRY

The Health Service has brought a tremendous demand from the public for ophthalmic treatment, and ophthalmic practitioners have had to work long hours to see all their patients. During the past few months the Ministry of Health has been receiving returns from local executive councils which indicate that considerable sums have been paid out to ophthalmic practitioners for work under the Supplementary Service. The question has been raised—presumably by the Treasurer—whether the fee payable to an ophthalmic practitioner for an eye examination is appropriate.

The fee was negotiated with the Ministry on the assumption that on the average each examination occupied about half an hour. The Ministry considers that with nearly six months' experience it should now be possible to ascertain whether that assumption has been borne out in practice. It therefore proposes to seek the co-operation of ophthalmic practitioners in carrying out a sample inquiry to determine the average time taken per examination.

If the inquiry shows that the assumption on which the original negotiations were based was wrong or that there has been any subsequent change in the time of an examination, the Negotiating Ophthalmic Subcommittee has indicated that it will be prepared to reopen discussions with the Ministry on the terms of service. It welcomes the Ministry's proposal for it considers that the high standard of professional work existing before the appointed day is being maintained under the Supplementary Service, and it hopes that all ophthalmic practitioners will co-operate to the fullest extent in the inquiry.

CLAIMING FEES FOR SPECIALIST ATTENTION

When a general practitioner who is also on a hospital staff as a specialist gives specialist attention to a patient on his NHS list in private pay-bed accommodation of a hospital or in a registered nursing home, he should submit particulars to the local executive council on Form E C 33 before claiming payment from the patient. The practitioner may obtain this form from the local executive council.

DENTISTS' EARNINGS LIMITED

The Minister of Health has made regulations which come into operation on Feb 1 by which dentists' earnings in excess of £4,800 a year are reduced by half. The Ministry of Health states that some 20% of dentists in the Service are at present earning at the rate of £4,800 gross a year or over. The Minister understands that the dental organizations agree with him that excessive earnings should be checked, but that they consider further investigation should precede action, he thinks that the situation calls for immediate action.

THE ASSOCIATION AND PRIVATE PRACTICE

A meeting of what has hitherto been known as the General Practice Committee of the Association was held at Headquarters on Dec 22. Dr S Wand, who has been elected chairman of the General Medical Services Committee, which deals with NHS matters as affecting general practitioners was enabled on that account to continue his chairmanship of the General Practice Committee which he had held for nine years. He was warmly thanked for his services, and the Committee elected to the chair Dr I D Grant, of Glasgow. It was also decided, subject to the approval of the Council, to rename the committee the Private Practice Committee.

It was reported that, following an instruction at the last meeting the Assistant Secretary had met representatives of the Life Offices Association and had discussed the question of a standard fee for supplementary reports. While no fee will be payable for further information in consequence of omissions from the original report or for the elucidation of obscure statements any supplementary information required will be the subject of a fee normally not less than 10/6d.

Correspondence was read on the question of recognizing the Association as the representative body to discuss with the National Coal Board the salaries and conditions of service of its medical officers. The Board is prepared to give an undertaking that as a general principle it will consult the Association on these matters and will be prepared to receive at any time representations on salaries and conditions of service. The range of salaries of the deputy and divisional medical officers was mentioned to the Committee, and it was agreed that there should be a conference with the Industrial Health Committee with a view to considering, within the framework of the Spens Report, the remuneration of the service as a whole.

The question of doctors' signs on motor-cars again came forward. It was the view of London members that the great increase of "yellow band" areas in London made it increasingly difficult for doctors to park anywhere. Three London members of the Committee were asked to go into the detail of various points raised concerning the issue of badges and the like. While it was fully recognized that the authorities could not distinguish in any general way between doctors and other members of the public, the police might well be instructed to use their discretion where a doctor's car was involved.

Some discussion took place on fees for examination of persons alleged to be "drunk in charge." It was stated that in London a fee of three guineas for a night call (from 9 p.m.) and two guineas in the day-time had been secured—at all events in certain police districts. The minimum fees are two guineas and one guinea respectively, but in London apparently the minimum has not followed the usual tendency to become the maximum.

It was reported that the contracts of certain police surgeons had been terminated on the ground that they had not joined the National Health Service. Representations by the Association to senior officials of the Home Office and Scotland Yard had been received sympathetically and an assurance had now been given that no practitioner would be debarred on these grounds from having his name included in the lists of available doctors maintained at police stations in the metropolitan area. In future the list of police surgeons on whom the police can call will be open to any practitioner whether or not he has joined the Service.

A question arose, following a case in Essex, whether a practitioner who undertook one session a week for the county council was holding an office of profit which disqualified him from membership of the Health Subcommittee. One member of the Private Practice Committee said that he was carrying out vaccination and immunization for the London County Council, but nevertheless he proposed to be a candidate for the LCC at the next election. He held that he was not "holding an office of profit" but was being paid a fee for doing a particular job. It was stated that no disqualification attached to a practitioner who undertook vaccination and immunization for his local authority, but that there was some dubiety about a sessional appointment of a clinical character, and the legal aspects of this matter were being further pursued. It is not the National Health Service Act which governs this situation, but the Local Government Act, 1933 (Sections 59 and 94).

The Committee, on a reference from the Council, considered that a Section of General Practice, with which forensic medicine and medical jurisprudence might be combined, would be a very useful feature of the Annual Meeting, and referred it to the Arrangements Committee with a view to the Annual Meeting of 1950.

The Ship Surgeons Subcommittee presented certain proposed amendments of the terms of service suggested by the Shipping Federation for ship surgeons. The desire has been to protect the interests of those surgeons working in ships carrying few passengers and where there is consequently little opportunity of earning private fees. Certain recommendations have been formulated and it is proposed to seek a meeting with the Shipping Federation.

HEARD AT HEADQUARTERS

All At Sea

A problem which has its amusing as well as its important side has been engaging the Ship Surgeons Subcommittee of the Association—namely, whether a man on board ship is or is not a National Health Service patient, and, if he is, to what executive council area he belongs. Does the National Health Service Act extend to territorial waters? Does Mr. Bevan rule the waves? The discussion on this point got very involved, and it was even suggested that a man might be a Service patient as long as his ship was tied to the jetty, but as soon as she slipped her moorings he would be, so to speak, an orphan of the storm. Incidentally, the same sort of problem has just arisen in connexion with patent law. The question is being raised whether, if an invention is stolen and worked only on board ship, and never landed, the patent can be said to be infringed. It is being proposed to amend the Patent Law by declaring that a British ship, wherever it is, is part of British territory. On the matter of the National Health Service legal opinion is to be sought. For the present, as one member put it the sea appears to be "No man's land."

Booking the Fee

Overheard at the Hunterian Society. A surgeon had carried out a successful operation on a farmer, who wanted to know what he owed. He was told fifty guineas, whereupon he pulled out from under his pillow a packet of notes and began counting out fifty-two ten. "Don't trouble to do that," said the surgeon: "write me a cheque." "Ah, but," said the farmer, "you are booked as ten loads of manure."

Names

What should one call a person who goes to a marriage guidance centre for advice—a patient, a client, a case, a suppliant, a seeker, an applicant? *Marriage Guidance*, the monthly bulletin of the National Marriage Guidance Council, has recently put the question to its readers. One attractive suggestion is the Esperanto word *feliconito*, which means "will-be-happy-one." Medical men must also be searching their minds for some appropriate term, distinctive yet not too narrow in its scope, to describe both the man with appendicitis and the one who comes only every two years to get a certificate for glasses. Civil Servants are said to be speaking of "National Health Service units," but the doctor, who is perhaps in closer touch with these ciphers, might be embarrassed to call from his desk, "Next N.H.S. unit, please." Probably we shall continue to use the traditional word "patient" and all that it implies of suffering, even though what people suffer from changes with every statutory regulation. Psychiatrists had better find quickly a diagnostic label for the man who demands a wig to hide his shame.

One Fee for Two Surgeons

When a surgeon operates on a patient who has been admitted to a hospital pay-bed the regulations provide that the total medical fees paid shall not exceed 75 guineas. If the surgeon performs a major operation he receives 50 guineas, but if two surgeons work together on the case they cannot both receive this fee, since the amount paid by the patient would then exceed the maximum. We hear of a surgeon who with his colleague performed a perineo-abdominal operation for carcinoma of the

rectum. He asked the senior administrative medical officer of his region what fee he could charge, saying that this was a double operation carried out at one sitting by two surgeons, two assistants, and an anaesthetist. He was told that had the operation taken place in two stages on separate occasions it would have counted as two operations, but when done at one sitting, whether by two surgeons or not, it is one operation, and the fee must be shared by all concerned. It seems unfortunate that a method of remuneration should be so devised as to penalize a surgeon who very properly works in collaboration with a colleague in a case such as this.

Accountancy Services

The agency work formerly undertaken by the British Medical Bureau is now one of the services performed by the B.M.A. Medical Practices Advisory Bureau, but the B.M.A. cannot undertake accountancy work for individual members. Private accountants will continue to do this, and inquiries should be addressed either to Mr. C. W. Rippen, Tavistock House South Tavistock Square, London, W.C.1, or to Mr. J. Charnock 33, Cross Street, Manchester, 2. The British Medical Bureau was started just over 20 years ago, superseding the Scholastic Clerical, and Medical Association, Ltd., which was founded in 1880. The new Medical Practices Advisory Bureau will have offices at first in London, Edinburgh, and Manchester; other places are also being considered.

Questions Answered

We publish here the answers to a selection of questions that seem to be of general interest.

Maternity Benefits

Q.—Is a woman whose husband has been paying contributions under the National Insurance Act, 1946, only since July 5 eligible for maternity benefits for a confinement which is due early in January?

A.—If the baby is born after Jan. 1, when 26 qualifying contributions will have been paid by the husband, a maternity grant of £4 will be paid. In addition, an attendance allowance of £1 a week for a period of four weeks following the confinement is payable. The attendance allowance will be reduced for any week of this period during which the woman is gainfully occupied. The woman is not eligible for a maternity allowance, because 45 contributions must have been paid before the benefit of maternity allowance comes into force.

Private Certificates

Q.—My patients tell me that instead of paying me a shilling for a certificate for their private sick-club they can get a copy of my N.H.S. certificate from the Labour Exchange. Can the Labour Exchange reproduce my certificate?

A.—No. The patient must obtain it from his doctor, but particulars for a certificate for a friendly society may be obtained from the local office of the Ministry of National Insurance.

Superannuation

Q.—When I entered the Service on July 5 I was 67 years of age. I find that deductions are being made from my remuneration for superannuation. Surely this is incorrect?

A.—No deduction should be made from the remuneration of any practitioner who was over 65 years of age on the appointed day, and if the matter is taken up with the executive council it can be speedily adjusted and any deducted moneys returned.

Special Leave for Congress

Q.—As a part-time specialist can I obtain special leave to attend a national congress in my speciality?

A.—Yes. The interim contracts make provision for special study leave, without loss of remuneration, where approved by a regional hospital board. In the permanent contracts the Executive Committee of the Central Consultants and Specialists Committee has recommended that subsistence and travelling be paid in addition, as suggested in the Spens Report.

Compensation and Income Tax

Q.—We are told that the compensation depended on the amount taken during the two years previous to July 5, 1948. I hear from my accountant that he has had my compensation passed, with the income-tax people signing it, on my income-tax returns for these two years, but he tells me that if I wish to start my income-tax year afresh as from July 5 it might influence my compensation payment. I am severely hit by the N.H.S., and I expect my income will have dropped to half of what it was by the end of the first twelve months, and will probably go on dropping.

A.—Compensation is calculated from the gross receipts of the practice during the last two accounting years completed

before July 5. The assessment of the "annual loss" may be said therefore to represent the amount on which the purchase price would have been based if the practice had been sold on or about the appointed day. The effect of the introduction of the N.H.S. on the income of the practice, or a change in the method of computing tax, does not affect the assessment.

Prescribing for Private Patients

Q.—I am not in the National Health Service, but I am in partnership with two colleagues who are. We are all general practitioners. Can I get one of my partners to prescribe on Form E.C.10 for my private patients, so that they do not have to pay for their medicines?

A.—No. The regulations forbid prescribing in this way.

MEDICAL WAR RELIEF FUND
ANNUAL REPORT 1947-8

1. This report covers the period of twelve months from Sept. 1, 1947, to Aug. 31, 1948. Appended to the report is the audited statement of accounts for the same period.

2. In the third year after the war the need for the existence of this fund is still very apparent. One letter received during the year from a young widow reads: "I first had word of my husband being missing believed killed, then a year later missing believed prisoner-of-war, then a year later presumed to have died of wounds while in enemy hands. Since then life has been one long struggle with three young children to maintain and educate." The Government pension for this young widow and three children is £228 per annum, and she goes on to add: "I dislike letting anyone know the plight I am in, but is there any way of getting help?" Such appeals, so long after the end of hostilities, provide full justification for continuing the activities of the fund.

3. During the year 42 applicants were granted assistance amounting to £6,663. Twenty of these applicants had previously received help. As in earlier years, the purposes for which most of the grants were voted were: first, to assist practitioners to re-establish themselves in civil practice (18 applicants); secondly, to assist widows with the education of children (15 applicants).

4. In those cases where a grant is to be paid over a period of time, or is for the purpose of school fees, the grant is administered through the office of the Royal Medical Benevolent Fund, and 12 grants amounting to £1,696 were voted in this manner.

5. From time to time the Distribution Subcommittee receives reports on the progress of cases helped in previous years, and

the circumstances are then reviewed and fresh grants are voted if the need is shown. Every effort has been made to keep in touch with all the cases where children are concerned and to ensure that the education is progressing.

6. The following is an extract from a letter written by a beneficiary of the fund during the year: "I really find it rather difficult to express the deep gratitude I feel for the more than generous gift voted to me. The second gift came as a total surprise. Never before in my life have I received such a welcome gift. It makes all the difference between pinching and scraping and knowing that, at last I have a little something behind me." Another widow writes: "I just don't know how to thank the Committee for the wonderful kindness and generosity. It is impossible to describe to you what a relief your gift has brought to me and what a burden it has lifted from my shoulders." The Committee of the Fund, acting as the Trustees on behalf of all the subscribers, quotes these letters in order to convey to the subscribers the heartfelt gratitude of the recipients and as a proof that the subscribers' generosity was not misplaced.

7. Once again the Committee wishes to record its indebtedness to the Royal Medical Benevolent Fund for its continued co-operation, and its appreciation of the valuable services rendered by Mr. E. C. Pennefather as Honorary Secretary of the Distribution Subcommittee.

8. The statement of accounts shows that the fund still has a substantial unspent balance, and, as has already been announced, the Committee thinks it unnecessary to seek further contributions at the present time.

H. GUY DAIN. *Chairman.*

Chartered Accountants.
Honorary Auditors.

A solution would be to appoint a small number of whole-time obstetricians from the general practitioners in each area. They would be chosen not only for their experience but also for their love of obstetrics and would eschew all further general practice. They would undertake any domiciliary obstetrics referred to them by the general practitioners, who would still be permitted to look after their own cases should they so desire. It would then be possible rapidly to improve the standard of obstetrics, to the benefit of patients and of hospital gynaecological departments alike.—I am, etc.,

Ewell, Surrey.

PAUL WINGATE.

The Independence Fund

SIR,—May I say how thoroughly I agree with the sentiments expressed in Dr. R. C. McIntosh's letter (*Supplement*, Jan. 1, p. 8)? Surely we have all learnt by now that the only way with dictators is to treat them rough, for it is the only thing they understand. A small minority who are doing very well out of the Health Service—so far—will of course protest against a wholesale resignation from what is becoming a racket—and a tragedy for some.

In another letter Dr. V. Weston (p. 8) has truly hit the nail on the head. It is astonishing that only just over 5,000 of our profession were prepared to back their fancy.

I am beginning to have some sympathy for our Council. Even some of us who have no interest in the Health Service thought the Independence Fund a pressing duty to support.—I am, etc.,

London, N W 3.

H. V. DEAKIN.

** As we stated at the foot of Dr. Weston's letter, 5,325 medical men and women contributed to the Independence Fund.—ED., *B.M.J.*

Freedom of the Profession

SIR,—In the *Supplement* of Dec. 4, 1948 (p. 203), in the report of the conference of Local Medical Committees Dr. Guy Dain is reported to have made the following statement: "There is a new organization called the Fellowship for Freedom in Medicine, and if they can assist us in any way to help maintain the freedom we have got we shall be only too glad of their help." But what is this freedom that they have got? Dr. Dain claims to have attained clinical freedom, freedom of speech, freedom of choice both ways for patients and doctors, freedom to do private as well as State work, freedom to regulate our lists—we need not take more than we like, and we can practise where we like if the area has not been declared an over-doctored one.

Let us consider these freedoms one by one, these freedoms that Dr. Dain claims to have "attained" (can he mean "retained"?).

(a) *Clinical Freedom*.—Was it ever seriously suggested by anybody that Mr. Bevan or one of his Civil Servants would wield the scalpel or use the stethoscope?

(b) *Freedom of Speech*.—Do we have to regard it as an achievement in this country that professional men are still allowed freedom of speech?

(c) *Freedom of Choice*.—Was it ever threatened that patients would be compelled to attend doctors they dislike or that doctors should see patients to whom they objected?

(d) *Freedom to do State and Private Practice*.—What is this freedom worth when, thanks to the Act, there are no private patients left for 93% of the general practitioners? As for the specialists, no one ever dreamt of precluding them from being consulted by private patients.

(e) *Freedom to Regulate our Lists*.—Does this mean any more than that we are not obliged to take on more patients than we are capable of looking after?

(f) *Freedom to Practise Where We Like if it is not an Over-doctored Area*.—This freedom is illusory. Mr. Bevan promised that if a doctor were asked for as a partner or a successor the consent of the relevant committee would be automatic. His pledge has not been fulfilled. Nor so far has any list of over-doctored areas been published. (What is an over-doctored area?)

So much for the vaunted freedoms. But Dr. Dain speaks with two voices in the same speech. His list of freedoms is far less formidable than his list of servitudes. He speaks of doctors' requests for closed areas against other doctors (negative direction) because of financial stringency. He talks of the lack

of medical manpower and of work that is overwhelming us. He warns us that the forthcoming winter may cause a complete breakdown. He foresees the pressure that will be exerted to secure that those suffering hardships or serious diminution of income should have a special claim from the Special Inducement Fund. And, to crown all, he says:

"We are now in the position that we are no longer handicapped by the fear that we may lose our compensation, and if we do not get satisfaction quickly it will not be beyond the bounds of possibility to withdraw our services, not entirely because we are not getting enough money, but because under the conditions obtaining we cannot properly 'deliver the goods.'"

Are these the accents of a victor in a struggle for liberty? Surely these frank statements by Dr. Dain are entirely at variance with his claim that we have definitely attained a position of freedom. The truth is that the very opposite of freedom has been attained in fact—a state of servitude and indignity never before thrust on any profession in this country.—I am, etc.,

London, W.1.

GEORGE ROSSDALE.

Ophthalmic Service

SIR,—I have received a communication from the chairman of the Ophthalmic Subcommittee of the Negotiating Committee that they have asked the Negotiating Committee to seek a further meeting with the Ministry with a view to modifying the conditions of the Supplementary Service. The reason for doing this is that there is a minority of practitioners whose earnings have been such that it must be concluded they are not giving the half-hour for a full ophthalmological examination which the committee had promised they should do.

I append my reply to the chairman, which I shall be grateful if you will publish, as I think it must be of interest to all medical men at the moment when the question of remuneration is causing so much dissatisfaction, and I think that most will agree with my views.

"I am in receipt of your letter re the remuneration of specialists in the Supplementary Ophthalmic Service. I feel sure that the object of the Negotiating Committee in seeking a further meeting with the Ministry in order to modify the conditions of the Service is actuated by their interest in the welfare of the patient and not because they feel that some of their colleagues are making too large an income. I would therefore ask that you would take the opportunity of suggesting to the Ministry that the number of patients attending the out-patient departments at hospitals should be limited in a similar manner.

"The out-patients' session is supposed to last 2½ hours, but I find that my own invariably last four hours, and during this period I probably see 30 or 40 patients. I am quite sure that if the regional board paid a sum of, say, £1 1s. per patient instead of £4 4s. a session they would probably decide that I am seeing far too many patients in a session, but as there is a fixed sum of £4 4s. this large number of patients who are seen in too short a time causes no disquietude. I would suggest, therefore, that only five new patients were seen in any one session of 2½ hours or ten old patients, because patients attending the out-patients are usually referred cases and many of them pathological, and therefore requiring quite as long a time as do the ordinary simple refraction cases which are seen under the Supplementary Scheme.

"At the Ophthalmological Services Committee of Surrey, when it was suggested that as the refraction fee for a patient for ophthalmic medical practitioners had been cut from £1 11s. 6d. to 12s. 6d. it seemed a little strange that the optician who measured the patient for glasses should continue to receive £1 5s. 6d. for this service, the optician members of the committee showed no desire to seek an interview with the Minister with a view to modifying this fee."

—I am, etc.,

Camberley, Surrey

LESLIE HARTLEY.

Long-term Policy Required

SIR,—There is no doubt, as your correspondents have so often maintained, that no doctor can do a really good and conscientious job with a list of more than 2,000 to 2,500 patients, and that something should be done soon to limit the lists and raise the capitation fee. The latter is quite inadequate as a measure of services given and bears no real relationship to the present-day cost of living.

It seems to me that up to the time of the inception of the Health Service there were two distinct types of medical practice, but that since its inception the distinction is rapidly disappearing, to the lasting detriment of patient and doctor alike. The

first type of general practice was and is a product of industrialized and urban areas. In this type weight of numbers force upon the doctor a course of action in sheer self-defence which at first he resents but later comes to accept as normal practice for want of the ability to do anything different. The second type of medical practice is that in which the patient is given an adequate examination and is properly instructed and prescribed for. It is now rapidly disappearing under the weight of extra work following the start of the new Health Service.

Up to the time of inception of the Health Service the first type of practice provided a reasonable income with some hope of retirement; but the second type, while it provided an adequate living, held out little hope of retirement. In the first instance it is impossible to blame the doctor for the state of affairs. Circumstances precluded anything else. But however necessary this state of affairs may have been before, it is wholly indefensible and something that should not be tolerated for a moment longer than is absolutely necessary in any health service which has the interests of patient and doctor at heart. As a permanent state of affairs it is quite undesirable. As a short-term solution the only remedy would appear to be smaller lists and higher capitation fee. The high capitation fee is nothing less than the just due of those who take on the heavy responsibility and exacting demands, both physical and mental, coupled with unearthly hours of work. But smaller lists of the order suggested mean probably almost doubling the doctors to pay and may not be an economic possibility. In view of the fact that the Health Service is likely to cost the nation many millions more than its sponsors have anticipated. I suggest that a long-term policy is urgently required, one which will raise the resistance of the people to disease and so ultimately lighten the present well-nigh intolerable burden on the medical profession. It is a policy not so much for the medical profession as for the Government, but who better than the medical profession to keep the matter before the notice of the public and of the Government?

Surely the time has now come to determine for all time the role played in the lowering of resistance to disease and in the production of ill-health by present practices in the treatment of the soil and of food, by the educational system, and by the economic system, and to press for reforms which will improve the health of the people. For it seems to me, Sir, that unless and until these factors are taken into account and tackled fully and conscientiously we shall continue to see an increase of ill-health among the people and the vexed question of the Health Service will continue to vex.—I am, etc.,

Troon, Ayrshire.

HUGH L. MACKINTOSH.

Salaries of Opticians and G.P.s

SIR,—I have the greatest admiration for that hard-working friend of us all, the general practitioner. I know that Dr. J. W. Nicholas (*Supplement*, Dec. 18, 1948, p. 230) is right in his contention that a twelve-hour day is often his lot. Nevertheless, I must refute the suggestion that the average ophthalmic optician works for only six hours per day. This may be the bare time allowed for the examination and measurement for spectacles of new patients, but it cannot represent the full extent of his activities per diem. He may, in fact, have to see that patient at least three times.

It must be remembered that in addition patients already examined will be returning for their glasses, which will have to be fitted and adjusted. Others will be returning for adjustments (for which no charge is made) and repairs, which he will effect on the premises where possible. In addition he will have to write up his records and his orders to the manufacturers and supervise his workshop if he has one. He will have to check the measurements of the frames and power of the lenses returned to him. Small wonder that many opticians complain that the book work and form-filling, reports to doctors, etc., have to be done at home and that the full day amounts to ten to twelve hours. Much can be done in this last respect by a competent secretary-receptionist (whose duties are not only writing letters), who is absolutely essential to make appointments, answer the telephone, explain delays to patients, help them with their forms, etc.

The optician's dispensing fee was calculated on the average remuneration he obtained under the old National Health Insurance Act and is approximately the same and far less than the

fees obtainable for private work. Far from being overpaid, many at the moment are complaining that they are worse off, and many, in fact, are overdrawn at the bank.

Mr. D. Stenhouse Stewart (p. 231) writes of 16 refractions per day. This is, of course, quite possible in the case of a firm where two or more qualified opticians are working, but the actual overheads will be increased accordingly. He talks of £150 per month amply meeting establishment expenses. Has he any idea of present-day salaries? I can assure him that this figure will hardly cover the salary of a senior qualified optician plus a receptionist, or a mechanic, let alone rent, rates, lighting, telephone, workshop expenses, etc., which are generally, I submit, considerably higher than those of the general practitioner.

If the general practitioner is underpaid, this should be rectified. Nobody would be more pleased than my profession to see this happen, but the way to do it is surely not to decry the optician, who is doing a job of work conscientiously and well, but to press for the revision of the medical remuneration on the merits of its own case.

Finally, may I point out that my profession feels strongly that adequate time must be given to each patient requiring eye examination. The Council of the Association of Optical Practitioners, following the lead of the British Optical Association, has recently passed the following resolution:

"That if it is shown that a member of the Association of Optical Practitioners has given insufficient time or inadequate service to his patients, he will render himself liable to disciplinary action under the A.O.P. Articles of Association."

—I am, etc.,

G. H. GILES,
Hon. Secretary, Association of Optical Practitioners.

Civil Service Medical Officers

SIR.—A good deal of correspondence has been published in recent issues of the *Supplement* under the pen name of "Civil Service M.O." and "Another Civil Service M.O." As Chairman of the Institution of Professional Civil Servants' Medical Panel I consider it opportune to enumerate some of the objects of this Institution, which is the duly recognized and responsible negotiating body for Civil Service medical officers. It is concerned with:

- (1) The maintenance and improvement of the position and status of its members.
- (2) The protection, assertion and enforcement, or the assistance therein of the status, position, rights, remedies, and interests of such public servants.
- (3) The advancement of efficiency in the public service, the promotion, teaching, and extension of professional science, knowledge, and practice, and the interchange of views thereon.
- (4) All these objectives may be promoted or effected by the Institution either alone or in combination with other persons or bodies.

In relation to medical officers, the Spens Reports are in the nature of a charter. For the first time an independent body has set out what they consider to be the proper level of remuneration for the profession, and this has been accepted in principle. The Civil Service medical officer is not seeking merely remunerative parity with the administration but remuneration which has its proper affinity to that obtaining for the medical profession generally. It must include adequate recognition of the long duration of a medical education; the late entry, with consequent effect on pension entitlement; the fact that the majority of medical practitioners are recruited as experienced practitioners of proved capacity; and the need for bringing the salaries of the Civil Service medical officers in line with those of the medical profession. Moreover, the remuneration should bear a close relationship to qualification, experience, and nature of duties of Civil Service medical officers.

The Institution of Professional Civil Servants has made it quite clear to the Treasury that in their view members of the medical profession in the Civil Service should be paid in accordance with the levels of remuneration contained in the Spens Reports. The Medical Panel of the Institution has for some months now been at work preparing an appropriate claim based on the Spens Reports. The claim is now in its final stages of preparation, and we anticipate submitting it to the Treasury in the immediate future.

As was said in the letter of the *Supplement* of Nov. 6, 1948 (p. 166), there are in the Civil Service many medical officers of

consultant and specialist status, and this is an aspect of the question which will be reflected in the pay scheme that will be submitted. The Institution has no doubt that the British Medical Association will fully support the claim when it is tabled.

In conclusion, if the writers of the above-mentioned letters have not already done so, it is strongly recommended that they should join the Institution, where matters pertaining to medical ethics, duties, and remuneration, to mention a few, are fully discussed and negotiated in the interest of all Civil Service medical officers.—I am, etc.,

CHAIRMAN,
Medical Panel,
Institution of Professional Civil Servants.

Master Minds

SIR,—With reference to the annotation headed "Master Minds" (*Journal*, Jan. 1, p. 23), I am instructed by my chairman to ask you to be good enough to publish a letter received by my committee from Mr. Messer, the contents of which are as follows:

"I am in receipt of your letter with copy of paper enclosed, which I am returning herewith.

"This report has already been brought to my notice and I need hardly say that I read it with very great distress. It is an instance where tearing a passage out of the context makes a very great difference. All I was trying to do was to explain the difficulties under which the general practitioners work and expressing the hope that the establishment of health centres would give them better opportunities. I have never, at any time, criticized the work of the general practitioner, as I realize the essential part they play in the Service.

"I have, from time to time, referred to the lack of organization of the general practitioner services, but this, of course, is a matter generally recognized.

"If anything I have said has given rise to a feeling that I have in any way reflected on the professional integrity of the general practitioner, I would be most anxious to correct it and I sincerely hope that the cordial relations which have existed between the profession and myself for so many years will continue."

Mr. Messer has given permission for his comments to be published.—I am, etc.,

D. F. HUTCHINSON,
Secretary,
Middlesex Local Medical Committee.

London, W.C.1

POINTS FROM LETTERS

Locums

Dr. SHACKLETON BAILEY (Eye, Suffolk) writes: . . . I suggest that executive councils accept some responsibility for what goes on in their areas when doctors are ill or on holiday. It would be a great convenience if they had a small panel of locumtenents at their disposal who could come to the rescue in emergency and who would be available to the doctors in the area concerned for holiday purposes. Doctors would of course book their holidays well in advance, and late applicants might have to take their holidays when the locums were available rather than just when they liked. But I am sure everyone concerned would be glad to make occasional sacrifices of this sort for the security of a good locum who was responsible to the executive council. It might be a little more costly, but a good locum is worth paying for. The executive councils would recruit their panel of locums mainly from young qualified men who desired to practise in a particular area. A man who had served an executive council well in the capacity of a locum would have the assurance that he would be a strong candidate for any vacancy in general practice occurring in the area. The doctors in the area would know his capabilities and he would get a fair idea of what practice there was like before settling down. . . .

Outstanding N.H.I. Fees

Dr. M. LETHBRIDGE FARMER (Portishead, Somerset) writes: . . . May I ask what has happened to the outstanding balances for 1947-8 of panel fees, mileage, and dispensing fees due under the N.H.I.? These represent in part remuneration for work done and in part actual out-of-pocket disbursements. The contract of service under which they were earned or incurred terminated on July 5, yet the clerk of the insurance committee concerned with those due to me tells me that the necessary allocation of funds to meet them has not as yet (Dec 16) been made. In view of the vast excess of expenditure over estimates for the new Service, are we to write these amounts off as a bad debt on the part of the Ministry? . . .

* A note on these payments appeared in the *Supplement* of Jan. 1 (p. 3).—Ed., B.M.J.

H.M. Forces Appointments

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

War Substantive Captain F. J. Pounds has relinquished her commission and has been granted the honorary rank of Major.

War Substantive Captains J. W. Paul and N. M. Dwyer have relinquished their commissions and have been granted the honorary rank of Captain.

War Substantive Captain L. Blackburn has relinquished her commission and has been granted the honorary rank of Captain. (Submitted for the notification in a *Supplement* to the *London Gazette* dated March 8, 1946.)

Association Notices

FULL-TIME NON-PROFESSORIAL MEDICAL TEACHERS', LABORATORY AND RESEARCH WORKERS' GROUP

A meeting of the Group of Full-time Non-Professorial Medical Teachers, Laboratory and Research Workers will be held E.M.A. House on Thursday, Jan. 27, 1949, at 5 p.m. The main business will be to receive the report of the Group Committee, and an item of particular importance will be a discussion on the Spens Report and its application to specialist holding university posts, and those who are not in contract with boards of governors of teaching hospitals or regional hospital boards. The Group Committee extends a cordial invitation to all non-members of the Group who may be interested.

Diary of Central Meetings

JANUARY

12 Wed. Council, 10 a.m.

Branch and Division Meetings to be Held

ROCHESTER, CHATHAM, AND GILLINGHAM DIVISION.—At All Saints Hospital, Chatham, Thursday, Jan. 13, 8.30 p.m. Clinical meeting. All medical practitioners in the area of the Division are invited.

TUNBRIDGE WELLS DIVISION.—At Kent and Sussex Hospital Wednesday, Jan. 12, 8.15 p.m. Sir Leonard Parsons: "Comm. Oversights in the Acute Diseases of Children."

WESTMINSTER AND HOLBORN DIVISION.—Joint meeting with Chels and Fulham and Kensington and Hammersmith Divisions, at Postgraduate Medical School of the Royal Cancer Hospital, 24, Onslie Gardens, Fulham, S.W., Wednesday, Jan. 12, 8.30 p.m. Mr. C. Shattock: "Cancer of the Breast." Open to all medical practitioners in the area of the Divisions.

WINCHESTER DIVISION.—At County Hospital, Winchester, Sunday, Jan. 9, 11 a.m. Meeting. Agenda: National Health Service Remuneration. Consideration of the following Resolutions: (i) *Frc Ashton-under-Lyne Division*: "This Division demands a Special Representative Meeting for the sole purpose of deciding up immediate action to raise the capitation fee to an equitable basis; (ii) *From Torquay Division*: "That unless the Spens Report, plus an adequate betterment factor, is implemented by March 31, 1949, mass resignation of all members of the B.M.A. in the general practitioner service should be called for by the Council of the Association and to this end a Special Representative Meeting should be called for not later than the first week in February." (iii) *From Rochdale Division*: "This meeting views with great dissatisfaction the apathy of the Central Body in respect of the present unsatisfactory capitation fee, and is strongly of the opinion that a Special Representative Meeting should be called not later than Feb. 15, 1949, in order that the Negotiating Committee may be given new and urgent instructions for an approach to the Minister regarding the remuneration of all sections of the profession." Consideration of Birkenhead and Wirral Division: "That this Division recommends the formation of a trades union within the framework of the B.M.A., this being in our opinion, the best way of safeguarding our interests." Organization of the B.M.A.: (i) Report of the Division Representatives on the B.M.A. Organization Committee Meeting (ii) Consideration of draft of new memorandum based on Reports received from Divisions.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar
Non-County Borough Councils.—Dartford, Radcliffe (limits to future appointments), Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-l-
Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

LONDON SATURDAY JANUARY 15 1949

PULHEEMS

A NEW SYSTEM OF MEDICAL CLASSIFICATION

BY

ROY T. FLETCHER, M.B.E., M.D.

Major, R.A.M.C.

(From the Hygiene Directorate, War Office)

The Pulheems system of medical classification was officially adopted by the Army on April 1, 1948. It has also been accepted by the Royal Navy, the Royal Air Force, and the Ministry of Labour and National Service, whose Medical Boards took it into use on June 1, 1948.

The object of this paper is to introduce Pulheems to the profession and to stimulate interest in this new system of classification so that doctors called upon to examine recruits or to act as medical officers will be familiar with the principles involved. The Pulheems system commands attention because it provides us for the first time with a method of expressing on paper in a concise and easily recognizable form the physical and mental capacities of an individual. I consider that when it becomes generally known it will be accepted by the profession and applied on a wide basis. Certainly it goes a long way towards unifying and rationalizing our standards and towards improving our "clinical" appreciation of physical and mental fitness. While we are still unable to measure physical and mental capacity by purely clinical means, Pulheems is undoubtedly a great advance on methods hitherto employed.

It is hardly surprising that the Forces Medical Services should be responsible for developing a comprehensive system of medical classification, since in the Services organized medicine has been developed to a high level and Service requirements clearly call for some means of assessing accurately the fighting-man's physical and mental capacity. It seems probable that with a National Health Service, and in view of the necessity for the economic employment of our man-power in industry and elsewhere, the Pulheems system of medical classification will meet an essential need. Further, if the physical fitness of our people is to be safeguarded by comprehensive health surveys of the population will have to be undertaken, and in order to derive full benefit from such surveys we must pay due attention not only to clinical states but also to "health" or physical and mental capacity.

Medical Classification in the Past

The need for a system of medical classification in the Army became apparent during the South African War (1899-1902), when for the first time officers and men were examined with respect to their physical fitness for service at home or abroad. It was not until the war of 1914-18 that any further breakdown of these two broad classes was attempted, and following the introduction of the Military Services Act in January, 1916, the scope of medical classification was extended to include all serving officers and men at home and abroad. The system of lettered categories, which later became so familiar, was introduced at that time, and

it was with this system of classification in vogue that we were called upon in 1939 to face the war. During the ensuing years the increasing demands on man-power necessitated successive extension of the medical categories used, and as a result the category system became more and more complicated, while at the same time it failed to meet the new demands placed upon it.

Briefly, the reasons for the failure of the former system of medical categorization are as follows:

The medical categories used (a) did not adequately define a man's physical or mental limitations, and it was therefore not possible to allocate the man to employment in which full use could be made of those capacities which were not in any way impaired, (b) gave no indication of the mental and emotional make-up of the individual, factors which in total warfare are no less important than the physical attributes, and (c) merely indicated restrictions on employability of a very generalized nature, giving no information about the particular disability involved. They therefore provided no guidance on the most suitable type of work for any given soldier with due regard to the nature of his disability. In short, the medical category system was designed to meet the requirements of our traditional Army (and particularly the infantry soldier), which marched on its feet and fought with a rifle. It was not a system designed to cater for the modern mechanized Army engaged in technological conflict.

With the introduction of personnel selection procedure into the Army in 1942, the deficiencies and shortcomings of the medical category system were further revealed and emphasized. The range of employments available in a modern army is extremely wide and varied, and each individual job brings into use different mental and physical functions, which in turn may have to be qualified according to the conditions and environment in which the work has to be performed—e.g., tropical, arctic, front-line action, etc. It will be agreed that to ply a trade under direct shell-fire is totally different from practising the same trade in the safety of a base workshop, and that a man with chronic ear disease who may be perfectly fit to serve in a temperate climate is likely to break down when serving in the Tropics or subtropics. Clearly, minor disabilities which are of little significance to a member of the training staff of a static base installation can represent a serious liability in an active combatant unit.

From the foregoing it is apparent that the lettered system of medical categorization proved very wasteful from the point of view of man-power economy. In order to employ men satisfactorily in the Army the medical authorities must provide a clear-cut specification of the individual's

functional capacities. Only in this way can men be employed to the best advantage, man-power economy be effected, and the individual himself be satisfied.

Progress towards a New System

Had it not been for the crisis of 1939 it is likely that steps would have been taken to improve our system of medical classification to meet the demands of mechanization and the numerous new employments created; but the British Army authorities considered it both undesirable and totally impracticable to introduce a new system once war had started. However, in 1943 the Canadian Army authorities introduced a new system of medical classification which they called "Pulhems," chief credit for which goes to Major-General Brock-Chisholm, then Director-General of the Canadian Army Medical Services. It was he who first suggested that men should be examined in respect of seven subdivisions of bodily and mental function, and as a result a committee was appointed to investigate the possibilities of such a scheme. This committee designed the Pulhems system of medical classification now used by the Canadian Army.

Subsequently the attention of the British Army authorities was drawn to this system and selected groups of Army intakes were examined by that method. The trial, though limited, proved that it was possible to assess the functional capacity of the individual and record the findings in terms which would be easily understood by his employers (and selection officers); but, as already indicated, it was not possible to introduce the system generally at that time. In 1946 an Inter-Services Committee was formed "to devise a system of medical classification which would be suitable for use by the Royal Navy, the Army, and the Royal Air Force." It was agreed that "Pulhems" should form the basis of discussion, and eventually this committee devised the system known as "Pulheems—a system of medical classification for the Fighting Services." It is this system which has been adopted and which I will now proceed to describe.

The Pulheems System of Medical Classification

The Qualities—Under the Pulheems system of medical classification examination of the individual is carried out objectively, with particular reference to seven subdivisions of bodily and mental function, the code letters of which go to make up the word "Pulheems" as follows:

- P—Physical capacity
- U—Upper limbs
- L—Locomotion
- H—Hearing (acuity)
- EE—Eyesight (visual acuity)
- M—Mental capacity
- S—Stability (emotional).

These subdivisions are known as *qualities*.

Visual Acuity (EE).—Under the former systems of medical categorization specified visual standards were laid down and each category was permitted certain of these standards—e.g., A1—V.S.1, 2, or 3; A3—V.S.4; A4—V.S.5 or 6, etc. Such visual standards are still being used by the Canadian Army, hence their use of the single "E." The Royal Navy and the Royal Air Force found that the wide range of vision permissible in some of the categories previously used made accurate employment of men in various technical trades extremely difficult. In the discussions which took place on the subject these two Services insisted that, to meet the requirements of their tradesmen, the new system must specify the precise degree of visual acuity in each eye separately, both without and with the aid of glasses. This requirement was met by introducing a separate "E" for

each eye, subdividing the medical box under each of the "E's" so that the unaided vision could be shown in the upper half of the box and the aided vision in the lower half. The method of recording visual acuity is based on the following standards:

6/6 = 1	6/24 = 5
6/9 = 2	6/36 = 6
6/12 = 3	6/60 = 7
6/18 = 4	Less than 6/60 = 8

Thus, for example, EE is recorded as follows for a man whose uncorrected vision is R=6/12, L=6/18 and whose corrected vision is R=6/6, L=6/9:

E	E
3	4
1	2

the first "E" indicating the visual acuity in the *right* eye and the second "E" that in the *left* eye.

Degrees of Each Quality.—There are eight degrees under each quality, but for reasons which will emerge later not all of these are used in the case of U, L, H, M, and S, as the following table shows:

P	U	L	H	E	E	M	S
1	1	1	1	1	1	—*	—*
2	2	2	2	2	2	2	2
3	3	3	3	3	3	3	3
4	—	—	—	4	4	—	—
5	—	—	—	5	5	—	—
6	—	—	—	6	6	—	6
7	7	7	7	7	7	7	7
8	8	8	8	8	8	8	8

Functional Interpretation of the Degrees of Each Quality

The degrees of each quality, excepting H and EE, refer to functional ability. The degrees of H and EE are related to definite standards of hearing and eyesight, degree 8 under H signifying the man is unfit for any form of military service. Table I shows in detail the functional requirements of the degrees used under each of the qualities other than EE. Under this quality the minimum visual requirement for certain essential duties—e.g., shooting, driving, etc.—is detailed.

Climatic Restriction.—During the 1939–45 war major causes of invaliding to the United Kingdom from overseas theatres were skin, ear, eye diseases, and psychiatric disorders. After treatment in the United Kingdom many of these men recovered sufficiently to become fit even for full combatant duties provided they were retained in a temperate climate. In order to avoid sending such men to climates where they would break down because of disabilities which remain quiescent only in a temperate climate it is essential to indicate the necessity for climatic limitation. Under the Pulheems system degrees 4, 5, 6, and 7 are used for this purpose. In the assessment of the qualities U and L, any pathological condition of the limbs, such as osteomyelitis, will have a general constitutional effect. This also applies to diseases of the ears and eyes—as opposed to hearing (H) and eyesight (EE). It is therefore convenient to confine the specification of climatic restriction so far as the qualities P, U, L, H, and EE are concerned to the assessment of the P quality only, and for this reason degrees 4, 5, and 6 are not used under U, L, and H. With regard to M and S, experience in the last war indicates that men of low intelligence adapt themselves poorly to strange and unfamiliar surroundings. Intelligence once assessed remains a constant factor and is not directly related to the question; for Army purposes,

*With regard to "M" and "S," degree 1 implies functional efficiency "above average," which it was considered extremely difficult to assess; thus degree 2 under these qualities indicates normal or better.

TABLE 1.—*Guide to Pulheems: Functional Interpretation of Degrees of Each Quality*

Degree	P	U	L	H	EE	M	S
1	Fits, after training, for full strain and fatigue on combatant duty. Fit to withstand exposure to all kinds of weather. A front-line fighter in any part of the world	Muscle power above average. Must be able to handle a rifle and do heavy manual work, including digging, pushing, dragging, heaving, lifting, and climbing. All tasks carried out with rapidity and efficiency	Capable of very severe locomotor strain for 5 or 6 days. Can undertake forced marches and fight at the end of such marches. Can run, climb, jump, crawl, swim, and perform all kinds of labour quickly	Very good hearing. Ability to hear sufficiently well to perform any duty	Unaided vision E 3 or 1 B 3 or 1 Able to see to shoot and drive	Ability under Army conditions to learn to perform successfully full combatant duties. Includes those who can be trained as tradesmen and specialists	Emotionally fit to perform Army duties adequately under full combatant conditions in any part of the world
2	Fits for normal work or strain but unable to endure "extreme" degrees for long periods. A front-line fighter in any part of the world	Muscle power average. Able to do all a U.I. man can do but at a slower pace	Same as L1, but pace may be slower	Good hearing. Able to hear sufficiently well to perform any duty	Aided vision E 3 or 1 B 3 or 1 Able to see to shoot and drive	Ability under Army conditions to learn to perform simple labouring duties, including fitness to bear arms in self-defence	Whilst having a history of emotional instability is at present well adjusted and fit to serve in any part of the world in a role which is not primarily a fighting one
3	Fits for ordinary work. Has not the stamina, even after training, to endure the strain and fatigue of full combatant duty. Fit for restricted service in any part of the world	Must be able to use a weapon for defensive purposes and be capable of less severe forms of manual work than U2	Capable of marching 5 miles or further in an emergency. Able to stand for periods of at least 2 hours. Fit for guard duties	Able to hear sufficiently well to perform any duty where moderate impairment of hearing does not disqualify	Aided vision E 3 or 1 B 3 or 1 Able to see to drive but not to shoot	Ability under Army conditions to learn to perform simple labouring duties, including fitness to bear arms in self-defence	Whilst having a history of emotional instability is at present well adjusted and fit to serve in any part of the world in a role which is not primarily a fighting one
4	Fits, after training, for full strain and fatigue of full combatant duty provided he serves in temperate climates only				Aided vision E 3 or 1 B 3 or 1 Able to see for ordinary purposes (not shooting or driving—binocular)		
5	Fits for normal work or strain but unable to endure "extreme" degrees for long periods. Fit for service in temperate climates only				Aided vision E 3 or 1 B 3 or 1 Able to see for ordinary purposes (not shooting or driving—binocular)		
6	Fits for ordinary work. Has not the stamina, even after training, to endure the strain and fatigue of full combatant duty. Fit for restricted service in temperate climates	Capable of sedentary and routine work of a lighter type. Includes personnel unable to bear arms on the front line (e.g., signaller, clerk, etc.). Service in the U.K. but may serve overseas in the base area	Able to walk 2 miles per day at own pace. Can stand for moderate but not prolonged periods. Service in the U.K. but may serve overseas in the base area	Able to hear sufficiently well to perform any duty where marked impairment of hearing does not disqualify. Service in the U.K. but may serve overseas in the base area	Aided vision E 3 or 1 B 3 or 1 Able to see for ordinary purposes (not shooting or driving—binocular)		Whilst having a history of emotional instability is sufficiently well adjusted to serve in a role which is not primarily a fighting one
7	Capable of performing useful Army duties within limits of his disabilities. Not likely to break down if included in time for regular meals and rest. Service in U.K. only	Capable of sedentary and routine work of a lighter type. Includes personnel unable to bear arms on the front line (e.g., signaller, clerk, etc.). Service in the U.K. but may serve overseas in the base area	Able to walk 2 miles per day at own pace. Can stand for moderate but not prolonged periods. Service in the U.K. but may serve overseas in the base area	Able to hear sufficiently well to perform any duty where marked impairment of hearing does not disqualify. Service in the U.K. but may serve overseas in the base area	The E.B. boxes bear no relation to the degree of the disability. E.B. boxes are used in the U.K. only. Being a minimum record of vision unaided and aided	Because of low mental capacity is unfit to bear arms, but is capable of simple labouring duties under supervision, including a minimum of responsibilities. Service in U.K. only	Emotionally fit to perform Army duties adequately under living conditions favourable to the individual in the U.K.
8							
Factors to be considered	Ages, build, strength, and stamina-guts	Strength, range of movement, and general efficiency of upper arm, shoulder, ankle, and back	Strength, range of movement, and efficiency of feet, legs, pelvic girdle, and lower back	Auditory acuity	Visual acuity	Mental capacity	Emotional stability

UNFIT FOR ANY FORM OF MILITARY SERVICE

however, men whose mental capacity is incompatible with employment in any part of the world can be employed only at home (i.e., degree 7), hence degrees 4, 5, and 6 are not used under M. The S quality has a material bearing on climatic restriction, but it is considered that a man who requires restriction to service in a temperate climate because of emotional instability is unlikely to be employable in a combatant role; therefore under S degrees 6 and 7 only are used. Men with psychosomatic disorders—e.g., effort syndrome, functional dyspepsia, etc.—may require a lower assessment under P as well as S. Finally, if an individual has a low assessment under one of the qualities other than P, it does *not* follow that the same assessment must be made under P—e.g., a man who is assessed L7 but is physically fit to be assessed P3 should be classified P3 and not P7. Lowering of the P assessment to 7 in such a case would impose unnecessary restriction on employment. Any individual, however, assessed degree 7 under P, M, or S can serve only in the United Kingdom.

From the foregoing it will be seen that climatic restriction is decided by the assessment of the individual under the qualities P and S, and to a lesser extent under the quality M. Employment within the various areas in the theatre—i.e., forward, lines of communication, or base—is dependent thereafter on the complete assessment.

Temporary Assessment.—(a) "R" Assessments:—Where an individual is suffering from a condition which is remediable by surgical operation or other means (e.g., hernia, poor physique) he is classified according to his present capacities (but not lower than 7) and the letter R is inserted immediately after the degree of P, U, L, or S affected, the period of temporary restriction from full duty of the assessment being stated—e.g., P3R for three months. Such an individual remains on duty, and at the conclusion of medical treatment is reassessed.

(b) "O" Assessments:—When an individual is off duty and under medical care he is temporarily unfit for military service. This is shown as degree "O" under P, U, L, or S as appropriate and the period of temporary incapacity is stated—e.g., P—"O" for six months.

Method of Assessment.—The medical assessment of any man under this system is based on *functional efficiency at the conclusion of training*. For this reason the *pre-Service* assessment allotted by the civilian medical board is verified by the military medical authorities when the man joins for duty and an *initial* assessment is allotted. At the conclusion of basic training a full medical examination is carried out and a *Service* assessment is made, which remains effective until alteration is considered necessary by a military medical board. To record the findings, in addition to the assessment under each of the seven qualities, age (represented by the last two figures of the year of birth), height, weight, and colour perception standard are recorded in a medical box, in which there is space to enter the reason for an assessment below 2 under P, U, L, or S. The medical box takes the following form:

Y O B	P	U	L	H	E	E	M	S
20	2	2	3	1	1	1	2	2
Ht. 68 ..	P							
C.P. 2 ..	U							
Wt. 135 ..	L	Pes planus—moderate		Medical board: 3/7/46				
	S							

Such an assessment indicates a man who is fit in every way except for a moderate degree of flat-foot, and at a glance it is easy to see that he is suitable for full employ-

ment in any part of the world with mechanized troops but not with infantry (because of L3).

With the introduction of the Pulheems system into the three Services it has been necessary to review medical documentation in general, and a much improved system is being devised for use by all three Services which it is hoped will be introduced in the near future.

Administrative Application of the System

From Table I it will be seen that the degrees of P, U, L, H, M, and S are interpreted and signify suitability for various ranges of employment as follows:

TABLE II

Degree	Functional Capacity	Combatant Capacity	Climatic Restriction
1	Above average	Full	Nil
2	Above average	Full	Temperate
3	Average	Full	Nil
4	Average	Full	Temperate
5	Average	Full	Nil
6	Moderate defect	Restricted	Temperate
7	Moderate defect	Restricted	Nil
8	Marked defect	Restricted	Service in U.K. only
	UNFIT FOR ANY FORM OF MILITARY SERVICE		

The term "restricted" implies service in a role which is not primarily a fighting one.

It is evident, therefore, that the Pulheems code number (i.e., the recorded assessment) provides in effect a complete indication of the fitness, physical and mental, of the individual for employment under varying conditions. It is possible to reduce this code number to a simple two-letter code for use as an employment standard, and so simplify the administrative application of the system.

This has been done within the Army and the Royal Air Force, and the employment standards used by the Army are as follows:

- FE—Employable on full combatant duties in any area in any part of the world (FE—forward everywhere).
- FT—Employable on full combatant duties in any area in temperate climates (FT—forward temperate).
- LE—Normally employable in the lines of communication or base area in any part of the world, but may be employed in the forward area in any role which is not primarily a fighting one (LE—L. of C. everywhere).
- LT—Normally employable in the lines of communication or base areas in temperate climates only, but may be employed in the forward area in any role which is not primarily a fighting one (LT—L. of C. temperate).
- BE—Employable only in the base area in any part of the world (BE—base everywhere).
- BT—Employable only in the base area in temperate climate (BT—base temperate).
- HO—Employable in the protected area in the United Kingdom only (HO—home only).

It has been said that the two essentials required in a system of medical classification are (a) a detailed qualitative estimation of the individual, and (b) a qualitative analysis of the available employments expressed in the same terms.

Under the Pulheems system these two requirements are met. For the Army's purposes employment standards have been worked out in relation to each arm of the Service. For employment forward of the base the standard has been set according to the general functions of the arm, while in base areas it has been determined in relation to the actual employment itself. This difference is necessary to meet the requirements of reinforcement demands.

Minimum Standards: The Infantry Soldier

To conclude my description of the Pulheems system of medical classification and to provide an illustration of the working of the system it is convenient to start with the specifications of the infantry soldier, since it is such men whom every army particularly needs and who must possess the highest standards of physical competence. To be efficient an infantry soldier must have the following functional attributes

P for Physical Capacity—"Must be able to endure severe strain, do heavy physical work, and engage in hand-to-hand combat

These are general capacities derived from a man's whole physical development—his height and weight, his ability to acquire physical stamina with the proper training, his capacity for work, and his general good health

U for Upper Part of the Body, or Upper Limbs—"Must be able to lift and carry heavy loads. Be able to dig and throw hand grenades and use weapons"

To do these things a man must have strong arms, shoulders, and back, and must be able to use his hands with normal dexterity

L for Lower Part of the Body or Locomotion—"Must be able to stand at his post for long hours and march more than 20 miles a day without difficulty"

H for Hearing—"Hearing must be good so that he can understand commands made under difficult conditions and hear suspicious sounds when on night watches"

EE for Eyesight—"Must be able to see the enemy at considerable distance and use his rifle sights with either eye

M for Mental Capacity—"Must be intelligent in order to learn the use of his specialized weapons and field craft"

S for Stability (Emotional)—"Must also be a man of stable temperament with self confidence and determination"

Expressed in terms of Pulheems, the minimum standard permissible for the infantry soldier therefore is

P	U	L	H	E	E	M	S	—Employment Standard
				8	8			
2	2	2	2	—	—	2	2	—FE
				3	3			

Discussion

Under Pulheems the emphasis is placed on the functional capacity of the individual to work rather than on any existing abnormality, whether anatomical or otherwise. It is generally agreed by all concerned that, given a reasonably correct functional assessment of a man's ability to work, a more accurate allocation to suitable employment becomes possible. It is hoped that in the future there will be few, if any, "square pegs in round holes" in the Services.

One of the factors on which there is some diversity of view among medical men is the effect of the age of the individual on assessment, particularly under the P quality. It must be admitted that as one advances in years moderate constitutional defects begin to appear which can easily be recognized on examination, such as increase in weight, rise in blood pressure, cardiac irregularity, and so on, and over the age of 40 years the likelihood of a man or woman being assessed P1 or P2 becomes less and less as age advances. In the absence of such constitutional defects, however, in a man of good physique and with a good previous history there is no reason why an assessment of P2 should not be given to the really fit individual. In an organization such as the Army, the medical officer is inclined to think in terms of "fighting" fitness, and therefore he tends to assess the 40-year-olds and over as P3

rather than P2. It should always be remembered that the employment of an individual must be governed by both his medical fitness and his age, and the latter alone is sufficient to contraindicate posting in a fighting role.

The Pulheems system of medical classification was subjected to some criticism because for the first time in the history of medical categories in the Services it specifically took into consideration the two qualities mental capacity (M) and emotional stability (S) and introduced their routine assessment for each individual. It has even been stated in this connexion that the Pulheems system was little more than a "psychiatric racket" which, it was implied, might be detrimental to and prejudice the chances of men entering the Forces. There can surely be few to-day who would deny that psychiatric disorders are as important as physical diseases, and in the light of increasing knowledge the dichotomy between mind and body appears more and more arbitrary and indistinct. Medical fitness is a *total* problem and we cannot separate the mind from the body. It is hoped that the introduction of Pulheems by the Services will help to underline in the mind of the public as well as in that of the medical profession the importance of regarding the individual as a complete unit, in whom the mental and physical functions must be considered and assessed simultaneously. Service medical officers are trained to use their clinical judgment in assessing an individual as normal or better—i.e., M2 and S2, it is only when there is doubt or any definite indication that the individual is abnormal that psychiatric advice should be obtained.

Within the Services, therefore, it has been possible to introduce a new system of medical classification which, while giving a much more detailed picture of the man's capacity to work, is also very simple in its application and use by non-medical personnel. In the Army, standards have been worked out for all the trades and employment available, and it is hoped to take steps to prove our norms and in the end to obtain some definite information on what is compatible with normal and what is definitely abnormal.

The tendency in the past in the medical world has been to teach the medical student the care of the sick and disabled, little attention being paid to his education in what is considered normal. There are many ways of being "well," but the whole question of just how well a man must be in order to carry out satisfactorily any particular one of the hundreds of jobs that are available in a modern army has never been satisfactorily determined. The present drive towards positive health will, it is hoped, be very materially assisted by the use of Pulheems, since it is evident that an accurate method of assessing the fitness of an individual is a prerequisite of the determination of positive health. It is for these reasons that I suggest that such a system need not be confined to the Services alone and could well be used by industry generally, police forces, and other similar bodies.

It would appear from Service experience regarding medical classification generally that comparatively little attention has been paid to it in the past, and that the systems of classification formerly used have not been understood properly either by medical men or by laymen. Where the employment of men has been considered, a great deal of stress has been placed on welfare, environment, working conditions, and so on, but practically no attention has been given to the question of their fitness for their particular type of employment. It is hoped that academic bodies in the future will consider teaching *methods* of medical classification to medical students and also to postgraduates. It is contended that the concentration on disease in hospital teaching and elsewhere is unwise, and that the time has come when more consideration must be given to health

and fitness and the application of clinical knowledge to its assessment. Almost all medical men are called upon at one time or another to examine men for the Services, and the despairing efforts of the newly qualified medical officer when faced with a group of recruits whose fitness he is expected to assess is well known. The fault lies essentially with the teaching rather than with the new doctor.

One of the difficulties in using any system of medical classification is the wide divergence of opinion among medical men regarding assessment generally and more particularly the influence of various diseases and other morbid conditions on assessment. In the literature which has been produced by the Services on the Pulheems system an attempt has been made to issue some guidance in this matter. It is hoped that with increasing experience this aspect of the subject will be reviewed from time to time and greater precision will be achieved. It remains for civilian bodies to carry the project one stage further. If it is possible to achieve the necessary liaison between civil and military medical authorities there seems to be no reason why in the end all medical men should not be able to allot to each individual the same medical assessment, a development which would be more than welcome to the Services.

Conclusion

The Pulheems system of medical classification has been introduced in the Services to remedy the shortcomings of previous systems used and to facilitate the optimum employment of man-power. Our objectives briefly are: to set up a common system for use by all three Services; to provide a functional assessment of the individual's capacity for work; to assist in expressing the physical and mental attributes appropriate to individual trades and employments within each Service; to allocate men to the employment for which they are most suited in view of their physical, intellectual, and emotional make-up; and to provide a system which is administratively simple to apply in both peace and war.

I consider that the introduction of Pulheems by the fighting Services marks a great step forward in this field of activity. The conception of a uniform assessment of the functional abilities of the population as a whole, whether in terms of war requirements or of industrial potential, is striking enough to require no further elaboration.

ARMY PUBLICATIONS

Pulheems—System of Medical Classification for the Fighting Services, dated November, 1946.

The Application of the Pulheems System of Medical Classification to the Army (W.O. Code No. 1792—restricted).

These pamphlets are in the process of being rewritten, and it is hoped that the first, which deals with the medical aspect entirely, will be available for purchase at H.M. Stationery Office early this year.

I wish to express my thanks to the Director-General of the Army Medical Services, Lieutenant-General Neil Cantlie, C.B., M.C., F.R.C.S., K.H.P., for permission to publish this paper. My gratitude is also due to the Director of Hygiene, Brigadier A. E. Richmond, C.B.E., K.H.S., and my colleagues Lieutenant-Colonel A. N. B. Odber, O.B.E., R.A.M.C., and Major R. B. Stalbow, General List, for much valuable help and criticism in the presentation of this paper.

Offenders who are remanded on bail under provisions of Section 26 of the Criminal Justice Act, 1948, may now be sent to certified institutions or certified houses (among other places) for medical examination and report. The Mental Deficiency (Amendment) Regulations, 1948, which came into operation on Dec. 27, prevent such an offender being received in a certified institution or certified house which is already accommodating the full number of patients for which it has been certified as suitable unless the Minister consents to his reception.

"PALUDRINE" (PROGUANIL) IN PROPHYLAXIS AND TREATMENT OF MALARIAL INFECTIONS CAUSED BY A WEST AFRICAN STRAIN OF *P. FALCIPARUM*

BY

G. COVELL, M.D., D.T.M.&H., D.P.H.

W. D. NICOL, M.B., D.P.M., F.R.C.P.

P. G. SHUTE AND M. MARYON

(From the Malaria Laboratory, Horton Hospital, Epsom, Surrey)

"Paludrine" was first used for the treatment of human malaria at the Liverpool School of Tropical Medicine in 1945 by Maegraith and his colleagues, who published records relating to 22 patients naturally infected with West African strains of *Plasmodium falciparum*, 16 of whom were considered to be suffering from primary attacks. The dosage of paludrine administered varied from 50 to 600 mg. twice daily for 14 days. The clinical response was satisfactory in all cases, and was as rapid in those receiving 50 mg. of the drug twice daily as in those who were given a dosage ten times as great. Owing to difficulties in follow-up it was not possible to determine the radical cure rate (Maegraith *et al.*, 1945).

Subsequently an extensive series of prophylactic and therapeutic trials with paludrine on volunteers exposed to infection with New Guinea strains of *P. falciparum* and on troops suffering from malaria contracted in that area was undertaken by Fairley and his colleagues at the Land Headquarters Medical Research Unit, Cairns, Australia, on the same lines as those previously employed at this centre with mepacrine. Paludrine was found to act as a true causal prophylactic against infections due to New Guinea strains of *P. falciparum*. Radical cure was effected in 41 out of 41 natural and in 46 out of 47 experimentally induced sporozoite infections treated with a ten-days course of 100 mg. of the drug thrice daily. In most cases there was rapid clearance of asexual parasites from the peripheral blood, but, though the overt attack was readily controlled even by very low dosage, the clinical response was described as "not rapid." Gametocytes were not destroyed in the peripheral blood but were rendered non-infective to mosquitoes for a variable period, depending on the size of the dose administered (Fairley *et al.*, 1946).

Since the publication of the Liverpool and Cairns trials a number of prophylactic and therapeutic trials with paludrine have been carried out in India and in Malaya, with generally favourable results. The drug has proved exceedingly useful in both these countries, particularly among labour forces and village populations, where a single-dose treatment of 300 mg. has been generally adopted. It should be noted, however, that the great majority of the subjects treated have been semi-immunes, and there is little evidence regarding the radical cure rate. Chaudhuri (1948) drew attention to the existence in India of strains of *P. falciparum* infections from which are not radically cured by a dosage of 300 mg. of paludrine daily for ten days, and cited the case of a patient who experienced a second overt attack nine days after the completion of treatment and a third attack 11 days later. Other reports from clinicians practising in India and in Malaya indicate that for the treatment of *P. falciparum* infections in non-immune persons paludrine is not entirely adequate in the dosage originally recommended.

In Sardinia, Bettini (1948) treated 94 cases of *falciparum* malaria with 100 mg. of paludrine thrice daily for 10 days

followed by a weekly dose of 100 mg. for three months. The clinical response and clearance of parasites from the peripheral blood were satisfactory, but in 17 of the cases relapses* occurred within this period.

Widely divergent accounts regarding the efficacy of paludrine in the treatment and prophylaxis of malaria have emanated from different parts of Africa, including Kenya, Tanganyika, Rhodesia, Uganda, the Gold Coast, and Nigeria. Some of these have been favourable, whilst in others it has been alleged that the drug has proved unsatisfactory in the treatment of *P. falciparum* infections, in respect of both clinical response and radical cure, as well as for prophylaxis. The most frequent criticism has been that, owing to its slowness of action, serious symptoms have persisted in many cases for three or four days, sometimes longer, necessitating reinforcement of the treatment with mepacrine or quinine.

As the result of trials in the Belgian Congo, van Riel (1948) reported that in a dosage of 100 mg. thrice weekly paludrine failed to act as a causal prophylactic against *P. falciparum* in non-immune subjects constantly exposed to infection. This statement was based on the grounds that one out of 11 persons so treated developed an overt malarial attack on the last day of drug administration and our others did so shortly after this had been discontinued, under conditions precluding the possibility of reinfection. It should be noted, however, that administration of the drug was discontinued approximately 40 hours after the last possible exposure to infection, a period which on Fairley's findings leaves little if any margin of safety and which can scarcely be regarded as sufficient to ensure adequate protection. The clinical response in 156 cases of *P. falciparum* malaria in African labourers treated with 100 mg. of paludrine thrice daily was reported by van Riel to be as satisfactory as that achieved by mepacrine or quinine, but the radical cure rate was not stated.

The investigations recorded below were undertaken in an endeavour to clear up some of the points at issue regarding the use of paludrine for the prophylaxis and treatment of infections with African strains of *P. falciparum*. The strain of parasite used was obtained from a native child resident in Lagos, Nigeria, in November, 1947, and has been maintained at Horton since that date by successive blood and mosquito inoculation. None of the subjects through whom the strain has been passed received paludrine, except the second in the series, who was given 300 mg. of the drug in a single dose on two successive days. The mosquitoes used for transmission were *Anopheles stephensi* (Type), a colony of which was established at Horton during the winter of 1947-8 from specimens imported by air from India. The subjects of the trials were patients in Horton Hospital, all of whom had undergone malaria therapy for eurosyphilis with the Madagascar strain of *P. vivax* or with European strains of *P. falciparum* nine or more years previously but had not been exposed to malarial infection of any kind in the intervening period.

Prophylactic Trials

Twenty-seven patients were arranged in groups as shown in Table I. The patients were infected once weekly over a period of six weeks,† alternate subjects under prophylaxis either being bitten by five to ten heavily infected mosquitoes or receiving by intravenous injection a suspension of the salivary glands of one heavily infected mosquito by the technique described by Shute (1937). Infections were

*Throughout this paper the term "relapse" has been applied to any recrudescence of fever with demonstrable parasitaemia subsequent to the primary attack.

†Except the two individuals under quinine prophylaxis (Group V), who were infected three times only, over a period of three weeks.

TABLE I

Group	No. in Each Group	Drug Administered	Dosage
I	5	Paludrine	100 mg. daily
II	5	"	50 mg. daily
III	5	"	100 mg. twice weekly at 3 to 4 days' interval
IV	5	"	200 mg. once weekly
V	1	Quinine hydrochloride	5 gr. (320 mg.) daily
VI (controls)	5	No drug	10 gr. (650 mg.) daily

given on a different day each week, so as to simulate as closely as possible conditions which might arise in nature. Drug administration was started three days before the first infection in each group, and was continued until six days after the last infection. One or more controls were infected from each batch of mosquitoes used during the course of the experiment. Blood examinations (thick smears) were made twice weekly as a routine, and daily in the case of any rise of temperature above the normal level.

Results

No member of any of the paludrine groups (I to IV) showed parasites in the peripheral blood either during the period of drug administration or subsequently. One member of Group II (50 mg. of paludrine daily) had intermittent pyrexia for four days, starting a fortnight after his first infection. Sub-inoculation of his blood into a non-immune subject proved negative. The donor was found to have only a trace of paludrine in his blood at this time, whereas a few days later the concentration of the drug was of the same order as that of the other four members of the group, the inference being that by some means he had avoided taking the drug regularly as prescribed. Despite the negative results of sub-inoculation and blood examination it is possible that the pyrexia was the result of a partially suppressed malarial infection, but in the circumstances stated this case cannot be regarded as a genuine breakthrough.

Neither of the two individuals under quinine prophylaxis (Group V) showed pyrexia or parasites in the peripheral blood while taking the drug. Both developed overt attacks of malaria after the drug had been discontinued, the first after the lapse of seven days and the second five days later. This is in accordance with the well-established fact that quinine is not a causal prophylactic of malarial infections, its action being suppressive only. All the five control cases developed overt malarial attacks within the normal incubation period, thus demonstrating that each batch of mosquitoes used was infective.

Ten weeks after the cessation of drug administration 18 of the 20 individuals who had been on paludrine prophylaxis were inoculated intravenously with sporozoites of the same strain of *P. falciparum*. All without exception developed overt attacks of malaria within a period of seven to ten days, thus proving their susceptibility to infection with the Lagos strain.

Three members of the laboratory staff were bitten repeatedly while handling heavily infected batches of mosquitoes throughout the period of the investigation, taking no precautions to avoid infection. Each took 200 mg. of paludrine in a single dose twice weekly at three to four days' interval. None of them developed malarial attacks. It is of interest also that two members of the staff who visited Nigeria in November, 1947, were inoculated intravenously in Lagos with a suspension of the salivary glands of a heavily infected specimen of *Anopheles gambiae* caught in a native hut. The species of parasite cannot be stated with certainty, but since the great majority of positive

blood smears examined at this time contained parasites of *P. falciparum* it is more than likely that they were infected with sporozoites of this species. They had each taken 100 mg. of paludrine daily until and including the day before infection, after which the drug was discontinued. Neither developed signs or symptoms of malaria.

From the evidence presented above paludrine has been shown to act as a true causal prophylactic against the Lagos strain of *P. falciparum* in each of the regimes under trial. It is considered, however, that non-immune persons residing in or visiting West Africa should be advised to take not less than 100 mg. of the drug daily for the prophylaxis of malaria. For semi-immune subjects, such as native labour forces and locally recruited Government employees, a weekly dose of 300 mg. is recommended. We do not regard the other two systems tested as offering a sufficient margin of safety.

Therapeutic Trials

Twenty-five patients were arranged in groups as shown in Table II. Each patient was infected by intravenous

TABLE II

Group	No. in Each Group	System of Treatment
I	5	Paludrine 300 mg. once daily for 14 days
II	5	Paludrine 300 mg. twice daily for 7 days
III	5	Paludrine 300 mg. twice daily for 10 days, plus quinine hydrochloride 10 gr. thrice daily on the first day of treatment only
IV	5	Paludrine 300 mg. twice daily for 10 days, plus mepacrine 300 mg. thrice daily on the first day only
V	5	Quinine hydrochloride 10 gr. twice daily for 10 days

inoculation of a suspension of the salivary glands of two specimens from the same heavily infected batch of mosquitoes. Treatment was started in all cases as soon as the temperature reached 100° F. (37.8° C.), provided that parasites had also been seen in the peripheral blood (thick smear).

The results are summarized in Table III. The most striking features brought out by these results are: (1) the

TABLE III

Group	Average Duration of Fever*	Average Duration of Parasitaemia* (Asexual)	Subsequent History
I (P. only)	76 hours	3.2 days	All 5 cases relapsed within 3 weeks and were treated with 300 mg. paludrine twice daily for 10 days. A second relapse occurred in one case
II (P. only)	68 "	3.0 "	Four out of 5 cases relapsed within 3 weeks and were treated with 300 mg. paludrine twice daily for 10 days. A second relapse occurred in 2 cases
III (P. plus Q.)	78 "	2.0 "	No relapse (observed 3 months)
IV (P. plus M.)	50 "	2.5 "	" " "
V (Q. only)	55 "	2.5 "	" " "

* After beginning of treatment.

P. = Paludrine. Q. = Quinine. M. = Mepacrine.

conspicuous failure of paludrine unaided to effect radical cure; (2) the absence of relapse following courses of paludrine reinforced with quinine or mepacrine on the first day of treatment, and of quinine alone; and (3) the rapid termination of the clinical attack effected by reinforcement of a paludrine course with mepacrine on the first day of treatment.

Effect of Paludrine on Gametocytes.—Gametocytes were observed, often in very large numbers, in the peripheral blood of eight of the nine patients who experienced relapses, for which they were treated with 300 mg. of

paludrine twice daily for ten days. Mosquitoes were allowed to feed repeatedly on the two patients who showed the greatest density of gametocytes over a period of 24 days, but none became infected. By this time the gametocytes had become too scanty for infection to occur even had no drug been given.

Discussion

The chief objectives in the treatment of *P. falciparum* infections are: (1) Termination of the clinical attack with the least possible delay. In countries where malignant tertian infections are prevalent this is an essential requirement, particularly when, as often happens, the patient has been ill for some days before the beginning of specific treatment. (2) Prevention of relapses, which may be little less dangerous to life than the primary attack. (3) Sterilization of gametocytes for as long a period as possible. (4) Low toxicity on the part of the drugs used for treatment and for prophylaxis.

The investigations here recorded have confirmed the findings of others working in different countries that the action of paludrine on the clinical attack in malarial infections is generally less rapid than that of mepacrine or quinine, and have shown that, though it acts as a true causal prophylactic of the Lagos strain of *P. falciparum*, it cannot be relied upon, unaided, to effect radical cure of infections with that strain. When administered in sufficient dosage however, it effectively sterilizes gametocytes for as long as these are present in the peripheral blood in numbers sufficient to infect mosquitoes, while its toxicity is of a lower grade than that of any other known antimalarial drug.

Mepacrine, when administered in the dosage now usually prescribed—i.e., starting with a "loading dose" of 600 to 900 mg. on the first day or first two days of treatment and continuing at 300 mg. daily for five to seven days—will effect a rapid termination of the clinical attack and a high rate of radical cure of *P. falciparum* infections. It does not, however, sterilize gametocytes, and its toxic effects though of rare occurrence, are by no means negligible. This applies particularly to the so-called mepacrine psychosis which may evoke symptoms of mental aberration or even of manic-depressive excitement. The yellow coloration of the skin which sometimes follows a course of mepacrine is an additional disadvantage.

Quinine, when administered in a daily dose of 20 to 30 gr. (1.3 to 2 g.) over a period of seven to ten days, will like mepacrine, ensure in most cases a rapid termination of the clinical attack and a high radical cure rate. It has no effect on the infectivity of gametocytes. A greater disadvantage, however, is its long-recognized association with the precipitation of blackwater fever. Findlay and Stevenson (1944) have recorded a marked reduction in the incidence of this disease following the substitution of mepacrine for quinine in the treatment of *P. falciparum* infections among British troops stationed in West Africa.

We have shown that reinforcement of a course of paludrine 300 mg. twice daily with mepacrine 900 mg. given in three doses on the first day of treatment brings about rapid termination of the clinical attack and also results in a high rate of radical cure.* It does not seem likely that a single day's reinforcement with mepacrine will cause mental disturbances, which occur almost exclusively towards the end of a full mepacrine course or during the first week after this has been completed. Since paludrine in doses of 300 mg. twice daily for ten days

*It is possible that reinforcement with 600 mg. of mepacrine would prove sufficient for this purpose.

effectually sterilizes gametocytes, this course, reinforced with mepacrine in massive dosage on the first day of treatment, seems more likely to fulfil all the requirements listed above than any other form of treatment available. We would advise, however, that such a course be followed up by a maintenance dose of 100 mg. of paludrine daily for the ensuing six weeks, in order to cover the period during which *P. falciparum* relapses are most likely to occur. In endemic areas where strict paludrine prophylaxis is in force the patient would come under this regime automatically.

Summary

An account is given of a series of prophylactic and therapeutic trials with paludrine carried out at Horton Hospital, Epsom, against a strain of *P. falciparum* obtained from a native child resident in Lagos, Nigeria.

Paludrine was found to act as a true causal prophylactic of infections with this strain of parasite. The prophylactic dosage recommended for non-immune adults exposed to malarial infection in West Africa is 100 mg. daily.

Paludrine controlled the clinical attack caused by infections with this strain, but its action in this respect and in clearance of asexual parasites from the peripheral blood was somewhat less rapid than that of mepacrine or quinine.

Paludrine unaided failed to effect radical cure of infections with this strain, a finding in marked contrast with the results achieved by Fairley *et al.* (1946) in their researches on New Guinea strains of *P. falciparum*.

Radical cure of the Lagos strain of *P. falciparum* has apparently been effected with (a) 300 mg. of paludrine twice daily for 10 days, reinforced with 900 mg. of mepacrine given in three doses on the first day of treatment (6 cases); (b) 300 mg. of paludrine twice daily for 10 days, reinforced with 30 gr. (2 g.) of quinine hydrochloride given in three doses on the first day of treatment (5 cases); and (c) 10 gr. (650 mg.) of quinine hydrochloride twice daily for 10 days (5 cases).

Following a course of 300 mg. of paludrine twice daily for 10 days gametocytes were rendered non-infective to mosquitoes for as long as they continued to be present in the peripheral blood in sufficient numbers for infection to occur.

Reinforcement of a course of 300 mg. of paludrine twice daily for 10 days with 900 mg. of mepacrine administered in three doses on the first day of treatment shortened the average duration of pyrexia and clinical symptoms by approximately twenty-four hours.

It is considered that such a course, followed by a maintenance dose of 100 mg. of paludrine daily for the ensuing six weeks, would fulfil the main objectives in the treatment of *P. falciparum* malaria infections—namely, rapid termination of the clinical attack, a high radical cure rate, sterilization of gametocytes, and minimum risk of injurious side-effects.

The Secretary of State for Scotland has appointed Mr. T. D. Haddow to be an Under Secretary in the Department of Health for Scotland. Mr. Haddow, who is 35 years of age, was educated at Watson's College and Edinburgh and Cambridge Universities. He had the distinction of taking first place in the 1935 competition for entry into the administrative grade of the Civil Service. He was appointed to the Department of Health for Scotland in October, 1935, as an Assistant Principal, promoted to the rank of Principal in 1940, and to Assistant Secretary in 1943. He was closely associated with the preparatory work in connexion with the National Health Service. Under the auspices of the Commonwealth Fund of New York, Mr. Haddow is at present in the U.S.A. studying the administration of public health in that country, and he will complete these studies before returning to take up his new appointment.

INTRAVENOUS "PALUDRINE" (PROGUANIL)

BY

R. N. CHAUDHURI, M.B.Cal., M.R.C.P.Ed.,
T.D.D.Wales

Professor of Tropical Medicine

AND

H. CHAKRAVARTI, M.B.Cal.

Assistant Research Officer

School of Tropical Medicine, Calcutta

In the spring of 1947 we received a supply of paludrine acetate (soluble proguanil) for intravenous use in the treatment of malaria. This preliminary report is a record of its employment in 11 patients admitted to the hospital attached to this institution, one of them being transferred from another hospital. All were Indians, nine males and two females, ranging in age from 9 to 60 years. The duration of illness was four days or less in nine cases and about a week in two, but in none had any antimalarial treatment been given before admission. *Plasmodium falciparum* infection was predominant, being present in 8 cases, while two had *P. vivax* and one had mixed infection. Four patients were gravely ill with pernicious symptoms, four had heavy parasitic infection with frequent vomiting, while three had what may be called ordinary malaria without any complication.

Paludrine acetate* was supplied in 5-ml. ampoules, each containing 100 mg. of the drug. As it was sent to us for experimental trial there were no instructions regarding dosage, and so we had to proceed cautiously, starting with 25 mg. and increasing to 400 mg. in a single injection. In four cases paludrine was given both orally and intravenously.

Case Reports

Case 1.—A boy aged 14, weight 70 lb. (31.75 kg.), was admitted on April 16, 1947, for remittent fever of four days' duration with severe headache. On admission his temperature was 100.2° F. (37.9° C.). Liver and spleen were not palpable; blood showed *P. falciparum* rings. On the following day, while the temperature was 105° F. (40.6° C.), 25 mg. of paludrine was given intravenously. The blood pressure was 102/45 mm. Hg before and 104/50 five minutes after the injection. On the second day of the injection the temperature was almost normal, but next day it shot up to 104.5° F. (40.25° C.), and remained at about this level for five days and thereafter was of intermittent type. The blood was negative on the third day and

FIG. 1.—Temperature chart of Case 1

crescents appeared on the sixth day. On the ninth day, when the temperature was still high, *P. falciparum* rings reappeared in the blood and the spleen became palpable when 50 mg. of paludrine was given intravenously twice daily for two days. This controlled the fever in 60 hours and cleared the blood of asexual parasites in 48 hours (Fig. 1). The blood pressure

*Paludrine acetate has now been replaced by paludrine lactate, which is more soluble and less irritant. An ampoule of 2 ml. contains 100 mg. of the drug. We have used it intramuscularly with satisfactory results, which will be published later.

before and after the injections showed little or no variation. The patient was subsequently under observation for eight months, during which period he had no recurrence of fever.

Case 2.—A man aged 50, weight 90 lb. (40.8 kg.), was admitted on April 22, 1947, with a history of relapsing *P. vivax* malaria, the duration of the present attack of fever being two days. Blood showed *P. vivax* rings, schizonts, and gametocytes in large numbers. The temperature on admission at 10 a.m. was 99.4° F. (37.4° C.), but it shot up to 106° F. (41.1° C.) at 2 p.m., when 50 mg. of paludrine was given intravenously followed by one tablet (100 mg.) thrice daily for five days. The blood pressure was 170/85 mm. Hg before and 150/80 after the injection. The temperature was slightly raised on the following day and became normal on the day after, while the blood was clear of asexual parasites in 48 hours.

Case 3.—A man aged 34, weight 100 lb. (45.35 kg.), was admitted on May 2, 1947, with a history of fever on alternate days. The spleen was palpable and blood showed *P. vivax* parasites in large numbers. On the 6th he was given three injections of paludrine, 100 mg. each, at intervals of four hours, with a satisfactory clinical response, the temperature becoming normal in 24 hours and the blood parasite-free in 72 hours.

Case 4.—A man aged 60, weight 88 lb. (39.92 kg.), was admitted on July 23, 1947, as a case of enteric fever of about ten days' duration. He was looking toxic and dehydrated, and his general condition was low. As he was also semiconscious it was difficult to feed him. The spleen was palpable and the blood showed *P. falciparum* rings +++ and scanty crescents. Paludrine 100 mg. was given intravenously at 2, 6, and 10 p.m. and 2 a.m., and was well tolerated. The blood pressure before and after each injection was as follows:

	Before	After
1st injection	78/55 Hg	80/58 Hg
2nd "	70/50 Hg	75/55 Hg
3rd "	80/55 Hg	80/60 Hg
4th "	80/55 Hg	80/58 Hg

The patient became fully conscious on the following day and took food much better. The temperature became normal after 32 hours and no asexual parasites were seen after 48 hours, while crescents persisted. There was slow but steady improvement in the general condition, but after about three weeks, while still in the hospital, he had a relapse, for which paludrine was given in doses of one tablet thrice daily for ten days with good response. He was followed up for the next six months, during which period he had no fever.

This was a serious case of *P. falciparum* malaria in an old man with symptoms simulating typhoid fever. Four intravenous injections of paludrine, 100 mg. each at intervals of four hours, had an immediate response.

Case 5.—A man aged 20, weight 90 lb. (40.8 kg.), was admitted to the Medical College Hospital under Dr. J. C. Banerjee on Aug. 23, 1947. The history was that he had a sudden attack of fever on the 20th but carried on with his work until the 22nd. On the following day his fever was high, and he had seven or eight bilious vomits and five or six loose stools with mucus. His condition rapidly deteriorated; he became unconscious at 3 p.m. and was brought to the hospital at about midnight. Blood examination showed *P. vivax* rings. He was given an intravenous injection of paludrine, 100 mg., followed by two tablets of the drug by nasal tube thrice daily for five days. After two more paludrine injections on Aug. 27 and 28 the temperature became normal, but he still remained almost unconscious. On the 30th he was transferred to this hospital along with other patients to make room for casualties due to communal riots in the city. On examination the patient was in a lethargic state, being unable to hear, talk, eat, or even recognize his own mother. At times he was restless, but there was no rigidity or paralysis. Reflexes were normal, pupils equal and reacting, and fundus oculi healthy. The spleen was palpable and the blood pressure 85/55 mm. Hg. Stools passed involuntarily. Blood showed crescents daily from Sept. 5 to 17, and also scanty *P. falciparum* rings on the 8th and 9th, but with no rise of temperature. No antimalarial drug was given and he was fed by nasal tube. After ten days of vegetative existence he began to improve mentally and physically and gradually regained consciousness. He could then sit up and take his food himself and speak, though indistinctly, but developed volitional tremors. At this stage he was taken back

to the Medical College Hospital, where he made good progress except for an attack of *P. vivax* malaria. He visits us periodically, and up to now has been normal.

This patient was desperately ill with cerebral malaria and had apparently both *P. falciparum* and *P. vivax* infections, which responded well to paludrine given intravenously and by the nasal route; but symptoms suggestive of encephalitis developed and he remained in that stage for several weeks. These symptoms appeared to be a sequel of cerebral malaria and not due to large doses of paludrine. It is of interest, however, to note that, despite this dosage, the patient had an early *P. falciparum* relapse without fever and later *P. vivax* relapse with fever while in hospital.

Case 6.—A man aged 40, weight 120 lb. (50.43 kg.), was admitted on Sept. 30, 1947, with a history of high continuous fever for three days, with intense headache and frequent vomiting. His general condition was low, temperature 102.4° F. (39.1° C.), spleen just palpable, and tongue coated and dry. The blood showed *P. falciparum* rings +++. An intravenous injection of 200 mg. of paludrine was given immediately, followed by two more injections of 100 mg. each at intervals of four hours. The temperature became normal three days after the injections, although the blood was negative on the second day.

Case 7.—A man aged 30, weight 75 lb. (34 kg.), was admitted on Oct. 3, 1947, for remittent fever and repeated vomiting of about a week's duration. The spleen was palpable and the blood showed *P. falciparum* rings +++. Soon after admission he had a severe rigor, which was considerably relieved by an intravenous injection of 5 ml. of 10% calcium gluconate. As he was unable to retain anything by mouth he was given an intravenous injection of 300 mg. of paludrine. On the third day he became afebrile and the blood was free of rings.

Case 8.—A man aged 20 was admitted on Oct. 9, 1947, with fever and frequent vomiting that started the same morning. He had had *P. vivax* malaria three weeks previously and been treated with "chloroquin." The spleen was just palpable and blood showed *P. falciparum* rings +++. Next day, when the temperature was 105° F. (40.6° C.), he was given an injection of 400 mg. of paludrine, followed orally by 100 mg. thrice daily for three days. On the 13th he was afebrile and the asexual parasites had disappeared. No untoward effect was observed, and the blood pressure before and after the injection was 102/65 and 105/65 mm. Hg.

Case 9.—A woman aged 25, weight 87 lb. (39.46 kg.), was admitted in the evening of Oct. 9, 1947, with a history of high fever for four days and of unconsciousness the night before. On admission her temperature was 103° F. (39.4° C.). She was conscious but dazed, and complained of intense headache and frequent vomiting. The spleen was palpable and blood showed *P. falciparum* rings +++. Paludrine, 400 mg., was given intravenously on the following day. After about 6 ml. had been injected rather rapidly she complained of a hot sensation all over the body and began to sweat. This symptom passed off soon and the injection was completed. The blood pressure before and after the injection was 120/65 and 120/70 mm. Hg respectively. Subsequently she complained of pain along the course of the injected vein up to the axilla, and this persisted for about four days. The temperature became normal in 56 hours and the blood free of parasites in 28 hours.

This patient had vasomotor reactions after part of the injection given rapidly. Probably she also had some local phlebitis.

Case 10.—A boy aged 15, weight 82 lb. (37.19 kg.), was admitted on Oct. 9, 1947, for fever and excessive vomiting for two days. His condition on admission was low; he was very thirsty but was unable to retain anything. The pulse was fast and soft, urine scanty, and temperature 100.4° F. (38° C.). The spleen was palpable, and the blood showed *P. falciparum* rings +++. Paludrine, 400 mg., was given intravenously followed by one 100-mg. tablet thrice daily for four days. There was a striking improvement in the patient's condition; the temperature was normal and the blood became parasite-free after 36 hours.

Case 11.—A girl aged 9 was admitted on Oct. 31, 1947, with a history of high continuous fever for three days, starting with

chill and rigor and persistent vomiting. She had been delirious and restless on the previous night, and on admission was semi-conscious, with a temperature of 104° F. (40° C.), rising to 106° F. (41.1° C.) soon after. The pulse was feeble and very rapid, about 160 (?) a minute, while the respiration was hurried and laboured. A few scattered rales and rhonchi were heard in the lungs. The heart sounds were short and weak; blood pressure 120/60 mm. Hg. The blood showed *P. falciparum* rings. She was immediately given an injection of 100 mg. paludrine; five minutes after the injection the blood pressure was 122/60. Another injection was given after four hours, and the treatment also included sponging and the administration of oxygen, fluids, glucose, and nikethamide injections. The condition steadily deteriorated, and she died 16 hours after admission.

Discussion

Dosage.—Antimalarial drugs are given parenterally only when for any reason, such as loss of consciousness or persistent vomiting, the patient is unable to swallow or retain them, and as soon as these symptoms are controlled the drugs are continued orally. These indications were present in 8 out of 11 cases in this series. Paludrine injections were first tried in two uncomplicated cases of malaria. In one, that of a boy of 14 with *P. falciparum* infection, a dose of 25 mg. had no effect on the temperature, which continued unabated for several days, nor on the parasite, crescents appearing on the sixth day and *P. falciparum* rings reappearing on the ninth day. Both, however, were controlled with 200 mg. of paludrine (50 mg. given twice a day for two days) in about 48 hours after the injection. The other case was heavily infected with *P. vivax* malaria and was treated with 50 mg. intravenously, followed by oral paludrine, one 100-mg. tablet thrice daily for five days. This brought the temperature to normal and cleared the blood of parasites within 48 hours of the injection.

As there were no untoward effects from these injections it was decided to increase the dose in the cases that came afterwards. Most of them happened to be *P. falciparum* infections complicated by cerebral or gastro-intestinal symptoms. At first the dose was 100 to 200 mg. repeated two to three times a day at four-hourly intervals; later it was one of 300 mg. and ultimately 400 mg. These patients therefore received by injection, either in a single dose or in repeated doses, 300 to 600 mg. of paludrine. To be on the safe side, these injections were accompanied in four cases by paludrine orally.

Effect on Temperature and Parasites.—The immediate effect of the increased dosage in 7 out of 9 patients was striking. In Cases 3, 4, 6, 7, and 9, which had injections only, the blood became clear of parasites in 24 to 48 hours and the temperature became normal in 32 to 72 hours; there was also improvement in their general condition. This was especially noticeable in Case 4, that of a man of 60, who was semiconscious and in a toxic state on admission. After receiving 400 mg. in twelve hours he soon became fully conscious and began to take his food much better. Cases 8 and 10, which had oral paludrine in addition to injections, showed equally good response even before the drug by mouth could have exerted its full effect.

Paludrine had no such effect in the remaining two cases. One of them (Case 5) had typical cerebral malaria, and, though the mixed *P. falciparum* and *P. vivax* infection was controlled by giving the drug intravenously as well as by the nasal route, he remained unconscious for some time and developed signs indicative of encephalitis; but eventually he recovered fully in spite of subsequent relapses. The other case (No. 11) was that of a girl of 9 with hyperpyrexia and delirium from *P. falciparum* infection who was admitted in a state of failing circulation. Paludrine by injection (two doses of 100 mg.), with stimulants, had no

effect whatsoever, and she died within 16 hours of admission. The patient was brought in in a moribund state, and it is difficult to judge the effect of the drug in such a case.

Other Effects.—Practically all the patients were weak and undernourished before the present attack of malaria. Only one of them weighed above 100 lb. (45.35 kg.). One was below 10 years of age and two were 50 years or over. The blood pressure was low in two cases—viz., 78/55 and 85/55 mm. Hg. Yet paludrine had no adverse effect, and the blood pressure remained remarkably constant even after three or four injections given at four-hourly intervals. One patient (Case 9) complained, while the injection was being given, of a hot sensation all over the body and began to sweat; these symptoms soon passed off, and the blood pressure remained unaffected. Subsequently she complained of pain along the course of the injected vein up to the axilla, which lasted for four days. Later we encountered another patient, not included in this series, who also complained of similar pain, which persisted for five or six days after the injection of 100 mg. The pain was mild but uncomfortable, and was possibly due to some local phlebitis.

Summary

Paludrine acetate (soluble proguanil) was tried intravenously as an experimental measure in a series of 11 cases of malaria, all of which except two had *P. falciparum* infection. The majority of the patients had either cerebral or gastro-intestinal complications and were not suitable for oral medication. Four of them were gravely ill.

Doses varied from 25 to 400 mg., and were repeated in a few cases. The total amount of paludrine injected ranged from 200 to 600 mg. per case.

This series was too small for determination of the optimum dose, but in the majority of cases a dosage of 200 to 400 mg. controlled the temperature and cleared the peripheral blood of asexual parasites in two to three days.

One patient admitted in a moribund state died. Another patient, with typical cerebral malaria, remained unconscious for several days and later developed signs and symptoms of encephalitis, from which, however, he recovered completely.

The injections were well tolerated, but one patient (and another not included in this series) had some phlebitis of the injected vein, which subsided in a few days.

Our thanks are due to Messrs. Imperial Chemical Industries (India), Ltd., for the supply of paludrine acetate; to Dr. J. C. Banerjee, of the Calcutta Medical College, for information about Case 5; and to the Indian Research Fund Association for a grant to carry out clinical trials with recent antimalarials.

In the annual report of the Central Midwives Board for the year 1947-8 reference is made to the changes and improvements which have been brought about in recent years in the midwifery services of the country. Revision of the rules has been considered, and the Board has come to the conclusion that while some of the rules are still necessary they should be phrased in such a way that "they indicate a general standard of professional work which it is desirable to maintain rather than set out in precise detail the methods by which such a standard should be attained." During the year the Board decided to incorporate training in analgesia in the ordinary syllabus of training for a pupil midwife. Up to March 1, 1948, some 11,759 midwives possessed either the Board's certificate of proficiency or a certificate issued by a training institution. The Royal College of Obstetrics and Gynaecology was asked by the Board to report on the suitability of trichlorethylene as an analgesic for use by midwives, but the Council of the Royal College was unable to recommend that this substance should be used by midwives without supervision. The number of midwives who were practising in 1947 was 17,400. This maintains the steady increase recorded since 1942, when the figure was 15,615. The number of pupil midwives who were successful at the first examination was a record—3,832 compared with 3,486 in 1946. Wastage during training averaged 10.4% of the registrations. It is interesting that for the first time since 1902 there was no longer any midwife practising out of the 12,500 untrained women who were admitted to the Roll by virtue of having been in *bona fide* practice as midwives for a year or more before the passing of the Midwives Act, 1902.

PLASMA-CELL MASTITIS

REPORT OF A CASE WITH BILATERAL INVOLVEMENT

BY

MAX CUTLER, M.D.

(From the Chicago Tumor Institute)

Since plasma-cell mastitis was first described (Cheate and Cutler, 1931) this peculiar inflammatory condition of the breast has become a subject of increasing interest. The fact that fewer than fifty cases are recorded in the literature under this title attests to the rarity of the disease. Its importance lies in its marked similarity to cancer. In fact, until recently radical mastectomy was almost invariably performed without biopsy because the clinical picture seemed so classical.

The purpose of this communication is to review the literature and report a case with bilateral involvement, an aspect which so far as I am aware has not been previously recorded.

Case Report

A married woman* aged 37, with two children, aged 5 and 7, was first seen on Oct. 28, 1932. Two weeks previously she felt a sudden pain in the right nipple accompanied by swelling and tenderness of the right breast. Three days later the swelling, pain, and tenderness diminished and the patient felt a mass in the centre of the breast.

Examination disclosed the breast to be considerably larger than the left, and the surface temperature was raised. In the centre was a firm solid movable mass about 8 cm. in diameter attached to the overlying skin. Several enlarged movable lymph nodes were present in the right axilla. The left breast seemed normal. A diagnosis of diffuse duct carcinoma was made and, because of the possibility of inflammatory carcinoma, pre-operative irradiation was given as follows: right breast, 16,000 mg.-hours with 4 g. of radium, filtration 1 mm. platinum, distance 6 cm. through a round portal 10 cm. in diameter—4,000 mg.-hours for four days. Right axilla, 12,000 mg.-hours with 4 g. of radium, filtration 1 mm. platinum, distance 10 cm. through a round portal 10 cm. in diameter—4,000 mg.-hours daily for three days. The last radiation treatment was given on Nov. 2, 1932. Several days after completion of treatment the tumour began to regress rapidly. The patient was scheduled for radical mastectomy on Nov. 8, 1932.

In consultation with Dr. Richter just before the operation I suggested that the clinical picture, especially the rapid regression under irradiation, raised doubts about the diagnosis, and it was decided to perform a biopsy. The residual mass was excised and showed no evidence of carcinoma. The gross character of the lesion was most unusual. There were several small soft semi-fluid yellowish foci having a xanthomatous appearance, and numerous dilated ducts which exuded a brownish creamy material. Microscopically, foci of lymphocytes and solid masses of plasma cells with occasional foreign-body giant cells were seen, but no signs of carcinoma. Simple mastectomy was performed with the same gross and microscopic findings.

On July 6, 1939, six years and eight months after removal of the right breast, the patient complained of pain, tenderness, and nodularity in the left breast which recurred periodically at monthly intervals. These episodes corresponded to the menstrual cycle, although menstruation had ceased some years before in connexion with a hysterectomy. The ovaries were not removed. Examination disclosed that the left breast was enlarged, tender, and the seat of diffuse nodularity. In July, 1946, Dr. Richter performed a local excision. The gross and microscopical features of the specimen were those of plasma-cell mastitis.

Comment

This case presents several interesting and unusual features—the involvement of the second breast almost seven years

after the first, the cyclic periodic increase and recession of symptoms, and the marked radiosensitivity of the lesion. The clinical and pathological picture which created a problem in diagnosis and treatment is best presented by the following notes I made on the morning of Nov. 8, 1932, the day of the first operation.

"Just before operation, in conversation with Dr. Richter, it was my opinion that there was some doubt about the presence of cancer, and I recommended local excision of the residual mass and frozen section. This was done. The gross character of the lesion was most peculiar, there being several areas of soft semi-fluid xanthomatous foci, also numerous dilated ducts exuding a brownish creamy material. There were no definite chalky streaks as one finds in carcinoma. Frozen sections failed to show definite evidence of carcinoma. Microscopical examination shows numerous foci of plasma cells and lymphocytes with occasional giant cells. It is my opinion that we are dealing with plasma-cell mastitis. It is interesting to note, on reviewing the history, that the condition started with acute symptoms consisting of sharp pain at night and that upon examination there was elevation of surface temperature over the breast. It is also important that the whole duration of this lesion was only two weeks. Furthermore, the very marked and rapid diminution in size of the mass following irradiation is more in favour of an inflammatory process. All the evidence favours a benign lesion."

Historical

In 1925 Ewing began to call attention to an unusual lesion of the breast which presented the gross and microscopical features of a curious inflammatory process. Almost without exception a radical operation had been performed under a clinical diagnosis of cancer. Because of the presence of solid masses of plasma cells beyond those seen in the usual inflammatory lesions, Ewing suggested the name "plasma-cell mastitis." I was associated with Ewing in the laboratory of the Memorial Hospital at the time and undertook to study the clinical picture associated with this condition; I found in the records of the Memorial Hospital only ten cases. The clinical features associated with this pathological state were so striking as to make it obvious that we were dealing with a more or less specific clinical and pathological entity. The results of this study were published by Cheate and Cutler in 1931.

In 1933 Adair published a detailed study of the same cases and reached essentially similar conclusions. Adair suggested that the lesion may be precancerous and advised local excision as the best treatment. In the same year I reported the case of a woman aged 50 with the classical clinical signs of the disease (Cutler, 1933). Eight weeks after the onset a residual tumour mass was excised which showed the typical gross and microscopical features of plasma-cell mastitis. In 1939 Rodman and Ingleby reported a case which showed marked shock and toxæmia after radical breast amputation under an erroneous diagnosis of cancer. They consider that the presence of colostrum-like cells and fatty acid crystals suggests that the disease may be due to the action of enzymes causing a splitting of milk-like substances secreted under certain conditions in breasts of non-pregnant women. These studies, they think, point to the possibility that the products of milk disintegration may constitute the causative agent.

Cromar and Dockerty (1941) reported twenty-four cases seen over a period of thirty years in the Mayo Clinic. A clinical diagnosis of cancer had been made in seventeen of the cases. The low incidence of the disease was emphasized by these authors and by Harrington (twenty-four cases of plasma-cell mastitis among 12,000 breast cases). In 1943 Payne, Strauss, and Glasser reported two cases under the title of "mastitis obliterans" and presented their reasons for preferring this term to that of plasma-cell mastitis. The same year Lübschitz (1943) reported the case

*This patient was referred to me for consultation by Dr. H. M. Richter, through whose courtesy her case is reported.

of a patient who died in shock twenty-four hours after radical mastectomy. A biopsy had been erroneously interpreted as cancer, hence the radical operation. In 1944 Parsons, Henthorne, and Clark found five cases of plasma-cell mastitis among 1,500 breast specimens. Two of the cases are reported with clinical data. Gaston (1947) added three new cases. One patient had a bloody discharge from the nipple and in another there was a coexistent comedo-carcinoma with metastasis to axillary lymph nodes. Gaston suggests that while plasma-cell mastitis is usually benign the disease has malignant potentialities and can develop into either a comedo-carcinoma or a malignant plasmocytoma.

Related Conditions

In 1931 I searched the literature for references to acute and subacute inflammation of the non-lactating breast with the view of finding examples of plasma-cell mastitis reported under other titles. I found the case presented by Courtin (1900) before the Bordeaux Medical and Surgical Society in 1899. The patient was 50 years of age and the menopause had occurred four years previously. The tumour had been present for three months and showed most of the classical features of cancer. It was firm and fixed to the skin. The nipple was retracted and the axillary lymph nodes were enlarged. The tumour was, however, exquisitely tender, and the skin was reddened and warm. The treatment consisted of local hot applications. After four weeks the tumour had disappeared and there was no evidence of disease. In the discussion Coquet referred to a similar case which he had observed.

In 1932 Cohn and Bloodgood reported a series of cases of non-suppurative chronic lactation mastitis, some of recent origin, others occurring months or years after pregnancy. Microscopical study of the sections revealed signs of residual lactation in all the cases.

In 1909 Ingier described a low-grade inflammatory lesion of the breast under the term "mastitis obliterans." From a review of the case, however, it is clear that, although the microscopical features have some resemblance to plasma-cell mastitis, the clinical picture is totally different. Thus the patient developed an abscess in a lactating breast unlike plasma-cell mastitis. This clinical picture generally does not simulate mammary cancer.

In the case reported by Hoerz (1910) as mastitis obliterans a tumour mass developed following trauma. This too is not the clinical picture of plasma-cell mastitis, but rather of traumatic fat necrosis. In 1933 Schultz reviewed the earlier German cases and added a case of his own under the term "mastitis obliterans."

From an analysis of the published data it seems clear that some of the cases published as "mastitis obliterans," such as those of Ingier and of Hoerz, have no real similarity to plasma-cell mastitis, at least clinically, whereas others, such as those reported by Payne, Strauss, and Glasser, represent the same condition that we call plasma-cell mastitis.

The case published by C. W. Cutler (1934) is disquieting. His patient was a woman aged 49. Local excision was performed for a tumour of the left breast, and a microscopical diagnosis of plasma-cell mastitis was made. Nine months later a growth with a similar microscopical structure appeared in the right vocal cord, and subsequently similar lesions appeared in the sterno-clavicular joint, upper portion of left breast, and right antrum. The question arises whether this is a true example of plasma-cell mastitis or one of plasmocytoma. The question must be left open for the present, but the weight of evidence favours the latter diagnosis.

Certain conditions which have some similarity to plasma-cell mastitis and from which it must be distinguished are: lactation mastitis with or without abscess formation, traumatic fat necrosis, and plasmocytoma. Diffuse duct carcinoma, especially when associated with inflammatory signs, has already been noted.

Distinguishing Features

Clinical Features.—A breast which is not the seat of lactation may become acutely inflamed. The onset is sudden, with pain, tenderness, and redness of the skin. At first the whole breast is swollen and the axillary nodes are enlarged and tender. Usually there is some rise in temperature and sometimes there are chills. A creamy discharge from the nipple is not uncommon. The acute symptoms soon begin to subside, and as time progresses the process enters the second or subacute stage. In this interval the pain and tenderness diminish and the swelling of the breast decreases, leaving a diffuse nodularity. After a relatively short period the subacute signs disappear and the disease enters a chronic stage, which is generally prolonged. When all the acute and subacute signs of inflammation have disappeared there remains a discrete, hard, solid-residual mass with attachment to the overlying skin and often retraction of the nipple. The axillary nodes are usually enlarged and firm. It is during the latter part of the subacute stage and more particularly during the third or chronic stage that the breast presents the classical clinical picture of mammary cancer, rendering a diagnosis of cancer almost imperative, and it is only by eliciting from the patient the details of the initial inflammatory phases of the disease that an error in diagnosis is avoided and the patient saved from a radical mastectomy.

Gross Features.—On cross-section one sees numerous dilated ducts and minute cysts which under pressure exude a thick creamy puriform material. The fat, fibrous tissue, and epithelial elements show a peculiar induration. The tissue has an unusual pinkish inflammatory appearance. There are radiating strands of dense translucent fibrous connective tissue. In some portions there may be soft semi-necrotic greyish areas and xanthomatoid foci, 1 to 3 mm. in diameter, often projecting from the cut surface. The induration and resistance of the tissues simulate carcinoma, but even in the most dense portions one fails to find the classical cicatricial tissues or chalky points that are characteristic of carcinoma. Furthermore, the process is diffuse and does not form a definable tumour that can be limited from the remainder of the breast.

Microscopical Features.—The affected portions of the breast exhibit an active acute and subacute exudative inflammation with numerous leucocytes, lymphocytes, and plasma cells. The process is diffuse and involves both the glandular and the interstitial tissues. The exudate is especially prominent around the ducts and acini, where the cellular reaction may consist almost exclusively of plasma cells. Foreign-body giant cells are often encountered in the centre of these foci. In some instances they are numerous and in others they are few or altogether absent. The dilated ducts are filled with and distended by desquamated epithelial debris. The epithelial cells undergo an intense hyperplasia, which may be so pronounced as to give rise to a suspicion of carcinoma. In the frozen section such areas can be very confusing and may lead to a diagnosis of carcinoma.

Diagnosis

The diagnosis is comparatively simple if the patient is examined during the first or acute stage. In the later stages, when the inflammatory signs have subsided, diagnosis is more difficult and errors are common. The most important

aid in differentiating this disease from cancer is to recognize the acute onset and subsequent clinical course. In plasma-cell mastitis the initial picture is that of an acute or subacute inflammation which appears suddenly and subsides rapidly. The process regresses steadily, whereas in carcinoma the process is reversed. The disease begins locally and extends progressively. A single examination is generally inadequate, for only by several examinations can one determine whether the disease is progressing or regressing. This is the most important single factor in the differential diagnosis.

Plasma-cell mastitis has to be distinguished from (a) inflammatory carcinoma, (b) diffuse duct carcinoma, and (c) traumatic mastitis. The initial stages of plasma-cell mastitis resemble inflammatory carcinoma; in the latter state, however, the carcinomatous invasion of the subdermal lymphatics gives rise to an irregular ridge-like thickening of the skin which is not present in plasma-cell mastitis. Diffuse duct carcinoma complicated by inflammation may simulate plasma-cell mastitis, but the disease process is diametrically opposite in the two conditions, one being steadily regressive, the other steadily progressive. Traumatic mastitis is differentiated by the history of trauma and the classical transillumination findings.

There are two pitfalls in the microscopical interpretation, and both apply specially to the examination of frozen sections, in which the fixation is generally inadequate. The intense epithelial hyperplasia often appears to have invaded structures outside normal boundaries. Paraffin sections of the same areas show that the masses of cells are actually confined within normal boundaries of ducts and acini, yet the picture can be so confusing that errors are sometimes made by the most expert. Another source of confusion is that the plasma cells may be so large and oedematous that in frozen sections they resemble anaplastic malignant epithelial cells.

Prognosis and Treatment

This curious unexplained inflammatory process tends to spontaneous regression and resolution, although a remnant often remains for long time. The possibility that the disease may be precancerous has to be considered, but the clinical evidence is rather against this theory. I have observed one example which was suggestive of a relationship between plasma-cell mastitis and cancer. Adair points out that the time factor has to be considered, and it may well be that further observations will tend to establish a closer relationship between the two states.

The differential diagnosis between the early stages of plasma-cell mastitis and diffuse duct carcinoma with or without inflammatory signs is sometimes difficult. In order to avoid undue delay in establishing the diagnosis, it seems best to perform biopsy early. In former publications I was rather against biopsy during the early acute stage of the disease, but subsequent experience leads to the opinion that, generally speaking, less harm is done by a carefully performed but adequate biopsy than might be done by delaying a diagnosis of cancer. If the inflammatory process is definitely subsiding there would seem to be an advantage in postponing biopsy for a short period.

The safest treatment during the chronic stage, when the lesion is localized, is to remove the diseased area surgically. If most or all of the breast is involved and the inflammatory signs have disappeared simple mastectomy is indicated. During the acute and early subacute stages, the diagnosis having been established microscopically, irradiation should be given, with the reasonable expectation that the lesion will regress and become more localized. Surgical removal of the remnant can then be performed. The possibility that irradiation alone will suffice has to be considered, but until

more cases have been studied over long periods surgical removal, alone or combined with irradiation, constitutes the safest course to pursue.

Summary and Conclusions

Plasma-cell mastitis is a clinical pathological entity. It is a peculiar inflammatory condition of uncertain aetiology. Its practical importance lies in the fact that it simulates cancer so closely that in the past it has almost always been treated by radical mastectomy. Since the onset and the course of the disease are highly characteristic and unlike those of cancer, a distinction is generally not difficult if one keeps the possibility of this condition in mind and if one elicits a careful history in every case of suspected mammary cancer. As regards treatment, the safest course to pursue after establishing the diagnosis by adequate biopsy is surgical excision during the later stages, when the lesion is localized, and irradiation during the acute or subacute stages followed by conservative surgical excision of the remnant.

A case of plasma-cell mastitis with bilateral involvement is reported in which irradiation demonstrated the lesion to be highly radiosensitive. So far as I know, no example of bilateral involvement has hitherto been recorded under this title.

TWO COMMON NON-MALIGNANT CONDITIONS OF THE BREAST

THE CLINICAL FEATURES OF CYSTIC DISEASE AND THE PAIN SYNDROME

BY

DAVID H. PATEY, M.S., F.R.C.S.

Surgeon, Middlesex Hospital

The clinician tends to divide pathological conditions of the breast into two big groups: a group composed of well-defined pathological entities such as abscess, fibro-adenoma or carcinoma; and a vague, ill-defined group with varying and indefinite symptoms and signs which he tends to lump loosely together under some such title as chronic mastitis. Owing to confusion which sometimes exists about this latter group I have thought it worth while to describe the two common non-malignant conditions of the breast as I see them clinically. I have also reviewed the literature in broad perspective to show how some of the ideas on this group of disorders have arisen. I would like to support the plea of Cheate for the abolition of the term "chronic mastitis," which has lost almost all precision and value; its sole remaining virtue is that no one can agree on a term to replace it. Deaver and McFarland in 1918 were able to collect no fewer than 23 different terms, and many more have been added since. Rather than attempt to burden the literature with still further terminologies I have thought it

best to rely on a purely factual descriptive term for each of the two main varieties of disorder met with.

There are two common non-malignant conditions of the breast met with clinically. The first is a condition with objective clinical signs—*cystic disease of the breast*; the second is a subjective disorder, the one symptom common to all cases being pain, and therefore it is best labelled the *pain syndrome*.

Cystic Disease of the Breast

Cystic disease of the breast is most commonly met with clinically between the ages of 40 and 50; it may be seen in the late thirties or early fifties, but it is rare for it to develop much earlier or much later. Far and away the commonest clinical picture is that of the *apparently solitary cyst*. A woman without any pain or other premonitory symptoms suddenly happens to feel a lump in her breast. In some cases the patient feels convinced that the lump was not there a short time before, and that it came up suddenly.

On examination the breasts appear normal in all respects on inspection and palpation except for the presence of the lump—hard, smooth, rounded, and with a characteristic dome-shaped top—of a size usually between $\frac{1}{2}$ in. (1.9 cm.) and 2 in. (5 cm.). Elasticity and fluctuation are exceptional. There may be a faint suggestion of lobulation in the form of a slight groove, but not nearly of the degree met with in a fibro-adenoma. There is no skin dimpling, nor are there other infiltrative signs. The diagnosis is established by aspiration, when anything from 2 ml. to 20 ml. of watery fluid, greyish green by reflected light and reddish brown by transmitted light, is obtained. Following aspiration the lump completely disappears and the breast returns to normal, although in the case of large cysts for a day or two a hollow may be felt in the position of the cysts with condensation of the tissues around. The periods are usually regular and normal, there is nothing in the immediate clinical history to indicate the cause of the development of the cyst, and usually there is nothing of note in previous history or the family history. But it has been known since the days of Réclus and Schimmelbusch that the apparently solitary cyst is an expression of a diffuse condition of both breasts, and it is not surprising, therefore, that further cysts sometimes develop, either in the same or in the opposite breast, which lend themselves to aspiration in the same way as the original cyst.

A woman may not come for medical advice until she has in one or both breasts a number of large cysts similar to the usual solitary type—*multiple cysts*. She may come with clinically diagnosable *diffuse cystic disease* of both breasts—a comparatively rare form. The whole of each breast feels shotty and not unlike the normal physiological type of shotty breast, but differing in that the shotty nodules are larger and coarser, varying in size, and in some cases large enough to allow of the insertion of a small needle and the aspiration of fluid, thus confirming the cystic nature. And finally, forming the most difficult diagnostic problem of all, there is the condition of *small aggregated cysts*. This may occur in breasts that are otherwise normal clinically or in breasts affected with clinically diagnosable diffuse cystic disease. A lump an inch (2.5 cm.) or so in diameter is felt which is hard and irregular, just like a carcinoma but without skin dimpling or other infiltrative signs. The lump is formed by the aggregation of a number of small cysts, each of which may be so tiny that nothing may be obtained on aspiration, thus suggesting that it is a solid mass. The establishment of the diagnosis of this type is usually possible only after exploration and naked eye and microscopical examination.

The Pain Syndrome

The second common clinical group of non-malignant disorders of the breast is the subjective disorder which, as stated above, I think best called the *pain syndrome*, affecting women from the twenties onwards. There are no objective findings. The pain may be an exaggeration of the normal premenstrual feeling of engorgement and sensitiveness of the breasts, or may be present between the periods as well. In other cases it may bear no relation to menstruation. The pain may affect both breasts diffusely, one breast, or a part of one breast. Any form of breast may be affected. In many of these cases there is the phenomenon of the *pseudo-lump*—i.e., the suggestion of a lump which can be felt with one method of palpation but not with another. Sometimes it is the feeling of this pseudo-lump by the patient that leads to her seeking medical advice. One other and common feature of cases of this type is the fear of cancer, experienced before and sometimes after complaint of pain. This fear may have to be elicited by direct questioning.

Both cystic disease and the pain syndrome are the commonest non-malignant conditions of the breast, the pain syndrome being slightly commoner than cystic disease, and the two together about equal in frequency to malignant disease.

Historical Review

In most reviews of the literature priority is given to Astley Cooper (1829) for the first important description of cystic disease of the breast. Credit for the first coherent account of cystic disease is usually given to Brodie (1846), but my own impression of Brodie's writing is that he did not clearly distinguish between cystic disease and what we now know as Brodie's tumour (cystic or giant fibro-adenoma). A few years later Birkett (1850) and Velpeau (1856) published monographs on diseases of the breast in which both cystic disease and the pain syndrome are clearly recognized and their main clinical features described. James Paget (1870) was interested mainly in the morbid anatomy of the cysts, which he regarded as obstructive in origin and due to periductal fibrosis, comparing cystic breasts to granular kidneys. This almost certainly wrong view of the origin of cystic disease for long persisted in the literature in spite of the work of Réclus and Schimmelbusch, which showed that cysts were secondary to epithelial changes in the ducts of the breast, and has finally disappeared only with the experimental production of cystic disease by hormones. Bryant (1887) also separated the pain syndrome and cystic disease as distinct entities.

By the latter half of the last century surgeon pathologists had recognized and defined the clinical features of both cystic disease of the breast and the pain syndrome. But the position soon became more complicated with the development of the morbid histological era in the study of breast pathology, especially by Réclus and Schimmelbusch. Réclus wrote a number of papers between 1883 and 1893 on what he called cystic disease of the breast. His main contribution was to call attention to its diffuse and usually bilateral character, and to give a clear picture of its morbid anatomy and histology. To begin with, Réclus regarded the condition as precarcinomatous, and treatment by mastectomy or even bilateral mastectomy as obligatory, but as the result of clinical experience he ended by coming to the opposite view. Schimmelbusch (1892) clearly established the histological features of the disease. He showed that the formation of the cysts was determined by the proliferation of the glandular tissue of the mamma, and as a result suggested the term of "cyst adenoma." And he concluded that if there was any risk of carcinoma

developing it was too small to justify such a drastic procedure as bilateral mastectomy, which was the rational one if prophylactic surgery were to be adopted. König (1893) appears to have been the first to emphasize the commonness of the disease.

By drawing attention to the epithelial changes in cystic disease Réclus and Schimmelbusch unwittingly supported the view which already existed, that the disease was precarcinomatous and dangerous; as a result the advocacy and practice of mastectomy increased. Most authors, however, did not carry their logic so far as to advocate bilateral mastectomy. From their time, too, the practice of grouping together cystic disease and the pain syndrome as different phases of the same condition became more general. The classic monograph of Cheate and Cutler (1931), with its detailed study of the histological changes of cystic disease, was careful to point out once again that the pain syndrome which they called mazoplasia was a separate condition and not precarcinomatous. (Cheate and Cutler's work was also noteworthy for pointing out authoritatively that nodularity of the breasts is not necessarily pathological; it occurs regularly under physiological conditions such as menstruation and may result from change in the supporting fat of the breast.) Among the latest writers who under the influence of histological appearances regard cystic disease of the breast as precarcinomatous is Willis (1948). But the clinical evidence to the contrary has always been very strong. I previously reviewed this question in 1939, and would refer readers to this review and to Geschickter's (1943) monograph for further references. But to take the most important observations, Bloodgood (1931), who throughout the early part of the century wrote many papers on the subject, reported a follow-up for periods of up to 30 years of more than 100 patients from whom blue-domed cysts had been removed, and found none had developed cancer. Campbell (1934) refers to 233 cases of "chronic mastitis" treated by local excision of areas of breast tissue and followed up for from 2 to 14 years. In one patient only did carcinoma of the breast develop. Geschickter found no cases of carcinoma in 231 cases of the pain syndrome followed up for many years, and only four cases of carcinoma in 378 cases of cystic disease. It is not surprising, therefore, that for many years now clinicians have tended to conservatism in the treatment of both cystic disease and the pain syndrome, and that mastectomy is rarely performed for these conditions, and still more rarely the only logical prophylactic procedure—bilateral mastectomy.

From 1930 onwards many investigators have shown that a cystic disease may be produced in the breasts of animals, chiefly mice and rats, by large doses of oestrogenic substances and that under certain conditions carcinoma of the breast may supervene (see review; Patey, 1939). Geschickter (1943) has more recently summarized his own extensive personal experimental work as well as reviewing the literature. But the application of this experimental work to human cystic disease is not clear in the field of aetiology or of treatment. Thus Bucher and Geschickter (1941) say, "It is not possible to state with assurance the endocrine disturbance in cystic disease,"—i.e., human cystic disease. And Taylor (1942) notes, "In spite of much discussion of chronic mastitis as an endocrine disease, no one has yet succeeded in proving that this breast condition represents a specific response to any recognized type of glandular dysfunction." And it is a matter of common observation that neither in cystic disease nor in the pain syndrome is there any undue frequency of menstrual disturbance. While Spence (1940) thought that testosterone injections and inunctions helped the symptoms of the pain

syndrome, he had improvement in some cases from the inunction of bland ointments; and Atkins (1940) and Taylor (1942) are among those who have found hormonal treatment of this group of disorders of little practical value.

Discussion

Three important questions arise: Are the conditions both manifestations of the same disorder, or are they two separate disorders? What is their cause, or causes? What relation, if any, have they to carcinoma?

As to the first question, there is such a striking clinical difference between the patient with a cyst and the patient with the pain syndrome whose breasts show no clear objective features to distinguish them from any normal woman's that the clinician can only answer that they are separate conditions.

Under the second question, therefore, we have to consider two questions—What is the cause of cystic disease? and What is the cause of the pain syndrome? The fact that cystic disease predominantly affects women of between 40 and 50 suggested to clinicians long ago that it was related to the hormonal changes occurring at that time, and Deaver and McFarland had suggested that they should be termed "involution cysts." But hormonal disorder is still a hypothesis although supported to some extent by experimental work. The pain syndrome, being a subjective disorder, is most likely to have a subjective cause, and here at once the most striking feature is fear of cancer. In many cases the fear of cancer is clearly the origin of the whole trouble. In other cases, but less frequently, the fixation on the breast is determined by an injury or some previous disease of the breast. But in a small proportion of cases the origin may be psychosexual. Quite accidentally in one of my cases a patient raised the question whether it might be due to a sexual maladjustment with her husband. And since then I have come across a number of similar cases—e.g., the young married woman who wants children while her husband does not; the woman married to a husband much less passionate than herself; and cases with difficulties in the sexual act. I have never regarded it as within the province of the surgeon to make routine inquiries into the sexual life of patients who come with breast troubles. And in those cases of the pain syndrome which I cannot explain on the usual fear-of-cancer basis I tell the patient that some cases of pain in the breast are due to sexual maladjustment or anxieties. Some patients will then wish to discuss further possible factors on these lines; others will not. In any case the bringing of this explanation into the open will often have a beneficial effect. Any deeper exploration of the psychosexual upset is the concern of the psychiatrist rather than the surgeon. At the present time it is not possible to say whether psychosexual factors act on the breast through nervous or through hormonal influences. It is possible that both factors are involved.

Finally, we must attempt to answer the question, What is the relation, if any, of these disorders of the breast to cancer? The pain syndrome, being a functional condition without organic basis, must clearly be quite unrelated to carcinoma. The views of various authorities on cystic disease have already been given. But the strongest support for the now predominantly held clinical view that cystic disease is not a dangerous condition likely to develop into carcinoma is the experience of many surgeons all over the world who for years have treated the condition by some simple procedure such as tapping, with its demonstration that these conservatively treated breasts do not show any special liability to develop carcinoma.

Summary

Chronic mastitis is a term which has lost all precision and value and should be abolished. There are two common non-malignant conditions of the breast met with clinically—cystic disease and the pain syndrome—which are separate and distinct conditions. Cystic disease presents clear objective physical signs from which a clinical diagnosis can be made, the cause is unknown but is possibly a hormonal upset, there is no special liability to carcinoma of the breasts affected, and tapping is a satisfactory treatment. The pain syndrome is a purely subjective disorder, although sometimes superimposed on exaggerated physiological premenstrual engorgement of the breasts, and the breasts affected present no objective abnormality. The cause of the fixation on the breast is usually fear of carcinoma, but in a small proportion of cases is a psychosexual upset. Treatment by explanation and reassurance usually results in cure of the pain.

AMETHOCAINE HYDROCHLORIDE

SEVERE TOXIC EFFECTS WHEN USED FOR BRONCHOSCOPY

BY

C. A. JACKSON, F.R.C.S.

Chief Assistant, St. Bartholomew's Hospital Chest Unit.
 Hill End Hospital and Clinic, St. Albans

Amethocaine hydrochloride is increasing in popularity in this country as a surface analgesic. The occurrence of two severe toxic reactions arising from its use in a thoracic unit while securing analgesia for bronchoscopy has emphasized again the danger of overdosage when applied to a mucous surface, together with a specific sensitivity shown by certain individuals. These near tragedies have prompted me to review similar cases reported in the literature and to study the properties of this drug. Since amethocaine has been used for surface analgesia twelve deaths at bronchoscopy and gastroscopy have been reported by various authors and a further three deaths during preparation for urethral instrumentation.

Whether it be due to sensitivity or overdosage, the nature of the reaction reveals a striking similarity in the majority of cases and is the typical classic picture of cocaine or procaine intoxication. Within a few moments of local application the patient becomes faint and giddy, and unconsciousness follows. There may be wandering or deviation of the eyes. A trembling and twitching of the extremities occurs

which rapidly develops into generalized clonic convulsions, epileptiform in nature, during which cyanosis, foaming at the mouth, and an accelerated weakened pulse are noted. This seizure may subside with recovery or may return with a greater violence, when the patient may succumb from respiratory or cardiac failure.

Cases in the Literature

There have been a number of case reports in German and American journals since 1935 giving instances of severe constitutional disturbances and even fatalities. Apart from two deaths recorded by Hancock (1939), the only British report is found in a statistical review of causes of sudden death in which two fatalities are recorded as having occurred when this analgesic was being used in bronchoscopy.

In 1939 Fasselt reported two reactions to amethocaine 2% in anaesthetizing the throat before the removal of foreign bodies by bronchoscopy. All symptoms, however, disappeared spontaneously in these cases. Phillips and his associates (1941) reported a similar reaction in a patient who was undergoing a bronchoscopic examination. In this case generalized tonic contractions occurred which were controlled by "dial," 2 ml., given intramuscularly; the strength of the solution was not mentioned. The patient recovered.

Schoen (1939) reported three fatal reactions to local analgesia using amethocaine prior to bronchoscopy. Wagener is reported by him to have quoted a case in which 6 ml. of 2.5% solution was applied to the larynx for the removal of a wart and in which general convulsions occurred, leading to death in six to eight minutes.

In a case quoted by Cazzaniga (Schoen, 1939) a total dose of less than 130 mg. of amethocaine was used, yet the patient, a 27-year-old woman with pulmonary tuberculosis, developed severe convulsions some seconds after the initial administration and death occurred thirty minutes later.

Freeman (1939) reported four serious accidents with amethocaine employed as a mucous membrane analgesic for gastroscopy. Hancock (1939) had two deaths from the drug, also used for gastroscopy. His patients were both in advanced cachexia from malignant disease of the stomach.

Pfeiffer (1937) and Shumacher (1941) reported sensitivity to 0.5 and 1% solutions when administered in the eye. Videbeck (1936) mentioned three cases of amethocaine eczema in doctors who used the drug in their practices.

Thomas and Fenton (1943) provide a series of cases of their own in which amethocaine was shown to possess definite toxic properties. The first patient gave a history of asthma but no history of drug sensitivity. During bronchoscopy, while receiving a second spray of amethocaine 2% five minutes after the first, he had a sudden severe asthmatic attack and died thirty minutes later. A woman giving a history of pulmonary tuberculosis of one year's duration and with no known allergy, after receiving 5 ml. of amethocaine solution by pharyngeal spray became faint and suffered a generalized convulsive seizure with frothing at the mouth, which persisted until respirations ceased. Two other patients, both women, underwent bronchoscopy with amethocaine local analgesia for investigation of bronchiectasis. Feeble respirations, cyanosis, weak pulse, and clonic convulsions developed in both patients. Only after the administration of adrenaline and oxygen did these patients return to consciousness. In both cases skin tests for amethocaine sensitivity proved positive when performed afterwards. A 58-year-old man, after a gastric resection for carcinoma, was being prepared for gastroscopy with a 2% amethocaine gargle, to be followed by a 5-ml. spray, this to be repeated

in ten minutes. About fifteen minutes later the patient became stuporous, suffering clonic convulsions involving the arms and legs, lacrimated, and there was drooling of saliva and grinding of the teeth. The skin was cold and clammy, the lips were cyanotic. This reaction lasted ten minutes, but the patient recovered. One patient, ten minutes after receiving 5 ml. of 2% amethocaine prior to gastroscopy, became pulseless and convulsive, developed jerky respirations, and died. Three other cases were marked by nystagmus and convulsive seizures, but all three patients survived.

Doane and Cohn (1945) reported the case of a 48-year-old woman who suffered severely from asthma. Sixteen days before admission under their care a successful bronchoscopy had been performed, using 2% amethocaine as a spray. Five days after admission she was being prepared for a bronchogram; 2 ml. of a 2% solution were instilled by a nasal catheter, no premedication being given. A further 1 ml. of the solution was being instilled eight minutes later, when the patient slumped forward unconscious and in another three minutes slight convulsive movements occurred. This seizure was relieved by 2 g. of sodium phenobarbitone intravenously, but soon returned with greater violence. A double dose of barbiturate and cardiac restorative measures failed and the patient died thirty minutes later.

Richards (1947) recorded two cases of sudden death following the application of a 2% amethocaine spray for the purpose of bronchoscopy—one in a patient with a lung tumour and the other in a case of bronchiectasis. In both cases generalized convulsions set in within a few minutes and death occurred very shortly afterwards.

Shindler (1940) and Holt (1945) each report a fatality.

Properties of the Drug

Amethocaine, known variously as "pantocaine," "ponto-caine," "anethaine," "dikaine," "tetracaine," and "decicain," belongs like procaine to the para-aminobenzoyl group of anaesthetics and was introduced as decicain about eighteen years ago by Bayers.

Advantages.—It is resistant to boiling, it is stable in solution, it is lethal to all non-sporing organisms, it is ten times more potent than procaine or cocaine, and it is relatively quick in achieving its action and provides prolonged analgesia. Although the onset of analgesia is slower than with cocaine, the effect is more persistent.

Disadvantages.—It penetrates the tissues more rapidly than procaine and does not produce the vasoconstrictive action of cocaine. It is therefore essential to use it in conjunction with adrenaline, which reduces its toxicity by one-fifth. The relative toxicity of amethocaine, cocaine, and procaine is 4.5, 3, and 1 respectively, but this disadvantage is mitigated by the effective dose being one-tenth that of cocaine. It is detoxicated more slowly than procaine. It is less soluble than procaine 1 : 7 to 1 : 1.

For injection 0.1 and 0.05% solutions are recommended. For surface analgesia 2% solutions are advised (James, 1943). In Cazzaniga's case death occurred with a dose of 130 mg.; but James has used as much as 300 mg., although he advises that this amount should never be exceeded. The recommended therapeutic dose in man is 2 mg. per lb. of body weight. Hancock (1939) refers to a series of 2,000 cases of gastroscopy performed using 10 ml. of 2% solution without mishap.

For four months we have given anethaine, a 2% solution of amethocaine hydrochloride (4 ml. in conjunction with 1 ml. of 1 in 1,000 adrenaline), preparatory to bronchography and bronchoscopy. For the latter investigation the following was the procedure adopted.

The patient is given two "euphagin" tablets (benzocaine 200 mg.) to suck forty minutes pre-operatively, followed ten minutes later with $\frac{1}{4}$ or $\frac{1}{2}$ gr. (11 or 16 mg.) of morphine. In the anaesthetic room the fauces, posterior pharyngeal wall, and both pyriform fossae are painted with the above solution, using about 2 ml., but only a portion of this amount would actually be expended. A final injection of 2 ml. between the cords under direct vision usually effects adequate analgesia for the examination, although a further supply of the local analgesic is available for direct bronchial spray if required.

Case Reports

Case 1.—The patient was a 62-year-old man with superior mediastinal obstruction believed to be secondary to a right upper lobe bronchial carcinoma. Local analgesia for bronchoscopy was being induced by the above method with 5 ml. of mixed solution. Within 30 seconds of the intratracheal injection the patient, who was sitting up, complained of giddiness and then fell back unconscious; convulsions followed as described above. Endotracheal oxygen and carbon dioxide was instituted immediately. The head was lowered and venepuncture performed, 500 ml. of blood being withdrawn. Recovery took place after three convulsive seizures. There were no sequelae.

Case 2.—A young man aged 21 with left lower lobe bronchiectasis was having preparation of the pharynx and larynx by this method, but 4 ml. of the solution instead of the usual 2 ml. was injected between the cords. (The first 2 ml. was thought to have been swallowed.) Within a few moments the patient became pale and a cold sweat broke out on the face; he lay down and at once started jactitating, at first in the lips and then in the limbs. The pulse was 80-90, regular and of good volume. He then had a convulsion, during which he became cyanosed. The clonic spasm subsided and respirations returned, but were shallow and rapid. Almost immediately convulsions were renewed with increased intensity. The patient became deeply cyanosed, and during the clonic stage it was noticed that the pulse had ceased. Intracardiac adrenaline 2 ml., was injected, while artificial respiration was begun and oxygen was administered through a face-mask. There being no response to these measures, the abdomen was opened through an upper midline incision and direct cardiac massage through the diaphragm was performed. A flaccid immobile heart was massaged without response for about one minute. A few rhythmic contractions occurred, ceased, and then in response to further massage recurred. The heart subsequently started and continued to beat strongly with occasional extrasystoles. Although the total period of cardiac arrest was estimated at more than four minutes and unconsciousness persisted for four days, complete recovery took place.

Comment

The first patient was seriously ill with gross congestion of the head, neck, and shoulder girdle. He proved difficult to anaesthetize and was uncooperative. Five millilitres of the normal mixture (80 mg.) of amethocaine was used and must have been rapidly absorbed. The second patient was a relatively fit young man. In this case 4 ml. (64 mg.) of amethocaine mixture was projected between the cords into the trachea. In an endeavour to co-operate the patient was hyperventilating, so that the full quantity of this drug may have directly reached the alveoli and been rapidly absorbed from this highly vascular surface.

Neither patient gave a history of allergy, and, although in each case more than the usual 4 ml. of amethocaine-adrenaline mixture was used, both patients would appear to have been unusually sensitive to the drug.

No satisfactory sensitivity test has been described, but Thomas and Fenton (1943) recommended the use of a patch skin test in suspected or doubtful cases. They admit that such a test is not entirely reliable. They also suggest that

sensitivity to the drug may be provoked by its previous use or the use of procaine, which is closely related to it.

Certainly in two fatal cases (Ahroon, 1946; Doane and Cohn, 1945) there had been recent previous administration of the drug. Thomas and Fenton draw attention to the intolerance to amethocaine manifested by allergic individuals, bronchial asthmatics, etc., as well as by cachectic patients.

Following the method of Hancock (1939), the technique in preparation for bronchoscopy has been modified. Each patient is now given a 1-gr. (65-mg.) amethocaine pastille to suck thirty minutes before instrumentation. This produces a much more complete analgesia of the mouth and pharynx than benzocaine, and it is considered that any idiosyncrasy possessed by the patient would be displayed while the relatively small dose contained in the pastille was being absorbed.

Apart from the severe constitutional reactions to amethocaine on record other less serious reactions have been recognized. These include attacks of dyspnoea and asthmatic symptoms (Fujikawa, Neves, Brasher, and Buckingham, 1948), blepharoconjunctivitis (McAlpine and Berens, 1942), and occupational dermatitis and eczema in doctors and oculists (Videbeck, 1936; Cameron, 1937; Hollander, 1939; Shimkin, 1939).

Prevention of Severe Reactions.—The following prophylactic measures are suggested: (a) A barbiturate should be given by mouth in pre-operative preparation—e.g., phenobarbitone 3 gr. (0.2 g.) or sodium amytal or nembutal 1½ gr. (0.1 g.) 40 minutes before examination. (b) An amethocaine pastille, 1 gr. (65 mg.), should be given to the patient to suck 30 minutes before the examination. (c) Amethocaine when used for surface analgesia should have adrenaline 1 in 1,000 solution added in the proportion of 4 to 1 by volume, and the total dose of amethocaine should not exceed 4 ml. of a 2% solution (80 mg.) or a corresponding amount in a more dilute solution. (d) Application by means of a laryngeal spray should be avoided, since its use can easily lead to overdosage. (e) Amethocaine should never be applied to an inflamed, traumatized, or highly vascular epithelial surface—especially so in the urethra (Knepper, 1937). (f) The drug should be avoided in patients giving a history of allergy or in severely debilitated or cachectic cases.

Control of the Established Reaction.—(i) General:—Secure an unobstructed airway by endotracheal tube if necessary. Begin artificial respiration with an oxygen-carbon-dioxide mixture. (ii) To control convulsions:—The immediate intravenous administration of a rapidly acting barbiturate—20 ml. of 2½% sodium thiopentone (0.5 g.)—is usually sufficient to control convulsions. (Picrotoxin should be available in case too much barbiturate is given.) (iii) Administration of respiratory and cardiac stimulants:—nikethamide, 2–5 ml.; caffeine sodium benzoate, 7½ gr. (0.5 g.), etc.

In using amethocaine in surface analgesia, as with many other local analgesics, from time to time the unusually susceptible individual may be met with. Reactions come with devastating suddenness and the results may be disastrous. By excluding those patients mentioned under (e) and (f) above, sensitive patients should be even more rarely met with. An analysis of the fatal cases reported reveals overdosage, faulty technique, or failure to use adrenaline to be more often the cause of death than individual idiosyncrasy.

Summary

A report is given of two toxic reactions with the use of amethocaine hydrochloride as an analgesic for bronchoscopy.

A review of the literature reveals twelve reported deaths at bronchoscopy and gastroscopy, while there are many cases of severe constitutional disturbance.

The advantages and disadvantages of the drug are assessed, the difficulty of applying an adequate sensitivity test accepted, and suggestions made for the prevention and treatment of toxic reactions.

I wish to express my thanks to Mr. O. S. Tubbs for permission to report these cases and for helpful advice in the preparation of this paper.

"GAMMEXANE" AND MOSQUITO CONTROL IN THE BELGIAN CONGO*

BY

G. DAVIDSON, B.Sc.

(From the Ross Institute of Tropical Hygiene)

Experiments are now being carried out in a large palm-oil plantation at Yaligimba, in the Belgian Congo, on the control of malaria by adult mosquito destruction, using the residual insecticide "gammexane" in the houses in the labour camps and in several native villages around the plantation. The plantation, which occupies an area of some 30 square miles (77.7 km.²), is situated in a forest belt in the northern part of the Belgian Congo. The main species of anopheline mosquito concerned is *A. moucheti*, which breeds at the edges of the large rivers in the vicinity. There are also a few *A. gambiae* and *A. paludis*.

Mosquito densities in the houses before and after treatment with the insecticide are being determined by the following four methods:

1. The number of mosquitoes resting in the houses during the daytime is being estimated by laying white sheets over the whole floor surface of a house and spraying the closed house with a pyrethrum-in-kerosene spray.
2. The number of mosquitoes leaving the house each morning is being determined by the use of window-traps.
3. The number of mosquitoes entering during the night to bite the occupants of any one bed in the house is being determined by the use of mosquito-net traps, which mosquitoes can enter but not leave.
4. The mosquito-nets of the inhabitants of the camps and villages are being examined to determine the percentage

*This work has been made possible by grants from United Africa Company, Limited, and from Imperial Chemical Industries, Limited.

containing mosquitoes. The majority of these nets are made of calico and are usually incompletely closed by the occupant or in a bad state of repair.

Parasite rates and spleen rates have been estimated among children in many of the camps and villages before treatment, and are high throughout the area. These will again be estimated in both treated and untreated villages one year after treatment, as will the parasite rate among babies born in the villages during that year.

Salivary gland dissections are also being done on the mosquitoes before and after treatment. The sporozoite rate in the main anopheline, *A. moucheti*, is naturally low—0.4% in 3,712 dissections—and large numbers of dissections have had to be done.

Water-dispersible powders containing gammexane have been used for the spraying of the internal surfaces of the houses, and a concentration of 10 mg. of gammexane per square foot (930 cm.²) of surface has been aimed at. Eclipse "Warley" pneumatic sprayers of 2 gallons (9 litres) capacity are being employed for the spraying. These give an application rate of approximately 5 pints (2.84 litres) of spray per 1,000 square feet (93 m.²) of surface.

Results so far show after treatment a very marked reduction in the numbers of mosquitoes caught by the four methods outlined above. The best results have been obtained with the water-dispersible powder P530, containing 6% of gammexane. Mosquitoes caught by the window-trap method began to appear in significant numbers in the fifteenth and sixteenth weeks after treatment. Mosquitoes caught by the net-trap method were showing only a slight increase at this time, and almost no mosquitoes were found by the other two methods. The unreliability of estimating the persistence of the insecticide by determining mosquito densities by the flit-catching method alone has been clearly demonstrated.

Results of salivary gland dissections from treated and untreated villages are:

	Dissected	Positive	Percentage
Untreated villages:			
<i>A. moucheti</i> ..	3,712	15	0.40
<i>A. gambiae</i> ..	408	17	4.17
<i>A. paludis</i> ..	45	0	0
Treated villages:			
<i>A. moucheti</i> ..	2,001	1	0.05
<i>A. gambiae</i> ..	44	0	0
<i>A. paludis</i> ..	12	0	0

The only positive *moucheti* mosquito from a treated village was found in a net-trap three weeks after the first treatment of the village, at a time when another village only 2 kilometres away remained untreated. It is therefore possible that this mosquito flew from the untreated village and entered the net-trap without coming into contact with the treated surface of the house.

The site for these experiments was originally chosen with a view to possibly eradicating the mosquitoes in the plantation solely by adult mosquito destruction in houses. It was soon decided, however, that the plantation was not sufficiently isolated for this to be achieved, and the reappearance of mosquitoes in significant numbers after the treatment of single villages or groups of villages, isolated to the extent of 3 to 4 kilometres, has confirmed this view. However, it is proposed to try to eradicate the mosquitoes in the plantation by spraying also the villages which lie near to the plantation to form a protective barrier against invasion of mosquitoes into the treated plantation. It is thought that an initial spraying of the whole area three times during the first year can be reduced to twice a year and be quite an economical proposition.

It is hoped to publish shortly a more detailed account of this work.

Medical Memoranda

Twisted Ovarian Cysts in Children

Ovarian cyst with torsion of the pedicle is an uncommon condition in children, only about 125 cases having been reported in the past hundred years. The literature contains such interesting cases as an ovarian cyst in a 7-months premature infant and torsion of an ovarian cyst in a 10-days-old baby (Bursch). The majority of twisted ovarian cysts in children occur on the right side, and because of this the diagnosis made is usually that of acute appendicitis, or appendicular abscess if a mass is palpable. There may be symptoms of a vague character consisting of nausea and vomiting, preceded by vague abdominal ache for a few days, with one or more severe attacks of sudden abdominal pain lasting for a few hours, this being due to a tighter twist of the pedicle. The following reports illustrate typical cases.

CASE HISTORIES

(1) The patient, a girl aged 10, was first seen at 9 p.m. on Jan. 5, 1948. She had had a dull pain in the right side of her abdomen and right lumbar region on and off for three weeks, but 48 hours before admission she had had nausea and vomiting with increased pain in the right loin. Since then she had vomited white frothy matter. The pain remained in the back and right side of her abdomen and was at no time central. She had been constipated for some weeks, and 24 hours before admission had been given a soap enema, which yielded a very good result. She had had no urinary symptoms. Her activities were normal for her age, and she had been sleeping well.

On admission the temperature was 98° F. (36.7° C.), pulse 122, and respirations 24. She was a thin, pallid child; her tongue was slightly furred, with halitosis present. There was a moderate degree of rigidity in the right lower quadrant, with tenderness in the right side of the abdomen and right lumbar region, most pronounced about 1 in. (2.5 cm.) below McBurney's point. Rectal examination had been carried out, and the only thing noted was the presence of hard faecal masses. A diagnosis of acute appendicitis was made and laparotomy was carried out.

A Rutherford Morison incision was first employed and a plum-coloured mass was seen in the pelvis. Through this incision it was not possible to observe whether the mass was adherent to gut or not, and so a right subumbilical paramedian incision was carried out, when the mass proved to be a twisted right ovarian cyst, the size and shape of a kidney, with four twists in the pedicle. The pedicle was untwisted and afterwards transfixed, the cyst being then removed. The right tube was left intact. A small cyst was present in the left ovary. Both incisions were closed without drainage. Recovery was uneventful and the patient was discharged from hospital ten days after operation.

The histological report stated that there was massive haemorrhage in the cyst, in which were seen scattered capillaries, veins, and arterioles. Collections of polymorphs were present round most of the larger vessels, often with necrosis of the vessel wall. There was nothing to identify the tissue with certainty, but it was probably a connective-tissue tumour and possibly ovarian in origin. I am indebted to Dr. A. J. McCall for the histological report.

(2) On Dec. 5 a girl aged 9 years was admitted to hospital with the diagnosis of subacute intestinal obstruction. A cystic mass was felt on rectal examination. In the light of the experience gained in the case described above a diagnosis of twisted ovarian cyst was made. Laparotomy confirmed the diagnosis. A twisted ovarian cyst with four torsions of the pedicle was found on the left side. The cyst was removed as in the former case.

G. GORDON CROWE, F.R.C.S.Ed.,
Surgeon, City General Hospital, Stoke-on-Trent.

BIBLIOGRAPHY

Fowle, J. A. (1944). *Amer. J. Surg.*, 64, 285.

Precautions that the practitioner must take in dealing with drugs under the Dangerous Drugs Acts and Regulations are described in a memorandum "Dangerous Drugs Acts, 1920 to 1932," D.D.101, 5th edition (H.M.S.O., 3d.). Drugs covered by these Acts and regulations are listed, and the pamphlet describes how prescriptions for them must be written, dated, and signed, how the medical practitioner should obtain and store the drugs, and what records he should keep. The memorandum concludes with an appendix extracted from the Report of the Departmental Committee on Morphine and Heroin Addiction, discussing the precautions to be observed when administering these drugs in medical practice.

Reviews

SOCIAL MEDICINE

Changing Disciplines. By John A. Ryle, M.D. Lectures on the History, Method, and Motives of Social Pathology. Oxford Medical Publications. (Pp. 124; illustrated. 12s. 6d.) London: Oxford University Press (Geoffrey Cumberlege). 1948.

Because of the personal and professional stature of its author, and also because he was the first among us to assume the academic title of professor of social medicine, his views on the content, scope, instruments, and aims of this branch of medicine must necessarily command widespread attention. It is largely because of his personal qualities, the attractiveness of his advocacy, and the work that he performed while he was alone in academic social medicine that the subject has in Britain claimed such interest and that chairs of social medicine have been created and are now being filled in so many of our universities. It was fortunate, therefore, that Professor Ryle should have been persuaded to go to America and been required during the course of his visit to state his creed. As he says in his preface, in preparation for the visit he attempted to crystallize some of his ideas born of experience which had come to him since he had transferred his energies from the field of clinical and personal medicine to new ventures in the field of social medicine, from studies in individual pathology to studies in social pathology.

Professor Ryle senses that medicine is changing as social aims are changing, and he expresses the view that while medicine, through scientific and technical advances, has greatly gained in potentiality during the last quarter of a century it has become less surely attuned to some of the more fundamental human needs, to the deeper personal needs of the individual and to the broader social needs of the group or community. He charges the profession with thinking more about curing than preventing, more about medical care and its huge costs than about the economies that could be effected by attacking the basic causes of disease. His creed is stated. The whole man and his family are the practising physician's charge, but they can no longer be considered in detachment from their total environment or from the larger communities of which they are but a part. Communities large and small are now due for a more intimate study and care in respect of their health and sickness, for they cannot be considered apart from their total environment or from the individuals and families of which they are composed. State medicine must be based on scientific principles and especially on humane understanding. Good social medicine must in fact have its foundations in sound social pathology.

This book in the main is an edited collection of lectures previously given. The author discusses social pathology and the new age in medicine, the social post-mortem examination and its bearing on aetiological research, the affairs of the Institute of Social Medicine at Oxford, the meaning of normal and the measurement of health, social medicine and the population problem, medical ethics, and the new humanism, and he successfully answers the question how medicine in its immediate development may become better able to tackle the new problems that social changes have created, and how it may accept greatly enlarged responsibilities in relation to community health. It is much more than an intelligent discussion of matters of fact and of interpretation, for within its pages and behind the writing can be seen clearly the portrait of a man who in type and temperament is admirably suited for leadership in this particular field and whom the practice of humanitarian medicine has moulded into an altogether attractive person.

F. A. E. CREW.

HOUSING AND POPULATION

Housing and the Family. By M. J. Elsas. (Pp. 136. 8s. 6d.) London: Meridian Books Ltd.

This book is about the housing needs of the country in relation to the change in population consequent upon the declining birth rate and the trend towards a greater proportion of old

people. The author describes this relationship as "the demographic factor," and he discusses housing from the demographic point of view. There is a considerable amount of statistical information on the number and ages of existing houses, and information gained from a comprehensive questionnaire which was completed, at the author's request, by 18 local authorities—ten county boroughs, four boroughs, one urban district, and three rural districts. The questionnaire showed the number of dwellings built by the authorities concerned between 1919 and 1940, and the size, type, rent, etc., of each.

In Chapter V, "Housing Indices," it is interesting to note that there were in 1939 a greater number of dwellings per 100 persons than in 1931 (28.0 as compared with 23.5). Overcrowding was reduced, but the author points out that the improvement is not so great as might at first appear, since families are now smaller and more houses are required to accommodate the same number of people. He rightly criticizes the overcrowding standard as laid down in the Housing Act, 1936, as being too low (although the highest in Europe), but few public health officers will agree that a cubic-space instead of a floor-space standard is desirable. The cubic-space idea was rejected years ago, since it gave an altogether false value to the older house with 12-ft. ceilings, the upper 3 ft. at least performing no useful function. On such a standard a cathedral could accommodate more people than could stand in it. The present tendency to favour a ceiling of 8 ft. 6 in. has much in its favour from the public health point of view. The author's statement about overcrowding (p. 96), "Every room in the house can be used as a bedroom if it has sufficient space," may be misleading. In computing the permitted number of people for a dwelling-house, any room of a type not normally used in the locality as a living-room or bedroom is excluded. Thus sculleries and bathrooms are ignored, and in the ordinary working-class house—the "two up and two down"—the permitted number is generally five persons, for the back room downstairs is not generally used as a living-room.

The author criticizes the scarcity of rent rebate schemes and suggests a national rent rebate system to apply to all houses, whether owned by local authorities or private landlords. This is a highly controversial topic. The book is very interesting and can confidently be recommended to all concerned with housing or indeed the welfare of the people.

J. M. MACKINTOSH.

CHEMOTHERAPY IN MENINGITIS

Traitement Moderne des Méningites purulentes aiguës. By René Martin and Bernard Sureau. (Pp. 256; 40 figures, 2 plates. 450 fr.) Paris: Editions Médicales Flammarion. 1948.

The treatment and prognosis of meningitis have been changed by the discoveries of the past fourteen years more profoundly than those of any other disease. Most accounts of what chemotherapy can achieve deal either with a single type of infection or a particular form of treatment and are often based on relatively few cases. A treatise on the treatment of purulent meningitis in general, founded on the exceptional experience afforded by the Hôpital Pasteur in Paris, is therefore particularly welcome. The authors describe over 60 personal cases, many in detail; 28 of them were meningococcal, 13 pneumococcal, 6 streptococcal, 10 staphylococcal, and 4 due to *H. influenzae*. Except for the first-named infection, which usually responds well to sulphonamides alone, Martin and Sureau advocate combined antibiotic and sulphonamide treatment. Their methods are vigorous: intrathecal penicillin is given twice daily, and their dosage of sulphonamides is, if necessary, enormous, even reaching 1 g. daily per kg. body weight, and producing in the cerebrospinal fluid concentrations up to 70 mg. per 100 ml. Sulphadiazine is favoured, and another sulphonamide is often given together with it. The reader perplexed by the French designations for these drugs (sulphanilamide, for instance, being "1162F") will find a key to them on page 132.

After accounts of the treatment of each form of meningitis, based on the literature as well as the authors' own experience, there are chapters on the agents and methods used, on relapses and their distinction from effects of the treatment itself ("medicamentous meningitis"), on recurrent meningitis in cases of congenital cerebrospinal rhinorrhoea and its surgical

prevention, and finally on laboratory aids to the direction of treatment, the necessity of which is strongly emphasized. The authors provide an extensive classified bibliography, which includes references to papers on meningitis caused by no less than 17 species other than the common ones already mentioned. This monograph contains a mass of information of great practical value, and will be read appreciatively by everyone interested in its subject.

L. P. GARROD.

PRIVATE AND STATE MEDICINE

Private Enterprise or Government in Medicine. By Louis Hope-well Bauer, A.B., M.D., F.A.C.P. (Pp. 201. 25s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications.

The title of this book makes an instant appeal to members of a profession which in Britain has been trying to solve the problem raised since the publication of the Report of the Royal Commission on the Poor Law in 1909. Here, as in the U.S.A., it is a fact that a considerable section of the population is unable to pay for complete medical care by private fees. Here, as in all democratic countries, our profession would agree with Abraham Lincoln's dictum quoted on the jacket of Dr. Bauer's book, "In all that the people can individually do as well for themselves, the Government should not interfere." But how shall we find some method of supplying what is needed short of compulsory insurance or socialization of medicine? There is no answer to this yet. Since the end of the first world war the medical profession in the U.S.A. has been fighting attempts to increase Government control, and on the whole successfully. Of these proposals Dr. Bauer gives full details. It is evident that the fight is still on. The book makes no pretence of being impartial. My criticism is that the author makes no attempt to show that there is another side to the argument, and exception can fairly be taken to the biased and exaggerated accounts given of the effects of compulsory sickness insurance in those countries which have tried it.

In his anxiety to show that there is no need for other than voluntary effort in the States Dr. Bauer says that "the proportion of medical men to population is greater here, that no other country has obtained a better distribution of doctors in the rural areas, and that preventive medicine is more effective in the U.S.A. than in countries with compulsory insurance." Yet the book contains much evidence that the rural distribution is deplorable, and Dr. Bauer has apparently never heard of our Highlands and Islands scheme. On one page he tells us that in half the counties of the States there are no whole-time medical officers of health and in some of them there is no continuity of service and they are subject to political control. The British system of N.H.I., he says, "encourage mass therapy, and medication is controlled by the Government," and "it is often stated that the British system is far better than the system which prevailed before 1911. This is undoubtedly true, because the system then in vogue [which by the way was private enterprise] was so intolerably bad that any change was bound to be an improvement." This is only one, but a typical, example of the author's judgment of the conditions in other countries, and it is in my opinion sufficient to justify one who knows better in being cautious in accepting his conclusions.

Dr. Bauer frankly recognizes the existence in the U.S.A. of large sections of the people who are either "indigent" or "medically indigent" and that it is up to the medical profession to find a way to satisfy their needs. He strongly advocates voluntary local schemes, and shows that already many such schemes favoured by the A.M.A. are in operation. The payments are to be made by employers and workmen and for the indigent by the Government. But nothing in the book seems to me to justify the belief that this method is likely to solve the national problem. And Dr. Bauer never faces the situation which would arise in a time of prolonged unemployment, or what is to be done with improvident people who refuse to join the schemes. Far from being unsympathetic to the author's desire to avoid Government control, I believe most doctors in Britain would rejoice if our brethren in the U.S.A. could evolve a solution of the problem on voluntary lines. But this book gives little encouragement to this hope.

ALFRED COV.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Man, the Unknown. By A. Carrel. (Pp. 312. 1s. 6d.) W. Drayton, Middlesex: Penguin Books. 1948.

The author comments on man's place in the world and suggests remedies for our excessive industrialization.

Neuroanatomy. By F. A. Mettler, A.M., M.D., Ph.D. 2nd ed. (Pp. 536. 50s.) London: Kimpton. 1948.

A textbook for medical students.

Theory and Problems of Social Psychology. By D. Krech and R. S. Crutchfield. (Pp. 639. 27s.) London: McGraw-Hill. 1948.

A textbook for teachers and students of social psychology.

Síndrome Anémico do Kala-Azar. By C. Trincão. (Pp. 68. No price.) Lisbon: Sociedade Industrial de Tipografia. 1948.

A research monograph with extensive bibliographies.

Sex Variants. By G. W. Henry, M.D., and others. (Pp. 1,128. 40s.) London: Hamish Hamilton. 1948.

The personal histories of homosexual men and women, with notes on them.

Physiology. By A. D. Le Vay, M.S., F.R.C.S. (Pp. 209. 4s. 6d.) London: English Universities Press. 1948.

A short account for the layman.

Ulcer. By D. Cook, B.A., M.D. (Pp. 187. 5s.) Chicago: Medical Center Foundation and Fund. 1946.

The author elaborates his thesis that gastric ulcer is due to ischaemia of the mucosa caused by pressure from structures adjacent to the stomach.

Transplantation von Mensch auf Mensch aus dem Lebenden und aus der Leiche. By E. Kubányi. (Pp. 120. 12.80 Swiss francs.) Berne: Hans Huber. 1948.

A monograph on the transplantation of endocrine and other tissues from man to man or cadaver to man.

An Elementary Atlas of Cardiography. By H. Wallace-Jones, M.D., M.Sc., F.R.C.P., and others. (Pp. 108. 12s. 6d.) Bristol: John Wright. 1948.

Illustrations of electrocardiograms and skiagraphs, with annotations.

Die Indikationen zur Röntgen- und Radium-Bestrahlung. By H. R. Glauner. (Pp. 124. M. 7.20.) Stuttgart: Georg Thieme. 1948.

A short review of the conditions for which x-ray or radium therapy is indicated.

L'Indirizzo Psicologico nello Studio della Personalità del Reo. By P. Manunza. (Pp. 138. No price.) Cagliari: Società Editoriale Italiana. 1948.

An account of researches into the psychology of delinquents.

Cardiology. By W. Evans, M.D., D.Sc., F.R.C.P. (Pp. 310. 35s.) London: Butterworth. 1948.

A textbook for medical students.

Médecine Pratique. Edited by C. Lian. (Pp. 191. 700 francs.) Paris: L'Expansion Scientifique. 1948.

Lectures on a variety of medical topics delivered to students.

World of All of Us. Issued by the Church Missionary Society. (Pp. 58. 2s. 6d.) London: Church Missionary Society. 1948.

News from the letters of medical missionaries abroad.

A Surgeon's Guide to Local Anaesthesia. By C. E. Corlette, M.D., Ch.M., F.R.A.C.S. (Pp. 355. 35s.) Bristol: John Wright. 1948.

A practical guide intended for surgeons, not for physician-anaesthetists.

Atemregelung als Heilmittel. By L. Hofbauer. (Pp. 99. Sch. 25.) Vienna: Wilhelm Maudrich. 1948.

A short account of the treatment of chest disorders.

BRITISH MEDICAL JOURNAL

CONCERNING HOLES AND PEGS

That man is well who derives from what he does, and particularly from his energy expended for the common good, physical, intellectual, and emotional satisfaction. He tends to be ill if his needs in respect of such satisfaction remain unconsidered. Sickness, unhappiness, and inefficiency in the individual and in the group can be the dramatization of discontent cradled in disharmony between man and the conditions of his external social world. It is no new observation that for the maintenance of health and efficiency the tasks demanded of an individual should not in their demands exceed the limits of his total potential abilities and should not be too far below the upper limits of these. Yet in civil life it is not always easily possible to ensure that the immature shall enter that occupation which will offer him the opportunities that he must enjoy if he is to become a complete citizen and a hale individual. In the Army it is possible and greatly to be desired. In its fabric there is a multitude of holes of varying size and shape, definable and measurable. Among its recruits there is a multitude of pegs of infinite variety, differing in respect of physical, intellectual, and emotional qualities and of acquired and potential skills, some of which are amenable to accurate measurement. In this issue of the *Journal* Major R. T. Fletcher tells the story of the methods which in their sequence have been employed in the Army in attempts to pre-select the man for the job. The complementary story of the methods that have been devised to attune the man to his job belongs, unfortunately, not to the medical services but to the Directorate of Selection of Personnel. This dissociation of the purely medical assessment of the individual's physical attributes and the military assessment of his qualities in respect of employment was productive of much confusion and wasted effort.

To begin with, the civilian medical boards were responsible for the classification of a man into one of four grades of physical fitness for service. The Army medical and selection services then took up the task of specifying the form of employment that was suitable to his physical condition and of posting a particular recruit to a particular arm. The former attempted to devise a system of medical categories which would translate the civilian grades into terms of military employment. These grades differed in respect of visual acuity, ability to march long distances, general soundness of constitution, and of other manifestations of defect likely to affect the performance of military duties. As was to be expected, this system proved in experience to be exceedingly faulty. An Army unit is not composed of identical individuals performing uniform tasks. It is a diversified community in which there is a highly organized division of labour. Categorization by reference to physical attributes can be utterly misleading, since the

presence of physical defect does not necessarily imply functional imperfection.

No wonder then that during the war this system was so elaborated that at the end the series of categories demanded by its various permutations and combinations of physical characteristics, including subdivisions to include men over 41 and such as were fit for non-tropical and home service only, numbered no fewer than 72. That the system was itself inherently complicated, its administrative procedures cumbersome, and the underlying principles never completely grasped was clearly indicated by the stream of amendments and revisions which poured forth unceasingly. The system never fully succeeded in attaining complete correlation between physical condition and aptitude for employment, and continuous attempts were made to devise some alternative method likely to prove more flexible in application and more promising in results. It had become evident that any one of the many categories was related not to any one prescribed form of employment but to a multiplicity of occupations widely diverse in nature and requirements. In determining a man's category the medical officer or board had to decide not on the man's fitness to perform the job in which he was then engaged but rather on his capacity to perform all the numerous jobs that a man of his category might be called upon from time to time to undertake. Ability to carry out certain duties could not be regarded as evidence of fitness for any specified category. It became clear that the category of a recruit should be based upon a combination of medical classification and training recommendation. Schemes to this end were devised and tested. None was satisfactory.

Eventually it was decided to put to the test the system which had been invented and adopted by the Canadians—the Pulheems system. This was based upon the truth that modern warfare made ever-increasing demands, both qualitative and quantitative, upon the soldier in physical ability varying in nature and degree according to the exigencies of his particular employment, in the level of intelligence required to grasp the technicalities of military operations, and in temperamental stability as a primary factor in determining conduct in battle. The growing complexities of military service and the widely diverse occupations which it comprised called for the application of more precise methods in the selection of personnel, since success in any undertaking depended upon the capacity of each man adequately to fulfil the task assigned to him. Moreover, conservation of man-power implied the employment of every soldier in his proper capacity so that a maximum of working efficiency and a minimum of wastage might be ensured. The system correlated two essentials: a detailed qualitative assessment of the individual soldier and a qualitative analysis of occupational requirements. In it the emphasis was placed on performance and not on physical shortcomings.

Towards the end of the war this system was thoroughly tested by a series of trials, and its value was demonstrated especially in relation to the lower categories. It was found that before it could be universally applied much instruction would have to be given to medical officers in order to wean them from their saprophytic preferences. Now it is to be used by all three Services and is beyond the

experimental stage. As Major Fletcher points out, its usefulness is not restricted to the armed Forces: it can claim its place in industry. As yet it is by no means perfect; in it there is still much that is based on clinical judgment rather than on exact measurement. The Directorate of Hygiene seeks the help of the academic scientist and is willing to place at his disposal the unique research facilities that it can command. In the large-scale employment of this system there will be abundant opportunity, especially for the experimental psychologist, the physiologist, and the specialist in physical medicine, in collaboration with the Army Medical Services, to add to natural knowledge and at the same time to render service of great value.

It seems probable that this development will have its effect upon the medical curriculum. If the civilian practitioner is to be called upon to make use of this Pulheems system it follows that he will have to be given information concerning it and be taught the principles upon which it is based during the period of his professional education. It will be for the departments of social medicine to weave this into their courses.

SECOND THOUGHTS ON PROGUANIL

The combined ingenuity of chemists, pharmacologists, and experimental pathologists has in the past quarter of a century given to the world a great number of interesting and valuable pharmaceuticals. Yet the mortality among such compounds has been high, and many of them are to-day largely of historic interest. That it takes time to assess correctly the value of any new drug has been emphasized again and again by medical men; yet this still seems to be insufficiently appreciated, for too often in the past enthusiastic receptions have been given to new and relatively untried drugs about which over-optimistic hopes have been raised. Careful and prolonged trials are especially necessary with new chemotherapeutic compounds, and above all with new antimalarial drugs because of the diversity not only of the species of plasmodia but also of strains. In assessing new antimalarial drugs there are three important questions to be answered: Does the drug rapidly control clinical symptoms? Does it produce radical cures? Does it act as a true causal prophylactic or as a suppressive? Action on gametocytes is probably of less importance, more especially in hyper-endemic areas such as West Africa, where a few gametocytes more or less can hardly make any great difference to the public-health.

When "paludrine," now known as proguanil, first appeared in 1945 it was hoped, and at first perhaps with too much enthusiasm, that the solution to all the problems of the treatment of malaria had been found. It soon became apparent that, though acute attacks due to *Plasmodium vivax* are readily controlled by proguanil, the infection is not eradicated. Proguanil alone is thus inferior to a combination of pamaquin and quinine in the treatment of relapsing vivax infections. In addition it cannot be relied on to act as a true causal prophylactic. In the case of infections due to *P. falciparum* the evidence has been extremely confusing, but further light has been thrown on

the action of proguanil on this parasite by Sir Gordon Covell and his collaborators, whose paper we publish elsewhere in this issue. There is now general agreement from various parts of Africa and Asia that proguanil acts more slowly than mepacrine, quinine, or chloroquine in controlling acute attacks of malaria due to *P. falciparum*. Walls¹ found that quinine and proguanil were more satisfactory than proguanil alone, and Covell and his colleagues show that the fall of temperature is hastened and the duration of parasitaemia shortened by combining proguanil with quinine or mepacrine. This is of considerable importance, for the persistence of serious symptoms in infections due to *P. falciparum* may mean cerebral involvement or even the development of blackwater fever.

The second question is whether proguanil acts by eradicating the parasites, thereby producing a radical cure. Chaudhuri² drew attention to the existence in India of strains of *P. falciparum* which give rise to infections not radically cured by proguanil in doses of 300 mg. for 10 days. One patient in fact had a second attack nine days after treatment and a third attack 11 days later, a radical cure being finally produced by chloroquine. Fairley and his colleagues,³ working with New Guinea strains of *P. falciparum*, claimed to have produced a radical cure of 41 out of 41 naturally acquired infections and of 46 out of 47 experimentally induced sporozoite infections as a result of a 10 days' course of 100 mg. of the drug thrice daily. On the other hand Covell and his colleagues have now brought forward convincing evidence that proguanil alone does not produce a radical cure of a West African strain. In this respect it is inferior to mepacrine.

Uncertainty still existed whether proguanil was really a true causal prophylactic against *P. falciparum*. Fairley's experiments appeared to demonstrate conclusively that proguanil could act as a true causal prophylactic against a New Guinea strain of *P. falciparum*. Ciuca and his colleagues,⁴ working in Rumania with a long-established laboratory strain of *P. falciparum*, also found that of five subjects inoculated twice weekly with *P. falciparum* sporozoites over a period of four weeks none showed fever or parasites when 300 mg. of proguanil was given every week during the period of inoculation and for two weeks after the final inoculation. Observations were made over periods of at least 23 days after the final inoculation, but no sub-inoculations were attempted, nor was it proved that the subjects were susceptible to the strain of *P. falciparum* employed. In the Belgian Congo van Riel⁵ found that 300 mg. every week did not act as a true causal prophylactic; but, as Covell and his colleagues point out, the administration of the drug was continued only for 40 hours after the last possible exposure to infection, a period far too short to give any margin of safety. The experiments recorded by Covell and his colleagues show that proguanil can undoubtedly act as a true causal prophylactic against an African strain of *P. falciparum*. To be on the safe side, however, they recommend that for non-immunes a dose of 100 mg. should be taken daily.

While these investigations undoubtedly clarify the position with regard to certain African strains of *P. falciparum*, they urgently require further extension. Evidence accumulated during the war suggests that not all strains of

P. falciparum from Africa south of the Sahara are identical. African troops from the Belgian Congo stationed in Nigeria had a malarial incidence three to four times that of Nigerians serving in the same area. Gold Coast troops stationed on the north bank of the Gambia were more frequently and more severely attacked by malaria than Gambian troops alongside them. Studies on the effects of proguanil on other African strains of *P. falciparum* would therefore be of great interest.

There are other points on which further information is required if proguanil is to be extensively used. When, during the war years, large bodies of European troops were serving in West Africa, blackwater fever was abolished only when mepacrine was substituted for quinine, both in the suppression and treatment of malaria. If proguanil by itself cannot be relied upon to eradicate falciparum malaria in West Africa it is doubtful if it will have the power to abolish blackwater fever as does mepacrine. Secondly, there is growing evidence that proguanil produces resistant strains of plasmodia with comparative ease. It has already been shown that *P. gallinaceum* in fowls and *P. cynomolgi* in the monkey can be rendered resistant to proguanil⁶⁻¹¹: evidence is shortly to be published that the same is true of *P. vivax* and *P. falciparum*. Resistance against quinine and mepacrine is extremely difficult to produce.

One of the facts in favour of proguanil appears to be its low toxicity. However, there have been complaints of loss of appetite, reduction of weight, and lack of energy from some of those who have taken proguanil for considerable periods. Hughes and his colleagues¹² have noticed similar signs in the rat. Recent studies by Burn and Vane¹³ and by other workers^{14, 15} have shown that there is almost certainly a pathological basis for these symptoms, for doses of 900 mg. of proguanil in man reduce the acidity and volume of the gastric juice. Loss of appetite is a matter of moment to those Europeans who are stationed in such tropical areas as West Africa, for towards the end of a long tour the appetite is in any case rather poor and capricious. For Africans, whose diet is only too often deficient both quantitatively and qualitatively, it is obviously undesirable that they should take for long periods a suppressive antimalarial which may reduce still further their already inadequate intake of food.

In comparing the effects of mepacrine and proguanil in the prevention and treatment of falciparum malaria in West Africa it may be said that for prophylaxis both drugs must be taken daily. In a dose of 100 mg. daily mepacrine has very few failures: records are readily available of patients who, in spite of taking 100 mg. of proguanil daily, have suffered from attacks. Mepacrine is not a true causal prophylactic, but if continued as a suppressive will bring

about a radical cure. Proguanil is a true causal prophylactic for at least one strain, but does not produce a radical cure. Mepacrine does not injure gametocytes; proguanil inhibits their development in the mosquito. Mepacrine does not induce drug fastness; proguanil probably does. Mepacrine stains the skin and may cause psychoses, though the incidence is low—1.71 per 1,000 among 90,320 persons given mepacrine therapeutically or prophylactically.¹⁶ Proguanil may cause loss of appetite associated with decreased acidity of the gastric juice. The relationship, if any, of proguanil to the onset of blackwater fever is not yet known. It is claimed that chloroquine, 0.25 g. of the base, effectively suppresses malaria if given once weekly, but it has not yet been tested against West African strains of *P. falciparum*. It is thus doubtful whether the ideal drug either for the prophylaxis or radical cure of malignant tertian malaria has yet been discovered.

The necessity for the intravenous administration of anti-malarials is fortunately rare and occurs for the most part only in cerebral emergencies and where the patient is unable to swallow. The effects of proguanil acetate, soluble proguanil, when given intravenously are recorded by Chaudhuri and Chakravarti on page 91. The acetate, however, has now been replaced by the more soluble lactate for intravenous use. Further investigations on the comparative effects of proguanil lactate and quinine when given intravenously will be of considerable interest, more especially if carried out on patients with no immunity or tolerance to malaria.

THE DANGERS OF HEROIN

Most doctors will agree with Sydenham that they would not wish to practise medicine if denied the use of opium, but they seldom pause when they prescribe this drug or its derivatives to consider the social implications of the narcotics. It is to this aspect that the Permanent Central Opium Board has drawn attention in a report which was recently summarized in *The Times*.¹ The Board is particularly concerned with the increase in the medical use of heroin. It has been found in the past that a rise in the legitimate use of drugs of this order precedes an increase in addiction and in illicit supply. In 1931 an international conference noted the wide variations in the demands of various countries for heroin for medical use and commented on the disparity in professional practice. Acting on the recommendations of this conference, many countries, of which the United States was one, prohibited the importation and manufacture of this drug. In 1946, 71 countries required less than 1 kg. per million inhabitants, while one, Finland, required more than 25 kg. The Finnish Government estimates its country's requirements for 1949 as 51 kg. per million inhabitants, representing a more than sevenfold increase in consumption since 1936. The needs of Italy and Sweden have also risen.

The dangers of heroin are well known. Addiction is acquired more rapidly than with any other drug; once acquired, the disorder progresses with greater speed and is marked by a more profound and disastrous moral degeneration than in any other addiction. Cure is more difficult, and sudden withdrawal may prove fatal. In the light of these facts it is clearly the duty of the medical profession to examine again the therapeutic value of this substance

and to weigh it against its social danger. When first introduced in 1898 it was claimed that, although heroin lessened the cough reflex and slowed respiration, inspiration was deepened and increased in force. This alleged advantage over morphine has not been confirmed. Its effects on the alimentary tract are certainly less prominent than those of morphine, but where pain needs relief and these other actions are undesirable dihydromorphinone can be employed. The choice of effective analgesics has been widened by the introduction of pethidine and similar compounds. For the control of cough codeine or one of its derivatives, dihydrocodeinone or dihydrohydroxy-codeinone, will suffice in most cases. In short, morphine or some related drug can always be used as effectively as heroin. Since 1931 the profession has been deprived of heroin in some 26 countries without evident disadvantage. Pharmacological opinion has long held that its social dangers overshadow its therapeutic importance. It must be granted that there is justice in the Permanent Central Opium Board's claim of "an *a priori* case for its total abolition."

DISEASE OF THE BREAST

It remains a sad fact that even with all modern methods of investigation and with the results of various therapeutic methods recorded in thousands of cases it has not yet been possible to define clearly, either histologically or clinically, the more frequently encountered pathological conditions in the breast. To remove a breast unnecessarily is a surgical crime; to leave a breast *in situ* when it contains an undiagnosed or misdiagnosed malignant tumour is almost worse. Are there any beacons to help the practising surgeon to steer between the Scylla of commission and the Charybdis of omission?

On the one side is the obviously innocent tumour, such as the fibro-adenoma, easy to diagnose and amenable to simple treatment without producing deformity or loss of function. On the other is the clinically obvious carcinoma, which by the time it has reached this stage is probably a growth of some years' standing and may even have spread either obviously or microscopically to far distant parts. In this class the signposts to treatment are also clear—pointing to a judicious mixture, varying with each growth and each individual, of surgery and radiotherapy. Two papers recently published in the *Journal* were concerned with this aspect of the problem, the first by Sir Cecil Wakeley¹ and the second by Mr. Victor Riddell.² Unfortunately the results of treatment, especially when the relative accessibility of the breast as an organ is taken into consideration, are woefully depressing to the clinician who follows up his cases sufficiently long. He is a fortunate man who can say that one-third of his patients are alive and well five years after treatment, and even in this group lie traps for the unwary. Fat necrosis³ is an example, for an adequate history is frequently lacking; another is the condition of plasma-cell mastitis, described by Dr. Max Cutler elsewhere in this issue.

Between the two extremes and far outnumbering them come that mass of cases and conditions labelled by one of a dozen or more names—the generic but now rightly repudiated term for which has previously been "chronic interstitial (cystic) mastitis." Also published in this issue is a paper by Mr. D. H. Patey, who describes two common non-malignant conditions of the breast—the "pain" syndrome and "cystic disease." The separation of the former condition into a class of its own—a subjective disorder without obvious clinical signs and due either to cancerophobia or to a psychosexual disturbance—is timely if its

recognition serves only to distinguish one among the many manifestations of disorder in this vague intermediate class. Cystic disease, on the other hand, would appear to present innumerable problems. Undoubtedly there are many perfectly innocent cysts, but Patey himself speaks of a possible hormonal cause, with all the conflicting and possibly sinister implications that this suggests. Again, he describes a diffuse cystic disease in which accurate diagnosis is only "possible after exploration and naked-eye and microscopical examination." For the solitary cyst he advocates diagnosis by aspiration, a method also approved by Pybus,⁴ who goes further and treats the condition by injection of quinine and urethane. But cysts, apart from the retention cyst of the lactating breast, are essentially degenerative in character, though they may vary widely in type, in contents, and in pathological significance. Dawson⁵ divides all proliferative conditions of the breast into adenosis and epitheliosis. The former term (also approved clinically by Atkins⁶) comprises glandular growth which produces more and larger lobules and is essentially a response to physiological stimuli. Epitheliosis, on the other hand, implies proliferation inside existing ducts, and degeneration of these cells leads to cyst formation, with perhaps secondary papilliferous outgrowths or uncontrolled extension into surrounding stroma. Such cells (and cysts) are according to Dawson a very probable "*Anlage*" of carcinoma. A good, if rare, example of this condition is "comedomastitis" where proliferation within the dilated ducts is still non-invasive. Comedomastitis was described recently by Tice, Dockerty, and Harrington⁷ and was mentioned by Mr. J. M. Jackson in a letter appearing in last week's *Journal* (p. 71).

Such considerations as these would seem to place cystic disease in a far from well defined category and to throw considerable doubt on its universally non-malignant character. The other large group of non-malignant breast tumours—the fibro-adenoses (nodular non-cystic breasts)—have a greater claim to innocence, though it is perhaps worthy of record that they too in the process of reaching natural quiescence by fibrosis may also develop microscopic cysts. There are still many obscurities in this field of pathology, and since it is patients as well as tumours that are concerned the perhaps hackneyed aphorisms of the clinicians still merit attention: "No fibro-adenoma occurs after the age of 35"; "A lump in the breast is carcinoma until proved otherwise"; "It is better to look and see than wait and see."

PRESENT-DAY PNEUMONIA

A valuable analysis of the characters of pneumonia and its response to the different treatments used in three recent periods has been made by Israel and his colleagues.¹ Their material consisted of patients admitted to the Philadelphia General Hospital during the twelve-month periods (including the winters) of 1936-7, 1940-1, and 1945-6. After first eliminating all patients over 60, tuberculous, post-operative, and terminal cases, the numbers available in these periods were respectively 368, 540, and 420. Of these 261, 429, and 312 were diagnosed as having lobar pneumonia, and consideration was restricted to these groups. In the first period there was no chemotherapy, and the only specific treatment used was serum in five cases: the mortality was 23.3%. In the second period all but 20 patients (wrongly diagnosed) were given sulphonamides, and the mortality was only 5.4%. In 1945-6 penicillin was also available: it was used alone in 36 cases and together with sulphonamides in 113; sulphadiazine or sulphadiazine with sulphamerazine was given to another 153; and 10 patients for some reason received no specific treatment. It might have

¹ *N. Engl. J. Med.*, 1948, 238, 205.

been expected that the additional therapeutic resources available in the most recent period would reduce mortality still further, but it did not; there was on the contrary a slight rise, to 6.5%, and a distinct increase in the mean duration of fever and the length of stay in hospital.

The apparent reason for these differences is to be found in a change in the characters of the disease, notably in its age incidence. In 1940-1 the fourth decade had the largest number of cases; in 1945-6 the fifth and sixth each contained more than any lower age group. At the same time there was a marked increase in the proportion of patients without leucocytosis. This appears at first sight to suggest that this group included a number of cases of virus pneumonia, the course of which would be relatively unaffected by chemotherapy. That this is not the explanation is evident from the careful analysis made. It would be expected that most of these supposed virus pneumonias would occur in the patients with leucocyte counts between 5,000 and 10,000, but in fact their mortality did not differ, and their decline of fever was more rapid than those with a leucocytosis. Low leucocyte counts and a retarded response to treatment were also seen in patients whose pneumonia was proved to be of bacterial aetiology by cultivating pneumococci from the blood.

Nevertheless, the authors are inclined to the view that virus infection is responsible for the change in the character of the disease in quite a different way. Their hypothesis, originally put forward by Francis, is nothing less than that a virus is concerned in producing lobar pneumonia generally, with varying degrees of superimposed bacterial infection. The facts which they have to explain can all be accounted for by a hypothetical recent change in the relative importance of the virus and bacterial factors. This is indeed a revolutionary concept and not one which will be readily accepted, especially in view of the ease and regularity with which typical lobar pneumonia can now be produced experimentally with pneumococcus culture. It is, nevertheless, an interesting possibility to bear in mind. Comparable studies of present-day pneumonia should certainly be made elsewhere in order to see whether the tendency observed by Israel and his colleagues is general.

SICKNESS TREATED IN HOSPITALS

In a leading article¹ on the subject of morbidity surveys we have already referred to the investigation carried out by the Glasgow Health and Sickness Bureau of hospital-treated sickness among the population of Stirlingshire. This well-produced report,² published by the Nuffield Provincial Hospitals Trust, covers the period of twelve months beginning on Oct. 1, 1946, and records the hospital attendances of all the residents in the county irrespective of whether they received treatment at hospitals inside or outside Stirlingshire. No record, however, was made of patients who were treated in nursing-homes. In-patients during the year numbered 10,560 and out-patients 18,009, out of a total population of 183,200—i.e., one person in every seven of the population had hospital care during the year. This rather startling finding must be qualified. An examination of the tables shows that over one-third of the in-patients were women who entered hospital for their confinements or babies born in hospital, and over one-third of the out-patients attended for injuries. With the omission of these groups the proportion of the population receiving treatment at hospitals was one in thirteen. The authors stress the difficulties of interpreting hospital data in relation to the general sickness in a com-

munity, since many other factors (geographical, social, environmental, custom, etc.) besides the disease determine whether or not a patient enters hospital. Apart from mothers and babies the three largest groups of in-patients were admitted for the treatment of diseases of the digestive system (1,217 patients), infectious and parasitic diseases (760 patients), and injuries (719 patients).

The data have been extensively analysed, the patients having been grouped according to disease, age, occupation, area of residence, duration of stay in hospital, condition on discharge, etc. It is always difficult to present a mass of detail in a manner that gives the maximum information without ambiguity and at the same time in a form that is generally understood. Percentage distributions are generally not informative—the fact that a specific disease forms a larger proportion of the total admission in one social class than in another does not convey any useful information unless the numbers exposed to risk by age and sex are known. There is also a risk of gaining false impressions from percentage distributions. Taking figures from a table showing the percentage in age groups of the total number of patients admitted for certain diseases, the authors discuss the "peak" incidence—for example, they find that the peak incidence for circulatory diseases in females is at ages 35-54. Actually, when allowance is made for the varying numbers exposed to risk in each age group, it is clear that the peak vanishes and the incidence increases throughout life—a finding to be expected from the known trend of mortality. The presentation of some of the tables could be improved, and some omitted since they give no useful information. The division of the percentage of hospital admissions in each age group by the percentage of population in each age group seems clumsy and is no improvement on the usual method—i.e., admissions expressed as a percentage of the population exposed to risk. There is little to be learnt from a comparison of the duration of stay in hospital for all causes combined with figures obtained from old records, since methods of treatment and hospital policy have changed considerably, and, moreover, with the discovery of many auxiliary aids to diagnosis a larger number of patients are admitted for investigation (generally only for a few days) than formerly. This investigation, by breaking new ground, provides useful guidance for future inquiries.

INCREASE OF MILEAGE FUND

The General Medical Services Committee sent a deputation to the Ministry of Health on Dec. 22 to put before it the problems at present facing rural practitioners and to urge the need for the relief of financial hardship suffered by so many of those practising in rural areas. As is announced in this week's *Supplement*, the Ministry of Health has proceeded to lighten the load by increasing the Mileage Fund by rather more than 50%. This Fund has been increased by £700,000—from £1,300,000 a year to £2,000,000. The increase is made up by a new provision of £500,000, and by £200,000 from the Special Inducement Fund. The new Fund of £2,000,000 will be retrospective to July 5, 1948, and in the case of some practices this will increase the annual income by several hundred pounds. This substantial increase in the Fund is a tribute to the pertinacity of those who are negotiating on behalf of the medical profession, and a welcome sign that the Ministry of Health will respond to a strong case cogently put. It is, of course, yet to be seen to what extent this will relieve the financial anxiety of rural practitioners, and whether it will provide a sufficient reward for those general practitioners who care for the health of the people who live in the four-fifths of Britain that still remain the countryside.

HAEMATEMESIS AND MELAENA*

BY

NORMAN C. TANNER, F.R.C.S.

Senior Surgeon, St. James Hospital, London

Cases of massive gastro-duodenal bleeding treated at St. James Hospital, London, in the period of 1941-8 numbered 650. Peptic ulcer and gastritis accounted for 85% of these cases, as is shown in Table I.

TABLE I.—Final Diagnosis

Gastric ulcer	290
Duodenal ulcer	195
Anastomotic ulcer	29
Oesophageal ulcer	2
Gastritis	40
Carcinoma of the stomach	24
Portal hypertension	22
Hiatal hernia	3
Simple tumour of the stomach	4
Gastric diverticulum	1
Aneurysm of the aorta	1
Pancreatitis	1
Uncertain, duodenal diverticulum, etc.	38
Total	650

Although oesophageal varicosities are a typical feature of portal hypertension, it is not so well known that varicosities may occur in the body of the stomach, and they were observed gastroscopically in one of these 22 cases. There is great difficulty in arresting the haemorrhage in this disease, and I recommend the use of an inflatable bag in the lower oesophagus which can, on distension, obstruct the collateral blood flow from the coronary veins and so reduce the pressure in the oesophageal veins to normal or less. (See Fig. 1.) A modified Miller Abbott tube is useful for this purpose and need not press on the bleeding area.

Severe bleeding from carcinoma of the stomach is not necessarily a sign of inoperability, for of 24 such cases with severe bleeding 13 were eventually treated by gastric resection and left the hospital well, though 4 required a total gastrectomy.

Gastroscopy is of value in the diagnosis of some cases of hiatus hernia; the gastroscope may first enter the supra-diaphragmatic part of the stomach and then the sub-diaphragmatic compartment. Above the diaphragm a violent heaving pulsation is seen, due to the immediate proximity of the heart, with an opening below, which varies in size with respiration, through the oesophageal hiatus in the diaphragm. If the gastroscope is passed through this opening the normal quiet appearance of the body of the stomach is seen.

FIG. 1.—The bag inflated in the lower oesophagus, obstructing hyper-tensive portal flow, with aspiration or feeding tube in the stomach.

Gastritis, particularly an atrophic gastritis associated with achlorhydria, may be the only positive finding in many cases of gastro-duodenal bleeding, as in 40 cases in this series. Why is the atrophic stomach prone to bleed? Occasionally a small subacute gastric ulcer is found, but in the majority of cases there is no visible ulcer by the time the patient is examined gastroscopically. In two cases minute erosions were seen directly overlying the submucosal vessels which appear so prominent in atrophic cases. I believe that in these cases minor erosions which might heal without incident in normal mucosa penetrate one or more of the submucosal vessels and cause a haemorrhage. The value of gastroscopy in this series was amply demonstrated.

*Abridged version of the first Simpson-Smith Memorial Lecture, delivered at the West London Hospital Medical School on June 10, 1948.

Peptic Ulcer and Gastritis

In England a policy of selective surgical intervention has been followed in this group, cases thought likely to fare badly under medical management being treated surgically. This policy has certain difficulties. If one waits for repeated bleeding, or waits to be certain that the bleeding is of a lethal type, then several days may have passed and the patient may be in poor condition for surgery. An alternative method is to operate on all cases of bleeding in patients who are known to have peptic ulceration and to operate at once, as recommended by Finsterer, on a patients who have a second haemorrhage even if they have no history of peptic ulceration.

How can we discover the advantages or otherwise of surgery? Comparison of the results of different workers is practically valueless. The ages of different groups of cases recorded vary widely; in this series 38% of the patients were aged over 60 compared with the more usual proportion of 2 to 20%, and two thirds of the deaths occurred in this group. Long lists of cases of gastro-duodenal bleeding treated surgically with few or no deaths are of little value; such figures may be readily obtained if only good risk cases are accepted. I therefore adopted a different approach. With the co-operation of the medical staff at St. James Hospital all the cases of haematemesis and melaena were admitted to my wards. A routine method of treatment was decided upon and printed on charts displayed in the wards. The intention was to remove as many variables as possible and then vary one factor only, the factor of surgical intervention, to discover its effect on mortality. It was of course impossible to exclude some variables. The introduction of the sulphonamides and penicillin had some effect, and the depletion of staff during the war also affected the results. Bombing has a bad effect on surgical mortality, and the incidence of bleeding rose during the "fly bomb" period. The total mortality figures were as follows:

Whole Series.—650 cases; 85 deaths; mortality 13.0% (number over age 60 is 249=38%).

Peptic Ulcer and Gastritis Group.—586 cases; 62 deaths; mortality 10.5% (number over age 60 is 224=38%).

During the first phase of this period, 1941-3, operation was avoided so far as possible, and the cases operated on were the persistently bleeding survivors. In the next period, for six months of 1944, early or more frequent operations were undertaken and gastrectomy was almost invariably performed. The period was terminated by the advent of the flying bombs, which made surgery inadvisable and difficult. The mortality rose during this period. Following this, operation was a little less readily undertaken, and, instead of making it a rule to perform gastrectomy, the simplest and safest method of controlling the bleeding was used. This brought down the mortality to a low level.

In 1948 things were sufficiently stable to try the effect of early surgery in a much higher proportion of cases, and so from Jan. 1, 1948, the dictates of Finsterer were followed. This increased the operation rate in the first four months of the year to 41%, and during that time there was no death, despite the advanced age of many of the patients. Table II clarifies these points.

TABLE II.—Peptic Ulcer and Gastritis

	No. of Cases	Over 60 Years	Operated on	Mortality	Average Age of Patient who Die
Period 1, 1941-3. Operation avoided if possible	193	33%	5%	10%	62
Period 2, Dec., 1943-June, 1944. Operation earlier, always gastrectomy	60	33%	15%	20%	62
Period 3, June, 1944-Dec., 1945. Simplest operation to stop bleeding, early	175	39%	11%	7%	66
1946	66	36%	8%	11%	61
1947	71	32%	15%	15%	67
Period 4, 1948. "Finsterer" ..	22	45%	41%	0%	—

This fourth group is too small to be significant, but will be extended. Up to Oct. 14, 1948, 60 cases had been admitted, 35 (58%) being treated by emergency operation. Of the 60 patients, two (3.3%) have died, but one of these was bled too severely to move to the operating theatre and the second was a bed-ridden man aged 67 who had been bleeding on and off for three months. It must be acknowledged that the series is a fortunate one.

All the operations were performed under local analgesia, most of them by myself, but several by two assistants after they had spent two years in assisting at operations on considerable numbers of gastro-duodenal cases. So far as the precise surgical procedure is concerned, I considered it unwise to start the operation with a fixed determination to perform a gastrectomy; although that is undoubtedly the most certain way of stopping bleeding. In most bleeding gastric ulcers a gastrectomy is the easiest treatment. In extensive deeply penetrating ulcers in feeble persons I was often content to separate the ulcer edge from liver and pancreas and then firmly suture up the resulting opening in the stomach, taking care to include the whole crater edge in the sutures. A secondary gastrectomy has occasionally been necessary later. This procedure has undoubtedly saved some very fragile patients from death. In cases of duodenal ulcer the anterior wall of the duodenum is opened, the ulcer edges firmly approximated with deep silk sutures, and the duodenum repaired; this obstructs it, and so a gastro-jejunostomy is necessary. Although one patient bled again some days after this operation, it has given good results on the whole and has saved lives.

Finally, I believe that where there are good facilities and surgeons interested in this subject the freer use of surgery in the arrest of gastro-duodenal bleeding may give better results than those hitherto obtained. The method of deciding on a definite policy and observing the effects on the mortality of varying this policy may lead to further enlightenment.

Correspondence

Infective Ear Disease

SIR.—Your leading article on infective ear disease (Dec. 18, 1948, p. 1068) reviews the problem and discusses Mr. Colin M. Johnston's paper (p. 1049) on the same subject. It states that "it seems certain that regular daily treatment is the best method of clearing up infected ears." Is this true of suppurative otitis media? Before factory managements are persuaded to set aside facilities, including valuable nursing personnel, and workers are persuaded to spend their working time in making daily visits to factory clinics, the evidence must be considered. Daily treatment must inevitably consist, as Mr. Johnston points out, in a nurse or orderly syringing the ear or cleansing the ear by dry mopping and instilling drops. I know of no method more calculated to perpetuate infection: the easiest way to set up middle-ear discharge in a case with dry perforation is to syringe the ear; does not a suppurating ear so treated become dry despite rather than because of such treatment?

Mr. Johnston's paper is an abridged version of his full report to the M.R.C., and comments are to be related to the abridged rather than the full report. Are his criteria of cure adequate, bearing in mind the fact that of 37 cases of "immediate cure" examined by him 6-18 months after cessation of treatment 46% were found to have relapsed—a result not surprising in the condition, itself liable to intermittent activity? Moreover, the average duration of treatment was 5.2 weeks, and it seems likely that the average number of treatment attendances was 25-30. Of 274 cases some two-thirds would be the simple type of otitis, tubal infection, or tympanic sepsis, for only 90 showed granulations or polypi and six cholesteatoma. Moreover, of the polyp cases a number would arise from the tympanic annulus, with excellent prognosis. That "immediate cure" resulted in 80% of cases treated to conclusion is therefore not surprising, but I submit that a result as good could have been obtained with far less treatment.

In such cases treatment by an otologist perhaps once, perhaps repeated at weekly intervals three or four times, will yield equal results. The essentials are very careful toilet of the meatus and application of 20% silver nitrate, which is far preferable to chromic acid or trichloroacetic acid; it is an effective caustic and need not be confined to the precise area of the middle ear, being harmless in the external ear and indeed helpful if, as frequently occurs, otitis externa accompanies the otitis media. The application of silver is immediately followed by free insufflation, not light dusting but largely filling the meatus with pulv. P.S.U. (sulphathiazole 10 parts, urea 1 part, penicillin 2,000 units per gramme). Such treatment is only with extreme rarity followed by skin reactions.

In cases of tubal infection (antero-inferior perforation, discharge of mucous type, notably influenced by occurrence of coryza) infection in the nose, sinuses, or nasopharynx requires treatment, but deviation of the nasal septum and tonsillar or dental infection are rarely significant in the otitis.

More important, though less numerically, than these "nuisance cases" of otitis media are those with cholesteatoma or osteitis extending beyond the tympanic annulus, and I hope that Mr. Johnston will be able to amplify the information he has given, to record the number of cases showing attic perforations and granulations persisting despite treatment and correlate the results of treatment with these findings. It would seem that he takes too tolerant a view: to regard cases showing persistent pus in the middle ear not extruding through the perforation as "quiescent" is to misunderstand the whole pathology of the middle ear cleft. In days past radical operations were done in cases of persistent middle-ear suppuration of the tympanic sepsis and tubal type: that is history, and best forgotten. But the otologist who takes too lightly his cases of cholesteatoma, or deep osteitis, or granulations of antral origin incurs much responsibility: indefinite supervision will be required, and sooner or later operation will be advised—or the patient will fail to continue attendance, for which the otologist must blame not the patient but his own dilatory decision. In these cases, correctly diagnosed as such (a small proportion only of the total), there is expectation only of continued discharge, progressive increase of deafness, and possible sudden complication of the most serious nature.

Preparations and Appliances

ANAESTHETIC APPARATUS FOR INFANTS

Dr. D. F. REES, of Twickenham, writes: Below is described a simple method of anaesthetic administration evolved for that very awkward patient the tiny baby—i.e., from birth to the early months of life. It is based on Ayre's open T-piece method without the need for intubation. The apparatus consists of the inlet junction and mask mounting of a Waters assembly with a length of elephant tubing (6 in.—15 cm.—has proved satisfactory) fitted on to the absorber mounting. The valve is screwed shut and the feed-tube is connected to a normal Boyle machine.

In major abdominal operations—e.g., for pyloric stenosis, exomphalos, torsion of gut, and intussusception—it provides ideal conditions, with quiet respiration and adequate relaxation and oxygenation. It has the advantage over cyclopropane that an air-tight fit of the mask is unnecessary and that the administration can be performed by the relatively unskilled. Finally, the lightness of the apparatus renders the fatigue of administration minimal. In minor surgery, such as circumcisions and talipes manipulations, it is equally effective, and dispenses with the cumbersome "rag-and-bottle" method and the nuisance of preparing several Schimmelbusch masks in the event of a long list. To obviate risk of explosion when cauterizing naevi and warts a non-inflammable mixture can be administered at will.

As a guide, 2 litres of oxygen and 4 litres of nitrous oxide, with the ether tap of the standard Boyle fully open, slide up, and ether to the 6-oz. (170-ml.) mark, quickly provide adequate anaesthesia for abdominal work. The large volume of gas-flow plus the non-gastight fit of the mask ensures against CO₂ build-up under the latter. A diagram is included more to emphasize the simplicity of the apparatus than to clarify the above description.

Operation should be advised after trial of conservative treatment, for it is only after such treatment in many cases that the precise pathology can be determined. Otoscopy and trial treatment of short duration are all important—neglect x rays, so often unhelpful and not infrequently misleading in otology. Operation must be performed according to the operative findings and be as limited as the disease permits. In these cases the disease is in the antrum and/or attic, and the lower tympanic and tubal region are best left undisturbed in almost all cases. The transmeatal route gives direct access to the site of disease and greatly speeds up convalescence and healing. The operation involves only 3 to 4 days in bed, 8 days in hospital, and dressings once weekly for 5 to 6 weeks. The only justification for postponement of so simple a treatment is the desire to spin out as long as possible still good hearing in the diseased ear, the other ear being more deaf: the surgeon fears that in dealing with extensive disease he will encroach on still functioning hearing mechanism. Such cases do occur and they must be watched carefully; sooner or later spread of disease, increasing the indication for operation or increasing the damage to the hearing, will bring the patient to operation.

Mr. Johnston's findings throw light on the importance of the problem of chronic otitis: we must be sure we tackle in the right way the disease in all its forms.—I am, etc.,

Canterbury.

T. A. CLARKE.

SIR,—As a school medical officer, I read Mr. Colin M. Johnston's paper (Dec. 18, 1948, p. 1049) with great interest, as infective ear disease presents an important problem among the school population. In fact, in a sample of 1,241 "defects discovered at routine examinations" which I analysed recently I found that 12.0% were assigned to diseases of the ear, nose, and throat—a figure almost identical with the 12.7% quoted by Mr. Johnston as occurring in a sample of 11,956 military out-patients.

I believe that this problem should be tackled from the epidemiological standpoint, in particular by the study of the infecting organisms, and I was disappointed to find no reference to bacteriology save a passing remark as to the possible growth of penicillin-resistant organisms in otitis externa. The following examples of bacteriological studies on pus from cases of otorrhoea will illustrate this point: (1) Pure growth of *Str. haemolyticus*—slightly "sulpha"-resistant and sensitive to penicillin. (2) (a) *Staph. pyogenes*—"sulpha"-resistant, penicillin-sensitive; (b) *Bact. coli*—resistant to sulphonamides and penicillin. (3) *Staph. pyogenes*—"sulpha"-resistant, penicillin-sensitive. (4) *Staph. pyogenes*—"sulpha"-resistant, slightly resistant to penicillin.

In none of these cases could chemotherapy, local or general, have been used successfully without this bacteriological evidence. In addition, an inspection of the findings affords a clue to epidemiology. Case 1, which was of recent origin, was associated with an organism of epidemic strain which was responsible for an outbreak of tonsillitis in the area. The other three cases were of longer standing. The staphylococcus may either have been of nasal origin or have been introduced as a contaminant during amateur efforts at treatment by the mother. In Case 2 the presence of *Bact. coli* supports the latter theory.

While studying a small outbreak of otitis media during the first quarter of 1948 I was impressed with the way in which parents consistently neglected to obtain advice in the early stages when severe earache was the predominant symptom—the stage in which systemic chemotherapy has the greatest chance of overcoming the infection. The onset of otorrhoea was regarded as desirable in that pain was relieved, and even then no advice was sought for periods which extended up to 14 days. The problem is therefore one of education and early ascertainment. As regards the latter, a policy which insists on exclusion from school of all cases of otorrhoea will result in treatment being obtained fairly early.

I am of the opinion that there is a good case for co-operation between otologist, bacteriologist, and epidemiologist in this field, and that by good team work, in which incidentally each must have respect for the others' outlook, a successful attack can be launched on this obviously serious cause of ill health in all sections of the population.—I am, etc.,

Bexley, Kent

A. J. DALZELL-WARD.

Treatment of Simple Ganglion

SIR,—I am delighted to read in the letter from my old friend Mr. Eric Coldrey (Jan. 1, p. 32) that he advocates rupturing simple ganglia rather than excising them. I entirely agree with him, both that this is sound practice and that it is not sufficiently frequently taught. It should be given a trial in almost every case. The ganglion in the commonest position, that on the dorsum of the wrist, is usually ruptured fairly easily, but that on the palmar aspect overlying the radial artery at the lower end of the radius is very resistant to rupture and often rather tender. I always use my two thumbs, one placed over the other, to apply the rupturing force. It is perhaps wise for textbooks to continue as they do to recall the well-aimed but surely traditional blow from the family Bible, as students are so ready to remember the bizarre and will know that rupture of a ganglion is a recognized practice.

But I most sharply disagree with Mr. Coldrey on two points in his letter. He says, "The results of treatment are very good indeed; most cases can be dispersed, and few recur." I used to believe the same, as few patients returned after rupturing the ganglion. But some years ago when I began following up my cases I realized that in about two-thirds of them the ganglion re-formed. However, although the betting is 2 to 1 against, the simplicity of the treatment is such as to prompt me to continue to give it a trial in all cases. I also entirely disagree with Mr. Coldrey when he says that simple ganglia arise from tendon sheaths. This is most dangerous teaching, for if a dissection for removal of a ganglion is carried out only as far as the tendon sheaths recurrence is very probable. If, in a bloodless field, the tendons and their sheaths are carefully retracted the ganglion will be seen to arise from the capsule of a joint, and this part of the capsule should be excised. Even then a few ganglia may recur. The only common ganglion that does not arise from a joint capsule that I know of is the interesting tiny tender one situated in the palm over a metacarpo-phalangeal joint.

A longitudinal incision on the back of the wrist is always more unsightly than a ganglion, but it is still being used—and much too frequently.—I am, etc.,

London, W.1.

JOHN HOSFORD.

SIR,—I have read Mr. Eric Coldrey's letter (Jan. 1, p. 32) with astonishment. I have re-read it to see whether my first impressions were incorrect. The more I peruse it the more I wonder whether he and I are living in the same world. Is it true that in "many cases a wrong diagnosis is made—e.g., fibroma, neuroma, osteoma, chondroma, bursa, and even sarcoma"?

Is it really true that some of the treatments ascribed to surgical textbooks such as "hitting the swelling with a hard object" are really described in recent editions? Is it really true that excision of a ganglion "is a major surgical procedure necessitating a general anaesthetic and subsequent rest, and leaving a permanent and often unsightly scar"? Is it really true that the "jelly can be seen to disperse in the tendon sheath"? Is it still believed that "a ganglion is a collection of jelly in a diverticulum of the sheath"?

For twenty years I have been fascinated by discussion about the simple ganglion, and, probably to the annoyance of my house-surgeons, who have felt that I was robbing them of their just dues, I have preferred to carry out the operation rather than entrust it to those who do not know on what they are operating. In twenty years I have found one ganglion arising from a tendon sheath. Two arose from the middle of the shaft of the first metatarsal. All the others arose from a joint. It is the failure to realize how deep is the origin of the ganglion, so that excision is incomplete, that results in recurrence. The complete excision of a ganglion leaves a small hole in the capsule of the joint from which it has arisen. To describe the operation as a major surgical procedure is to travesty the words. Most careful asepsis is required as in all operations. A local anaesthetic will suffice for all but the very nervous patients. Subsequent rest is required only for those cases where activity would delay the healing of the wound.

If Mr. Coldrey had examined textbooks he would have found an interesting swing over in the last fifty years. In the earlier textbooks a ganglion was described as arising from a tendon

sheath; later editions give approximately 50% in favour of the tendon sheath and 50% in favour of the joint. The more recent editions give a much higher percentage describing the true origin of a ganglion.

About diagnosis of ganglion I have nothing to say, except that I am surprised that any surgeon would admit mistaking a solid osteoma or chondroma for a cyst, however tense it was.—I am, etc.,

Manchester

W. SAYLE CREER.

SIR,—I agree with Mr. Eric Coldrey's view (Jan. 1, p. 32) that the present teaching on the subject of simple ganglion is inadequate, especially as to its treatment. My late chief and I had a ganglion each near the insertion of the right flexor carpi radialis. It is interesting that in both of us anxiety would cause temporary enlargement of the ganglion. For instance, in my own case this would begin with pain about three days before an examination and later subside. A sharp tap with a small mastoid hammer would hasten the gradual subsidence. In about two years the swelling disappeared for good. Many of these ganglia are said to be tuberculous.

The continuous-pressure method of reduction by one's thumb or knuckle is very efficacious, especially if the ganglion ruptures during the proceeding. The second method quoted—viz., hitting the swelling with a hard object such as a book—is clumsy, as Mr. Coldrey says, but carried out with a more accurate and decisive technique it rarely fails. A small mastoid hammer, being heavy for its size, properly used results in the instantaneous disappearance of the swelling, much to the patient's interest and amazement. One may quickly establish a local reputation as a champion ganglion-smasher. The only failures known to me have been when the sac has been thick-walled. I have never seen the method cause any spread of tuberculosis. Apparent incompleteness of cure may result from the presence of a second and much smaller ganglion hidden by the first, or by incomplete dispersal of the jelly and subsequent thickening of the sac. It is as well, therefore, not to fail at the first attempt. The method requires good positioning and the exercise of a certain amount of nerve to avoid damage to bone and yet ensure a correct knock. A small torch applied over the swelling often aids the diagnosis. Two or three days may be required for the pain to subside after such treatment.

I agree that the other methods mentioned by Mr. Coldrey are not always successful. They are seldom required if reduction or cracking has been employed. Excision may result in local disaster and often in keloid. It is also sometimes very troublesome to perform. It seems to me that the subject could be discussed with advantage both to the patient and the doctor. The natural history of an untreated ganglion has not been authoritatively given by anyone, as far as I know. A ganglion which quickly arises from hard manual work or from strain generally cures itself.—I am, etc.,

London, W.1.

G. H. COLT.

Mallet Finger and Simple Ganglion

SIR,—I was very interested to see Dr. W. J. Lloyd's remarks (Jan. 1, p. 30) concerning mallet finger. I think it is important, however, to x-ray all mallet fingers, as the line of treatment should differ according to whether or not a small fragment of bone is avulsed from the base of the dorsum of the distal phalanx. If there is such bone involvement, then it is worth while immobilizing the finger in the position usually recommended—i.e., 90 degrees flexion at the proximal joint, with the distal joint hyperextended. One month's fixation is sufficient, by which time clinical union is obtained.

Should there be no bone involvement, then the best results are obtained by non-fixation. I usually instruct the patient to hyperextend the distal joint by pressure of the affected finger against the thumb. This can be carried out on multiple occasions throughout the day, giving an end-result of loss of not more than 10 degrees extension at the terminal joint. Very few people find this to be any disability whatever, and the majority are able to work from the beginning. Local application of ung. "iodex" and methyl sal. helps to relieve the pain at the affected site during the first few weeks. It takes several months before the final result can be assessed.

Plaster fixation does not give results as good as the above method, and quite often the patient is unable to continue at work during the

immobilization. Attempts at suturing the torn extensor may lead to loss of flexion at the distal joint or to septic complications leading to disabilities which are far greater than the results obtained by the above regime.

I would also give strong support to the treatment of simple ganglia recommended by Mr. Eric Coldrey (Jan. 1, p. 32). Treatment by aspiration and injection of sclerosing fluid is in my opinion definitely contraindicated and shows a lack of appreciation of the pathology of the condition, as there is always a communication between the ganglion and either a tendon sheath or joint. Obviously injection of sclerosing fluid into either of the latter could be very dangerous.

The complete excision of ganglia may also be dangerous in inexperienced hands owing to extensive ramifications of the ganglion amongst important anatomical structures. The treatment should be as Mr. Coldrey states: (1) attempted dispersion by pressure of the thumb, or (2) insertion of a tenotome and dispersion if the first method is unsuccessful. Recurrence may occur whatever method is used; it behoves us therefore to use the simplest method possible. Recurrence following puncture by the tenotome is not an indication for surgical excision. The only indication for surgical interference is inability to disperse the swelling following puncture, and in this case it is usually found that the tumour is not a simple ganglion at all but is often a fibroma, which one may find impossible to differentiate from a very firm ganglion.—I am, etc.,

West Bromwich

J. H. KIRKHAM.

SIR,—In his letter questioning the value of conventional treatment for mallet finger Dr. W. J. Lloyd (Jan. 1, p. 30) has made a useful point. I am not ashamed to admit that my own results are depressing, and that of six cases operated on during 1948 only one regained normal extensor function. I agree entirely with Dr. Lloyd that better and far quicker rehabilitation is to be obtained by returning to work without treatment of any kind, and that treatment is indicated only when a special skill demands an attempt to restore full function in the distal segment of the finger.

Perhaps more important than the immediate subject, however, is the general issue involved. In dealing with any non-disabling condition it is often of value to ask oneself whether prolonged treatment, which inevitably makes it necessary to cure the complications caused by that treatment, is really worth while when measured against the advantages of a rapid return to activity.—I am, etc.,

London, W.1

DAVID LE VAY.

Self-administered Pneumothorax Refills

SIR,—I have just read Dr. Philip Ellman's letter on self-administered pneumothorax refills (Oct. 16, 1948, p. 723). I have never heard of a lay person administering his own refills, but I have reason to believe that this is not an uncommon procedure among medical practitioners suffering from tuberculosis. While personally I have never encountered any such practitioners, I heard of some such half-dozen while in Australia early in 1948. This tempted me to conduct my own refills. I have since done this on frequent occasions.

The procedure is amazingly simple and devoid of difficulty or discomfort. The assistance of a nurse is not required provided the apparatus incorporates a three-way tap instead of the usual clips. This tap has three positions connecting thus: (1) outlet bottle to patient, (2) patient to manometer, and (3) both outlet bottle and manometer cut off or neutral. The bottles are set up with the water-containing bottle elevated, so that when the tap is turned "outlet to patient" air will flow from the air-reservoir bottle. First the tap is in "neutral." Then I prepare the chest, and, having drawn a few ml. of local anaesthetic into a syringe with a fine needle, I raise a bleb over an intercostal space laterally and high in the axilla. The pneumothorax being left-sided, it is necessary to stand up during the procedure, the left shoulder being abducted to ninety degrees, the elbow flexed to forty-five degrees, and the palm of the hand resting on the occiput.

A gauge 22 needle is then fitted to the syringe and the intercostal space penetrated. The space is entered with the needle either perpendicular or oblique to the skin surface, depending on one's ability to conduct this manipulation with one hand. Actually an oblique penetration is simpler but requires a longer needle. When the pleural

space has been entered a few bubbles of air drawn back into the syringe ensure a patent needle. The left hand can now be freely used for any manipulations. The syringe is now disconnected, leaving the needle *in situ*, the rubber outlet tube from the air-containing bottle is connected to the needle, the tap turned to "patient-manometer" position, and a reading obtained. Using a fine needle (gauge 22) I have never had difficulty in establishing a "free swing"; no needle blockage has occurred, nor has a second attempt ever been necessary. After a free swing is established and the reading noted, the tap is turned to the "outlet bottle to patient" position. Siphonage into the air-holding bottle results and the pneumothorax refill is now in process.

This procedure is simple and painless, and takes under fifteen minutes for a 600-ml. refill from start to finish. It can be carried out unaided, using one hand only—in my case the right, as I have a left-sided pneumothorax.

I would like to mention the use of a spirometer in controlling refills. This calls for the co-operation of a radiologist in the first instance, with the simultaneous taking of radiographs and spirometer readings. These can be correlated for almost any patient with a unilateral pneumothorax in a short time. In my own case a vital capacity of 1,600–1,800 ml. indicates satisfactory radiological collapse, while a reading of about 3,300 ml. indicates almost total re-expansion, with difficulty in entering the pleural space. This of course does not displace routine films but is nevertheless a helpful guide, as spirometry is both convenient and simple compared with frequent films and screenings.—I am, etc.,

Auckland, New Zealand.

LAURIE GLUCKMAN.

Syringe-transmitted Jaundice

SIR,—I feel that Dr. Donald D. Brown's letter (Dec. 25, 1948, p. 1119) must be answered, and for this reason I would like to present the following facts for his consideration.

1. Much higher rates of hepatitis than that described by me (November 27, 1948, p. 938) have been reported as occurring in V.D. clinics. These rates occurred irrespective of outbreaks of epidemic infective hepatitis and were arrested by proper sterilization and supervision of syringe technique. Very low rates of hepatitis have continued in the clinics concerned, irrespective of the incidence of jaundice in the population.

2. My cases were not divided into infective hepatitis and syringe-transmitted hepatitis. Such a division is admittedly clinically impossible. It should, however, be pointed out that no outbreak of infective hepatitis occurred in this area at or about the dates concerned (April to September, 1947). A survey of the literature reveals only one description concerning the incidence of hepatitis during an epidemic of the infective type. This was in Leicestershire, and the incidence was much less than 1% of the population.

3. For at least ten years jaundice has been by far the commonest complication of the antisyphilitic treatment given in this clinic.

4. During the period reviewed the incidence of hepatitis in male patients suffering from gonorrhoea was 4%, when these patients were followed up for four months. These patients made about 14 visits during the four months and shared the waiting-room with syphilitics under treatment and incubating hepatitis. They received one intramuscular injection of penicillin, and blood for W.R. was taken on five occasions. The W.R.s were performed with a common syringe and needle, washed in running tap water between each blood-taking and boiled once a day only.

5. No records of the incidence of hepatitis in the families of these men is available, but, as Dr. Brown will understand, a fair proportion of the females attending the clinic were wives, sweethearts, consorts, mothers, and daughters of male patients. The incidence of jaundice at the female end of the clinic for all syphilitic patients attending during the reviewed period was 2% only, when these women were followed for one year. An investigation of sterilization arrangements on the female side of the clinic revealed these to be good—the only loophole to a possible syringe transmission lying in the use of a common bismuth syringe boiled once daily.

6. No case of hepatitis occurred in the clinic staff, although many of these had "long conversations" with males incubating and suffering from hepatitis.

7. Three months after the introduction of controlled boiling and with better supervision the incidence of jaundice in this clinic has shown a rapid decline.

I trust that this information, in conjunction with the very exhaustive review of the literature provided in the leading article in the *Journal* of Dec. 18 (p. 988), will confirm Dr. Brown in a full appreciation of the facts in both theory and practice. If cases of hepatitis are to occur in any number in any type of

clinic where multiple injections are being given two stages are necessary: (a) the introduction of a syringe-transmissible virus by a patient, and (b) its subsequent propagation by inadequately sterilized syringes. So Dr. Brown is too modest (I cannot believe him too lucky, as I am sure the syringe-transmissible virus of hepatitis has not missed Bristol in its general itinerary). If the incidence of hepatitis in the Bristol V.D. clinic is under 1%, Dr. Brown has only his "best laid schemes" to thank.—I am, etc.,

Newcastle-upon-Tyne.

R. S. MORTON.

Nephritis in Textile Workers

SIR,—Dr. G. Herdan (Dec. 18, 1948, p. 1083) makes justifiable criticism of some of the statistics in Professor Platt's article (Nov. 15, 1947, p. 771), but it seems that Professor Platt intended to indicate broad trends, and he has stated emphatically that his figures prove nothing.

Dr. Herdan's own figures appear to be at fault. In his first table the number of male deaths from nephritis for ages 16–24 (females is presumably a misprint) should read 220 per year and not 462 (*vide* Registrar-General's *Decennial Supplement*, 1931, Table 4A). In his second table there seem to be errors in the lowest and highest age groups, presumably because deaths at 65 and over have been related to the wrong populations at risk. This should read as follows:

Deaths from Nephritis per 100,000 at Risk in Each Age Group*

	16	25	35	45	55	65	70+
Textile workers	10	14	20	111	153	433	555
All males	7	9	18	49	108	219	389
Social classes III and IV	7	9	18	46	102	207	389

* Taken from the Registrar-General's *Decennial Supplement*, 1931.

It will be seen that the excess of mortality from so-called nephritis of textile workers over all males and over males in social classes III and IV occurs in all age groups, but the differences in the three youngest groups are small.

There is some danger in making assumptions from such crude data, which represent the opinion of general practitioners who often cannot verify their diagnoses either by necropsy or special investigation. For example, Dr. Herdan states: "It would thus seem—adopting Professor Platt's theory of essential hypertension as a hereditary disease for textile workers—that such workers in addition to being through their hereditary make-up prone to malignant hypertension are also at an increased risk of falling a prey to renal disease through environmental factors." These assumptions may be quoted and requoted until they become established facts in the minds of many. There has already been a tendency to accept renal disease of textile workers as a definite entity caused by social or occupational factors. This does not deny the enormous value of the Registrar-General's figures, but in many instances they should be used as pointers to further investigation and not as proving the existence of an occupational or social disease.—I am, etc.,

Manchester.

RICHARD SCHILLING.

** Dr. Schilling correctly refers to a misprint. Dr. Herdan's letter was not at fault.—ED., *B.M.J.*

Spinal Analgesia and Caesarean Section

SIR,—In my letter about classical caesarean section (Nov. 13, 1948, p. 877) I incidentally expressed preference for spinal analgesia, which has called forth opposition. Dr. C. D. Sanders (Nov. 27, p. 959) says that increased uterine contractions endanger the life of the child. This is not so. Mr. D. Stanley-Jones (Dec. 25, p. 1121) suggests that there is danger of sudden death of the mother by bleeding into the uterus due to paralysis of vasomotor control, omitting the action of the powerful uterine muscle, the tone and contraction of which are increased if anything—Dr. Sanders would agree with this. I actually advise spinal "percaïne" for the very reason that haemorrhage is reduced, as in other pelvic operations, and, incidentally, shock, owing to the abolition of afferent sensory impulses from peritoneum and viscera.

I have a feeling that neither of these critics is well versed in the subject. Mr. Stanley-Jones, for example, does not seem to have followed the discussion in the *Journal* (November, 1945–April, 1946)

following the publication of an article by Dr. Louis Resnick (Nov. 24, 1945, p. 722), and a discussion at a meeting of the Section of Obstetrics and Gynaecology at the Royal Society of Medicine (reported in the *Journal* of April 5, 1947, p. 463). Dr. Resnick gave two series of cases totalling 394—137 caesarean and 257 operative vaginal deliveries—as well as a series of other gynaecological operations amounting to 1,500, all under spinal analgesia (heavy "nupercaine"), with no mortality. In your issue of Feb. 2, 1946 (p. 181), Mr. Rufus Thomas wrote to confirm Dr. Resnick's findings and to add his own experience of 2,000 cases—200 caesarean sections and others, including forceps deliveries, 15 ruptured ectopic gestations, therapeutic abortions, large ovarian cysts complicating pregnancy, etc., with not a single fatality. Criticisms by Drs. Helen Alcock (Dec. 8, 1945, p. 818) and Loftus Dale (Dec. 8, 1945, p. 819) were answered by Dr. Resnick (Jan. 26, 1946, p. 145), who said that for a long time he had been prejudiced against the use of spinal analgesia, being deterred by the "risks," largely theoretical, which were advanced, usually by armchair critics. The dangers, complications, and methods of meeting them were fully discussed, and it would only be a waste of time to attempt to recapitulate them now. Another surgeon, Mr. W. C. Spackman (April 6, 1946, p. 546), told of 3,000 gynaecological cases with only two deaths (in elderly patients with large ovarian cysts). Dr. James Ross (Dec. 8, 1945, p. 819), detailing his special technique, gave caesarean section as a main indication for spinal analgesia.

I quote these surgeons because of the large experience they can adduce in this matter. I have had experience of spinal analgesia for the last twenty years or more in a fair number and in a fairly wide variety of surgical cases with the utmost satisfaction. My practice is to use light percaïne (or nupercaine) for every major operation below the umbilicus, for any age, unless there is some very definite contraindication. These contraindications become less and less as one gains experience in the judgment of dosage and confidence in one's technique, including pre-medication, position of patient on the table and afterwards in bed, etc. I may say that my chief contraindication has been where a patient has been scared by hearing of some friend's unfortunate experience with a badly given spinal analgesic and her report that "she felt everything"; or, again, where some silly member of the nursing staff has a personal prejudice and in some way, perhaps indirectly, lets the patient know about it—another example of the need for good team work.

Operating under a good spinal analgesic is very satisfactory for the surgeon, and it is very pleasant at the end of the operation to tell the patient that the job is finished and to hear his surprise and also his expression of feeling very well indeed. It seems to me very reasonable to anaesthetize as nearly as possible only that part of the body on which one has to work. If a local anaesthetic will do, so much the better; but there is no doubt that for lower abdomen and pelvic work spinal analgesia is the thing. I pointed out in a letter some years ago that every ship surgeon should be master of the technique, giving him the advantage of perfect operating conditions where no skilled anaesthetist is available.—I am, etc.,

Chiswell, Essex.

N. BEATTIE.

The M'Naghten Rules

SIR,—Dr. Frederick Dillon (Dec. 18, 1948, p. 1083) may lead less experienced men astray unless it is pointed out that the presumption of law is that a man is innocent until he is proved guilty. His procedure may apply where the prisoner intends to plead guilty and to prove extenuating circumstances, or where, with a plea of guilty, such circumstances are capable of proof irrespective of the prisoner's attitude to them. Otherwise the witness on either side who goes into court assuming that the prisoner committed the crime but that there is a good explanation of why he did will soon find himself in trouble.

The prosecution undertakes to prove that the prisoner, and no other, did a deed which is criminal. It may be that they succeed in proving he did the deed and fail to establish criminality, or that they fail to prove he without reasonable doubt did a deed certainly criminal. In either event the trial ends there: the prosecution have failed to set up a case demanding answer. Only when both requirements are satisfied is any answer required; and that answer may either show the prisoner did not without reasonable doubt do the deed, or that the deed was not certainly criminal, or both. In either event acquittal follows. Any accused person has therefore a double defence: (1) the prosecution may fail to establish its case, and (2) the defence may, if the case is established, break it down.

It is, perhaps, fortunate for the prisoner that the zealous medical witness for the defence has no opportunity to say, "Of course he cut his wife's throat, but I can tell you why he did, and it is not his fault," until the prosecution has satisfied the judge and jury that

there is a strong probability he did, whether it was his fault or not. Dr. Dillon starts off by assuming that there is a case to answer, which, although it is the opinion of experienced legal advisers of the police and of the Director of Public Prosecutions before the case is brought before a court, and of the court of first instance before trial by judge and jury, is not the opinion of the trial court until or unless they are themselves, by evidence actually brought before them (although earlier adduced elsewhere), satisfied that there is a case to answer.

Dr. Dillon's strictures on prison medical officers are certainly not borne out by such experience as I possess. His proposals again contravene the prisoner's rights, for, although the prosecution is bound to disclose all its evidence in the depositions in the lower court in order that the defence may know what the case is they may have to answer, it is quite open to the defence, and a frequent practice, to plead not guilty and reserve the defence for the trial court, when the investigations of the visiting psychiatrist can be kept as a surprise packet for the medical witness for the prosecution under cross-examination before the medical witness for the defence is allowed in the court at all. If this fails to break down the prosecution, the psychiatrist can then himself have a second try in his evidence for the defence.

The prison doctor is not entitled to be informed of what the defence has ready for him in cross-examination any more than any other prosecution witness is, and defence counsel frequently make use of denial to witnesses of advance information such as Dr. Dillon wants them to have. His suggested alteration of legal, not medical, practice would, by preparing a material witness for cross-examination, increase the chances of conviction; and no matter how the medical or psychiatric rules on the subject are expressed the medical witness for the defence would be left to explain how it is not the prisoner's fault, against the prosecution witness who has said it is.

Medical jurisprudence, or forensic medicine, was not in my time a subject of much interest to most students; but it is essential for any medical man who wishes to do his duty in any court to realize that it is, as the second and better name implies, essentially forensic. If he is not prepared to learn the rules of cricket before he goes on to the field, his wisest course, and that in the best interest of his patient, is to stay on his own golf course, where he can play singles to his heart's content, and keep out of the courts, where he is expected to be one of a team.—I am, etc.,

London, S.W.6.

C. T. NORRIS.

Master Minds

SIR,—I note in your issue of Jan. 1 (p. 23) reference to a report of a speech made by me at a recent meeting at Hendon. It is to be deplored that you should publish such references to myself without consulting me to see whether or not the report in question was in accordance with what was said. The only part of the report that had any reference to me at all was the reference to the fact that patients could attend a doctor's surgery at certain hours of the day; the rest of what was reported was said by other speakers and not by me.

I have always held the view that the medical profession has nobly undertaken the arduous duties of a public service, but in honesty I have been compelled to refer to the lack of organization in the general practitioner service. Believe me, I made no reference to a master mind, nor do I think that there is a master mind in the Service; for it to be successful it must be a co-operative service, each one playing his proper part.

The paper in which the report appeared is, of course, definitely opposed to my political views, but if the notes of the reporter were examined it would be found that through the whole of my speech I made no reference at all to politics.—I am, etc.,

House of Commons

FRED MESSER.

* In its account of the meeting of the North-West Branch of the Socialist Medical Association the *Hendon Times* reported Mr. Messer's speech in forty lines of print. In view of the British journalist's well-earned reputation for accurate reporting we did not consider it necessary to consult Mr. Messer about the accuracy of a strictly objective report free from comment.—Ed.. B.M.J.

POINTS FROM LETTERS

Procaine Penicillin

Dr. DAVID WHEATLEY (Twickenham, Middlesex) writes: Dr. T. David Lambert (Dec. 25, 1948, p. 1119) has recorded some of his experiences with this preparation in general practice. This prompts me to mention an alternative method of penicillin administration which I have used for some time past in general practice. I refer to the administration of pure crystalline penicillin by subcutaneous injection as has been advocated by Hoffman (*J. Lab. clin. Med.*, 31, 1165). I have administered penicillin by this method to over 50 cases and have not encountered any case of pain or local reaction at the site of injection, and my cases have included many children, amongst them a baby of six months. These cases included pneumonias, acute otitis media, whitlows, carbuncles, etc., and puerperal mastitis. In all, the results were considered very satisfactory by physician and patient alike and compare favourably with Dr. Lambert's results with procaine penicillin. The dosage usually employed was 200,000 units dissolved in 1 ml. of sterile water every 24 hours for four days. The debatable theoretical basis for this particular dosage scheme does not come within the scope of this communication. In conclusion I would suggest that the extreme ease and simplicity of the subcutaneous injection of crystalline penicillin make it a very convenient procedure in general practice.

Rhinitis Caused by Friedländer's Bacillus

Dr. H. FARRAG (Cairo) writes: The following case report may be of interest. A patient 49 years old was suffering for the last 20 years from chronic persistent rhinitis associated with sneezing, mild cough, and absence of the sense of smell. . . . A swab was taken from the nose and examined bacteriologically. The material proved to be a pure culture of Friedländer's bacillus (*Klebsiella pneumoniae*). An autogenous vaccine prepared in the usual way (bacterial suspension killed by heat at 60° C. for one hour and 0.5% phenol added as preservative) was prepared, but gave no result. Another method was tried: the organism was grown in ordinary broth for ten days at 37° C. to allow complete disintegration. The culture was filtered through a Seitz filter, and the filtrate was tried locally in the form of a nasal spray twice daily after diluting it with three times its volume of sterile saline. This treatment proved excellent and relieved the patient within a week of application. It was continued for one month, and the patient was apparently cured. Freshly prepared filtrate of the lysed organisms by prolonged incubation seemed to be the only effective method to maintain the antigenicity of the organism unaltered, as it was found that heating or the addition of any chemical preservative to the filtrate destroyed its effect.

Prolonged Gestation Period

Dr. S. M. WELLS (Valparaiso, Chile) writes: Your account of "The Longest Gestation Period" (Nov. 6, 1948, p. 840) recalls a case of mine details of which were published in *Guy's Hospital Gazette* (Nov. 6, 1948, p. 299). This was a woman of 36 whose last menstrual period was on May 5, 1947. On July 26 the size of the uterus corresponded to a pregnancy of between two and three months. Her confinement was expected on Feb. 9, 1948, but she was not delivered until April 3. The child was a boy weighing 4.05 kg. (nearly 9 lb.). We now know that conception usually takes place fourteen days before the next expected period, the day on which ovulation is supposed to take place. Estimating, however, the length of pregnancy as it is still usually done, from the first day of the last period, this particular pregnancy lasted 334 days, i.e., 54 days above and beyond the normal 280 days.

Plain Words on Dimensional Lesions

Dr. EDWARD S. STERN (Warwick) writes: I protest against the use of the phrase "space-occupying lesion" instead of morbid swelling. It is physically impossible for a lesion not to occupy space. I would write more on this subject but cannot, owing to the space-occupying lesions on my fingers caused by chilblains.

Whooping-cough and Measles

Dr. C. L. MALHOTRA (Jubbulpore, India) writes: Dr. Frederick Rothenburgh (Nov. 6, 1948, p. 839) has mentioned that a sudden attack of pertussiform cough with heavy fits similar to whooping-cough may be a precursor of measles. That may be so, but I have seen the reverse. Attacks of whooping-cough, in no way distinguishable, during which the child in fits of coughing hugged the nurse for support, have followed a moderately severe attack of measles. The "whooping-cough" was relieved by two or three days' use of codeine cough mixture. The measles was picked up in school when it was prevalent, and there was no whooping-cough about.

Obituary

Dr. THOMAS ROGER REES died on Nov. 21, 1948, at the age of 56. A native of Alltwn, near Swansea, and the son of a well-known Nonconformist minister, he served in the R.A.M.C. in Mesopotamia in the 1914-18 war. He received his medical training in Cardiff and at St. Bartholomew's Hospital, qualifying in 1922. After a period as house-physician at the Cardiff Royal Infirmary he went into general practice in Cardiff. There he continued in active and busy practice until his last illness, though he had known for many years that his health was undermined. Throughout his time in Cardiff Dr. Rees had participated with keen interest in B.M.A. affairs, being a member of many of the local committees, including the Local Medical War Committee; he was chairman of the Cardiff Division in 1944-5. During the recent war he became a member of the Cardiff City Council, and more recently he served on the Cardiff Hospitals Management Committee, and as vice-chairman of the Cardiff Executive Council under the Health Act. He also took a lively interest in political affairs and sport, and was a valuable member of any committee, ever ready to maintain his point of view. He had a keen insight and a sense of humour which made him a delightful companion. Dr. Rees was very loyal to his patients and continued to attend them when he was not really fit for any of the work of general practice. Many of us regret the passing of "Tom," as he was familiarly known to us, and will miss his cheery laugh and high spirits, his personality and companionship, as well as his regular attendance and help at committees. He leaves a widow, to whom we extend our sympathy.—J. W. T. T.

Dr. WILLIAM BLAYNEY, son of Alexander Blayney, of Cushendall, died at his home in Watford, Hertfordshire, on Dec. 4, 1948, at the age of 71. He was educated at St. Malachy's College, Belfast, and entered the Royal Irish Constabulary in 1899. He was county inspector for Clare at the time of the disbandment of the Royal Irish Constabulary in 1922. He served in the 1914-18 war as assistant provost marshal of the 57th Division, and was for a time musketry instructor at the R.I.C. Depot in Phoenix Park. He studied medicine at St. Thomas's Hospital, and qualified M.R.C.S., L.R.C.P. in 1927 at the age of 50. Dr. Blayney practised in Harrold, Bedfordshire, until his retirement in 1943. He was highly esteemed in the district, and his thoughtfulness and kindly nature made him many friends. Both he and his wife took a very active part in village affairs, and among other activities Dr. Blayney was chairman of the Carlton and District British Legion for a number of years. He was a delightful companion, gifted, highly intelligent, and well read. His brothers were the late Mr. Alexander Blayney, a distinguished Dublin surgeon, and Dr. N. J. Blayney, of Portlaoighaise. He married in 1917 Miss Mary Beveridge, a daughter of John Beveridge, town clerk of Dublin, who survives him with four sons and three daughters.

Dr. JAMES MURDOCH MACKAY, who died at Cheltenham on Dec. 28, 1948, had a distinguished career in the West African Medical Service. He was a student of Glasgow University, and graduated M.B., Ch.B. in 1915.

A colleague writes: The death of J. M. Mackay at a comparatively early age was a direct outcome of his service in the first world war, when he was severely gassed. He served with much distinction, being awarded the M.C. and mentioned at least twice in dispatches. It was characteristic of his courage that, though granted a pension at the time, he gave this up voluntarily and proceeded to join the West African Medical Service. Here he served respectively in Sierra Leone, in Nigeria as A.D.H.S., and on the Gold Coast, where he became director of the Health Service. On the outbreak of the second world war, in spite of indifferent health, he organized and commanded the Gold Coast Regiment Field Ambulance (R.W.A.F.F.) and went right through the Abyssinian campaign. Later, taken gravely ill while on troopship duties, he had to be invalided out, and he returned again to his civilian administrative post in the Gold Coast, which he relinquished in 1945. Not content with retirement, he then joined the Ministry of Pensions staff, and was actively employed right up to his last illness. Mackay was over six feet in height and had a fine imposing presence. He was the most loyal of colleagues as well as an able administrator. He never let anyone down. His modesty, lack of self-seeking, and his sense of justice and fair play made him what he was, one of the best medical officers it was possible to serve under. He never forgot to interest himself in his juniors and to encourage them in their work. He was no "yes man" and would fight for right, if necessary at the very highest level. He was a worthy son of his Highland ancestry, of which he was

Painless INTRAMUSCULAR INJECTIONS

e.g. of PENICILLIN, LIVER EXTRACTS,
ARSENO-BENZOLS, BISMUTH, etc.

Many substances create some pain on intramuscular injection. Novutox injected at the same time will prevent this pain.

Most substances are compatible with Novutox, which is also non-destructible to penicillin during the time that the latter is undergoing absorption.

Mixtures with Novutox should be made
immediately before use ONLY.

NOVUTOX

Self-Sterilising
Local Anaesthetic

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinotoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

SPARKLING CLEANLINESS

Radiographers know that they are assured of exceptional latitude, sparkling cleanliness and excellent contrast when they use Ensign STANDARD X-ray film. The difficulties of chest radiography are manifold. Geometrical distortion by the size of the tube focus, physiological movement and grain of the intensifying screen make the use of Ensign Standard essential. Standard Exposure times can be varied without impairing the high quality of the finished radiograph. Ensign STANDARD is a film of normal speed that will give you the finest possible definition even when dark room conditions are not too favourable.

are chilblains foreign to your practice?

In Britain now the 'chilblain season' is focussing attention on calcium therapy and on the simple but efficient treatment that Ostocalcium Tablets provide. But neither weather nor whereabouts limit the use of Ostocalcium.

Allergic skin diseases, migraine and even the 'general debility' met with in general practice the world over—these are typical of the conditions in which Ostocalcium is used to good purpose. Ostocalcium is also valuable, of course, during such times as pregnancy and lactation when the need for calcium is increased. And when you prescribe Ostocalcium the patient receives not only calcium itself but also sufficient vitamin D to ensure proper assimilation of the mineral.

In containers of 50 and 100 tablets.

*This size available only in the British Isles

Each tablet provides 125 mg. calcium and 500 i.u. of vitamin D

Research Laboratories: Manufacturers of medical products and (Glaxo) Glaxo Laboratories are represented by associate companies or agents in almost every country in the world.

ADAPRIN TABLETS *for the prevention and treatment of* **CHILBLAINS**

One ADAPRIN tablet taken three or four times daily usually effects relief within a short period and recurrence of the symptoms can generally be prevented by the administration of one or two tablets per day.

ADAPRIN is a combination of the Vitamin K analogue (Acetomenaphthone 10 mgm.) and Vitamin PP (Nicotinamide 50 mgm.) in tablet form, suitable for the effective treatment and prevention of chilblains. ADAPRIN tablets are non-toxic and can be of additional value in counteracting any deficiency of Vitamin K or Vitamin PP in the patients' diet.

Detailed information available on request.

BELLADENAL

**Antispasmodic .. Anticonvulsive
Sedative**

BELLADENAL combines the central sedative action of phenobarbitone with the peripheral antispasmodic action of the total laevorotatory alkaloids (Bellafoline) of Belladonna leaves. Bellafoline is only half as toxic as atropine in doses which are therapeutically equivalent in their effect on the parasympathetic.

Each tablet of Belladenal contains:

Bellafoline	0.25 mg.
Phenobarbitone	0.05 Gm.

The components of Belladenal act synergistically with each other so that a powerful antispasmodic and sedative effect is obtained with comparatively small doses.

Full particulars and samples on request

SANDOZ PRODUCTS LIMITED
134, Wigmore Street, London, W.1

CELLON LABORATORIES LTD.

The following tested preparations are available for prompt delivery:—

CELETANE (REGD.) — MEDICATED (LETHANE) HAIR OIL—N.W.F.

The modern insecticide for eradication of head lice (Pediculosis Capitis), as employed by many Medical Officers of Health, etc.

BENZELIA (REGD.)—BENZYL BENZOATE EMULSION—25%

A well-established preparation for rapid eradication of scabies within 48 hours. Also supplied in form of vanishing cream.

OLEOCIDE (REGD.)—OLEO-SULPHONAMIDE

This valuable preparation is a marked advance in Sulphonamide Therapy. Ensures rapid relief of ulcers, impetigo and other streptococcal infections of the skin; first and second degree burns—broken or unbroken.

CELOZENE (REGD.)—ANTISEPTIC

A powerful non-toxic, non-irritant antiseptic of great value for wounds and cuts, having a Rideal Walker value of 4.0. A special grade can be supplied for sterilising instruments.

SKLEN (REGD.)—PLASTIC BANDAGE REMOVER (NON-INFLAMMABLE)

A solution for dissolving adhesive of plastic bandages enabling easy removal of plaster and subsequent cleansing of adhesive remaining on the skin.

SPASTIC DYSMENORRHOEA ?

MENOVO
indicated!

A CAUSAL AND SYMPTOMATIC THERAPY

"MENOVO" combines the causal antispasmodic effect of Ephedrine and Belladonna with the symptomatic analgesic action of Phenacetin and Codeine and the sedative effect of Bromisovalerylurea and Carbromal. The preparation is of proven clinical value in the treatment of uterine spasms and other disturbances associated with Spastic Dysmenorrhoea.

ACTIVE INGREDIENTS

Ephed. Hydrochlor B.P.	0.36%	Codein Phosph. B.P.	0.63%
Ext. Bellad. Sicc. B.P.	0.72%	Bromisovalerylurea	3.12%
Phenacet B.P.	37.50%	Carbrom B.P.	9.18%

TOTAL WEIGHT OF TABLET, 8 Gr

CPL

so justly proud. Not only will he be missed by the West African Medical Service and those he served under in the recent war, and by the Ministry of Pensions, but by his old comrades of the D.C.L.I., to whom he was regimental M.O. in France. To his children and to his widow our deep sympathy must be extended.

Dr. RICHARD CECIL HUTCHINSON died on Christmas morning at his home in Worthing following a second coronary occlusion. A Lancashire man, he graduated M.B., Ch.B. with honours at Manchester University in 1910 and proceeded M.D. ten years later. In 1913 he took the D.P.H. After acting as house physician at the Manchester Royal Infirmary and at the Brompton Hospital, he was appointed to the staff of the King Edward VII Welsh National Memorial Association, being in charge of the Carmarthen and Cardigan Area. Two years' active service in France followed with the rank of captain, R.A.M.C. He was then medical superintendent successively of the Baguley Sanatorium, Manchester, the Royal National Hospital, Ventnor and the Tor-na-Dee Sanatorium, Banchory. In 1928 Hutchinson moved to Worthing where he spent twenty busy and fruitful years. Quiet and kindly in demeanour, a thoughtful and thorough clinician, he was at once a success in private practice. His long experience of chest work stood him in good stead. He was quickly recognized as possessing special knowledge and skill in that branch of medicine, and his services became of increasing value alike to his patients and to his professional colleagues. It was not long before he was overworked, and he never spared himself. During the war years he gave fine service to the Royal Sussex County Hospital, working long hours in the out-patient department and then, in the winter months, driving home twelve miles in the blackout. He was subsequently elected a life governor of the hospital. Dr. Hutchinson had served the Brighton and Sussex Medico-Chirurgical Society as financial and as literary secretary and had he lived would soon have been its president. He joined the B.M.A. in 1913, was an active member of the West Sussex Division, and had completed three years on the executive committee. A keen sportsman and country lover, Hutch' was equally happy with rod or with gun. Last August in company with the writer he caught his last salmon from a boat and shot his last grouse from a butt. His family life was happy, and he is survived by his widow, two married daughters and a son. Shortly before his death he had after a lengthy search found a farm in West Sussex for his son, demobilized from the R.E. There, within reach of Worthing, it had been his hope to live and to continue his work but at lessened pressure.—D.H.

Mr. T. Twistonlong Higgins writes: Hutchinson enjoyed natural gifts of observation, critical insight, and shrewd judgment which made him one of the most able doctors I have known. His special skill and experience in chest disease brought him a well deserved reputation, and in any company of physicians he could claim distinction. But not for this alone will he be remembered by all who knew him. Professional prowess was not foremost in the minds of those who gathered from far and wide at Christ Church, Worthing, in the wintry sunshine to do honour to his name. For each of us in that impressive congregation a personality had passed to whom, in our several ways, we owed a debt which could be acknowledged but never repaid. For above all "Dick Hutch" was a very gallant gentleman who gave of himself to others without stint or question. Such men are rare. Their lives are an inspiration, and when they no longer march with us our sadness is tempered by thankfulness that we have been privileged to know them on the way.

Dr. A. F. Sladden writes: I was intimately associated with Hubert Phillips (Jan. 1, p. 35) for the past forty-five years. His death has taken from Port Talbot and South Wales a most notable and beloved doctor. He will be remembered by his contemporaries at Oxford and St. George's Hospital, where as a student he had a distinguished career and impressed his personality on a wide circle of friends. He could undoubtedly, had he wished, have established himself as a consultant in London but chose instead to exercise his great gifts in his native country, and who shall say that he took a wrong course? Phillips was a Pembrokeshire man well versed in the history and customs of Wales, and spoke Welsh with facility. His broad education and experience of a wider world, however, made him a cosmopolitan free from any narrow nationalism. He was by inclination a surgeon, but his work as a physician was quite outstanding, and with his gifts of sympathy and untiring devotion he manifested all the qualities desirable in a general practitioner of the very best type. As a surgeon he was attached to the Port Talbot General Hospital where his colleagues confidently referred their surgical problems to him. In consequence a heavy toll of operating was added to his other labours but he preferred it so in spite of the excessive

burden involved. There is little doubt that his continuous work latterly injured his health but he refused to relax. In spite of his arduous professional life he found time to engage in other interests. He was gifted artistically, and with pencil and brush produced a series of coloured cartoons with grotesquely humorous figures and faces which were the delight of his friends. His garden, and particularly his roses, were a constant joy to him, and in later years he became an enthusiastic and proficient photographer. Phillips was a good conversationalist and a man of wide intellectual interests. His scientific training had not obscured for him the spiritual and philosophical aspects of life, and he was happy in being able to realize for himself a satisfactory synthesis between science and religion. Hubert Phillips was the elder son of the late Canon Phillips, of Newport, Pembrokeshire, and he married Irene, daughter of the late Canon I. Jewell Williams of Llanwenarth, Monmouthshire. He had one son, Dr. Geoffrey Phillips, now practising at Ware, and the sympathy of all his friends goes out to his widow and son. They may well be proud of his memory.

Dr. J. B. Horgan writes: It is nearly forty years since I first met Lionel Colledge (Jan. 1, p. 34) at the hospital at Golden Square, where I was acting house-surgeon. In after years I was a welcome visitor at the clinics where he worked and I often profited from his counsel and co-operation in difficult cases. I would like therefore to express a few words in gratitude to his memory and of condolence with his British colleagues from the other side of the Irish Sea. Colledge had a stern appearance and a reserved manner which however, hid a gracious personality with a subtle sense of humour. He was extremely modest of his high achievement in the specialty which is so much the poorer for his passing.

Medico-Legal

ANAESTHETIC EXPLOSIONS

[FROM OUR MEDICO LEGAL CORRESPONDENT]

Explosions in the operating theatre are fortunately rare in the United Kingdom, largely because its damp atmosphere is unfavourable to the accumulation of static electricity which constitutes such a problem in the dry air of the United States and other countries. A fatal accident of this kind however, took place in November, 1948, in the Southend General Hospital when during an operation the anaesthetic apparatus was wrecked, the patient mortally injured, and the anaesthetist, Dr. Noel Vincent, momentarily stunned. Dr. Vincent said in evidence at the inquest¹ that the explosion had been reported to the British Oxygen Company, a representative had visited the hospital, and the apparatus had been taken to the works and reconstructed to simulate its condition before the accident. The report stated that a leakage in the explosive mixture was present, and the source of the ignition had not been ascertained. The leakage had been found between the breathing-bag and the bag mount. The apparatus had been modified at the hospital, the concertina type of breathing-bag being superseded by a length of corrugated rubber hose and a new breathing-bag. The coroner said that the evidence showed death to have been due to collapse of the lungs as a result of pulmonary shock consequent on the explosion. He found that there was no criminal liability and expressed his sympathy with the relatives and with Dr. Vincent that such an accident should befall him after so many years of experience.

The newspaper report does not say whether any electrical machinery was in use at the time of the explosion, presumably if it had been the company's report would have mentioned it. A high temperature generated in a theatre by central heating may of course reduce humidity to such an extent that static current may be accumulated in apparatus if this is not earthed, and then even a small spark may conceivably ignite an inflammable mixture escaping from a defective joint.

A different type of explosion was that reported recently to the Birmingham City Coroner, Dr. W. H. Davison². A man aged 63 was undergoing an operation in Queen Elizabeth's Hospital, the intention being to obliterate the cavity left after pneumonectomy. Cyclopropane anaesthesia was being used and the electric cautery needle entered the cavity, with the result

¹ *So. third Times*, Nov. 17, 1948.

² *Daily Telegraph*, Jan. 5, 1949.

that the anaesthetic exploded. Mr. R. H. F. Brain, surgeon at the hospital, said that the risks of this method were appreciated, but it was considered that they were outweighed by the advantages. Death was due to blast, and a verdict of misadventure was recorded

Universities and Colleges

UNIVERSITY OF DURHAM

The following medical degrees were conferred at a Congregation held on Dec 17, 1948:

M.B., B.S.—G. L. Anderson, Anne R. Boon, P. G. Buck, Maureen T. Cunningham, June Dickson, Irene N. Dodd, Mildred C. Gardner, Sheila L. Harrison, Elizabeth J. Hunter, A. P. M. Hurst, Eileen Hutton, Hazel E. Jephson, R. N. C. Lockey, J. McManners, J. G. Noble, Edith M. Robertson, D. Smith, J. D. R. Smith, Joan Stephens, A. E. Wright

UNIVERSITY OF LONDON

A Special University Lecture on "Surgical Aspects of Meningitis" will be given by Sir Hugh Cairns at Westminster Medical School, Horseferry Road, London, S.W., on Thursday, Feb. 10, at 5 p.m.

Professor B. G. Macgrath will give a Special University Lecture on "Malaria as a World Problem" at Westminster Medical School, Horseferry Road, London, S.W., on Thursday, Feb. 24, at 5 p.m.

The above lectures are addressed to students of the University and to others interested in the subject. Admission is free, without ticket.

UNIVERSITY COLLEGE

The following lectures will be delivered at the College (Gower Street, W.C.): Jan. 18 and 25 and Feb. 1 and 8, 5.15 p.m., Dr. E. Ashworth Underwood, "The Development of Modern Physiology, 1700-1900"; Jan. 24 and 31 and Feb. 7 and 14, 4.45 p.m., Mr. P. Johnson, Ph.D., "The Ultracentrifuge and Electrophoresis Apparatus in Protein Research"; Jan. 27, 1.15 p.m., Professor J. B. S. Haldane, F.R.S., "Some Modern Views on Evolution"; Jan. 28 and Feb. 4 and 11, 5.15 p.m., Mr. F. Bergel, Ph.D., "Some Aspects of Pharmacological Chemistry"; Feb. 2, 5 p.m., Mr. D. Abercrombie, "Speech and Society"; Feb. 15 and 22 and March 1, 8, and 15, 5.15 p.m., Dr. A. Schweitzer, "Reflexogenic Areas of the Vascular System"; Feb. 17, 1.15 p.m., Mr. G. Burniston Brown, Ph.D., "The New Philosophy of Science"; Feb. 28 and March 7, 4.45 p.m., Professor C. Rimington, "Haem Pigments in Nature". Admission to all lectures is free, without ticket.

Cedric Keith Simpson, M.D., has been appointed to the part-time University Readership in Forensic Medicine tenable at Guy's Hospital Medical School, from Oct. 1, 1948.

The title of Reader in Applied Pharmacology in the University has been conferred on Andrew Wilson, M.D., Ph.D., Ph.C., in respect of the post held by him at University College and University College Hospital Medical School.

The following candidates have been approved at the examination indicated:

M.S.—Branch I (Surgery) D. T. A. Brown, S. I. Green, H. O. Jones, D. W. Williams

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow held on Dec. 6, 1948, with Dr. W. R. Snodgrass, President, in the chair, the following were admitted Fellows of Faculty *qua* Physician: J. D. Aitchison, M.B., R. D. C. Brackenridge, M.B., J. H. Haldane, L.R.C.P.&Sed, G. Johnston, M.B., W. P. Kennedy, Ph.D., L.R.C.P.&Sed, H. R. F. Macdonald, M.B., J. Rankin, M.D.

The following were admitted Fellows of Faculty *qua* Surgeon: H. A. Benjamin, M.B., J. Cohen, M.B., W. Y. Cornock, M.B., J. M. McBride, M.B., J. D. McCardell, M.B., D. M. Macdonald, L.R.C.P.&Sed, W. Macintyre, M.B., N. McLean, M.B., R. G. MacLeod, M.B., R. G. Main, M.B., A. J. M. Mathieson, M.B., A. B. May, M.B., K. M. Mayall, M.B., I. P. Munro, M.B., T. A. Ramsay, M.B., R. P. Schach, M.B., J. M. Scott, M.B., D. M. Sinclair, M.B., R. B. Watson, M.B., T. M. Welsh, M.B., W. F. White, M.B.

The Services

The Efficiency Decoration of the Territorial Army has been conferred upon Lieutenant-Colonel W. H. Wolstenholme, O.B.E., Major (Acting Lieutenant-Colonel) A. Cowie, D.S.O., Major (Honorary Lieutenant-Colonel) G. Tudhope, and Majors E. C. Ellis and E. M. Wright, R.A.M.C., T.A.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Dec. 2

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases, a blank space denotes disease not notifiable, no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the return are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county) will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Influenza

England and Wales have been singularly free from epidemic influenza in recent years, and, apart from a few outbreaks due to virus A in residential communities at the beginning of 1947, there has been nothing to report since the mild epidemic due to virus B early in 1946. The first quarter of 1948 had the lowest figure ever recorded for deaths from influenza in the great towns. (See Table below.)

So far there has been no indication of epidemic influenza in England and Wales this year, but reports have been received of an epidemic probably due to a variant of virus B in Italy (Jan. 1, p. 39) and recently of a mild type of influenza in France and Belgium. It is not yet known what virus type, if any, is involved in France or Belgium. Since the importation of the disease into this country may be imminent it may be desirable to recapitulate briefly the main clinical features and certain measures which may be useful.

Clinical Features.—Diagnosis of an individual case of true virus influenza is usually difficult and often impossible; the occurrence of a number of similar cases at the same time is one of the most important leads to diagnosis. The onset is generally more sudden than that of a simple febrile catarrh, and the catarrhal symptoms are usually less marked at onset. Malaise and high fever with aching back and limbs are early symptoms. Headache, photophobia, and shivering are common. The clinical features vary a little in different outbreaks.

Treatment.—Penicillin and the sulphonamides are ineffective in the treatment of the primary virus infection but may be of value in the treatment of complications. Prophylactic doses of sulphonamides may be of value in an institutional outbreak where secondary infections with a sulphonamide-sensitive organism are known to be occurring.

Vaccines.—In recent epidemics in different parts of the world variants of the two main types A and B have been reported, and protective vaccines prepared against the main types have been ineffective against these variants. It is not yet known whether any existing vaccines are likely to have any value in protecting against the prevailing type, and in any case protective vaccination is impracticable as a general measure. It should be reserved for those who run special risks.

Infectious Diseases in 1948

Summation of the weekly figures for 1948 shows that the most notable feature during the year was the low incidence of influenza. The usual trend of influenza is one of a steady increase to a maximum during the first weeks of the year, but in 1948, for the first time in recent experience, no increase in mortality occurred. Whooping-cough was very prevalent, and the notifications were about 50% above the totals of recent years. The incidence of scarlet fever was also high. Notifications of acute pneumonia were slightly below the level of the preceding years. Notifications of diphtheria, which have been decreasing steadily since 1941, showed a further large fall. The incidence of cerebrospinal fever was about two-thirds that of 1947, but remains at about twice the pre-war level. Following the outbreak of 1947 the incidence of acute poliomyelitis declined considerably, but continues at about three times the pre-epidemic level in 1948. Notifications of the principal infectious diseases in England and Wales for 1948 and the four preceding years were as follows.

	No. of Notifications				
	1944	1945	1946	1947	1948
Scarlet fever	93,601	74,392	57,614	60,524	75,460
Whooping-cough	93,107	62,022	92,028	94,241	145,878
Diphtheria	29,446	25,059	18,156	10,258	7,903
Measles	117,437	443,002	154,826	399,461	396,841
Acute pneumonia	38,175	34,059	36,109	34,348	31,096
Cerebrospinal fever	2,883	2,691	2,627	3,147	1,971
Dysentery	10,150	16,333	8,441	4,179	5,534
Enteric (paratyphoid and typhoid) fevers	536	679	1,367	880	873
Acute poliomyelitis	510	799	703	8,592	2,017
Influenza. Deaths in the great towns	1,744	1,307	2,629	1,774	610

Poliomyelitis in Mauritius

Information now received from the island of Mauritius states that up to Dec. 31 a total of 192 cases have been notified with 5 deaths. Cases have occurred in ten different localities in the island, and there appears to be some spread from Port

Louis, which reported the greatest number of cases in the early stages of the epidemic. Of all the cases notified 80% have been in children aged 1-5.

Inoculation and Vaccination of Travellers

Many countries insist that travellers, before entering their territories, should produce satisfactory evidence of having been recently immunized against certain diseases—particularly smallpox and yellow fever. Inoculation against yellow fever is required of travellers who have come from or passed through an "endemic yellow fever area" when they arrive by air in a country where, although the disease does not exist, there may be conditions which permit of its development. In order to avoid detention or delays at the frontiers of countries requiring these measures travellers must provide themselves with certificates of vaccination or inoculation on the appropriate prescribed international forms.

The Ministry of Health is often asked for advice on the optimum safe time limits which should be allowed to elapse between smallpox vaccination and yellow fever inoculation. A meeting of experts was therefore convened recently to review the subject. The following is a brief summary of the conclusions reached and should be considered as the official advice to those concerned.

1. That yellow fever inoculation should precede primary vaccination against smallpox.
2. That there should be an interval of at least four days between yellow fever inoculation (when given first) and primary vaccination against smallpox (when given subsequently).
3. That if primary vaccination against smallpox is done first there should be an interval of 21 days from the date of the vaccination before the yellow fever inoculation is given.
4. That where there is evidence of previous successful vaccination against smallpox, yellow fever immunization and re-vaccination against smallpox may be carried out at the same session, but if time permits yellow fever immunization should always precede revaccination by at least four days.

Minimum Age for Inoculation

For each of the commoner immunizing procedures recommendations were also made in regard to the minimum age under which it is not desirable to vaccinate or inoculate.

Immunizing Procedure	Minimum age below which it should not be carried out
Smallpox vaccination	No lower limit. Primary preferably before 6 months (optimum 3-4 months).
Yellow fever inoculation	No lower limit. May, if necessary, be given in first week of life at full dose.
Typhoid-paratyphoid inoculation	Not under 1 year of age.
Cholera inoculation	Not under 1 year of age.
Typhus inoculation	Not under 1 year of age.

Discussion of Table

In England and Wales the notifications of infectious diseases fell sharply. There were marked decreases in the incidence of measles 841, whooping-cough 680, acute pneumonia 290, scarlet fever 272, diphtheria 24, and dysentery 24.

In contrast to the general decline in the incidence of measles large increases were recorded in Southampton 225 (due to the continuing outbreaks in Portsmouth C.B. and Southampton C.B.), Middlesex 59, and Nottinghamshire 47. A decrease in the number of notifications of whooping-cough was general throughout the country; the largest falls were in Lancashire 154 and Kent 75.

There was a decrease in the incidence of diphtheria in most areas, the only exception of note being an increase of 6 in Yorkshire West Riding. The largest fall in the notifications of scarlet fever was 44 in Lancashire.

Cases of poliomyelitis were notified in Surrey 3, London 2, Oxford 2, and Southampton 2 (Andover M.B. 2).

In Scotland there was a fall in the notifications of acute primary pneumonia 114, whooping-cough 48, scarlet fever 42, and dysentery 18.

In Eire a decrease was reported in the notifications of scarlet fever 53, measles 31, and diarrhoea and enteritis 12.

In Northern Ireland there were increases in the incidence of measles 13 and diphtheria 5 in Belfast C.B.

Week Ending January 1

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,125, whooping-cough 2,015, diphtheria 142, measles 11,121, acute pneumonia 1,050, cerebrospinal fever 28, acute poliomyelitis 20, dysentery 53, paratyphoid 3, and typhoid 7.

Medical News

Adviser on Palestine Refugees

Dr. J. D. Cottrell, medical officer of the World Health Organization, has been appointed adviser to the United Nations relief scheme for Palestine refugees.

Safety Codes

The Birmingham and District Industrial Safety Group have prepared a booklet, *Safety in the Works*, which includes three codes of safety practice for entry into tanks, vats, pits, pipes, flues, sewers, manholes, and similar confined spaces; construction and maintenance of floors, passages, stairs, and ladders in industrial premises; and for crane drivers. The booklet also reprints a note on personal protective appliances and devices by Mr. E. A. Kite, and there is also a short section by Mr. W. A. Bond on the safe guarding of milling machines. The booklet is well produced, and copies may be obtained price 1s, from the secretary of the Birmingham and District Industrial Safety Group.

World Federation for Mental Health

The articles of association of the World Federation for Mental Health, which was set up in London in August, 1948, have now been printed. The aims of the Federation include the promotion of mental health among all peoples, and of research to that end. Members of the Federation are national mental health organizations. The president is Dr. J. R. Rees, and the honorary secretary Dr. Kenneth Soddy.

Fund for Dr. J. R. Rees

Dr. J. R. Rees, President of the World Federation for Mental Health, has been voted £1,250 by the New York International Committee for Mental Hygiene for "courageous and inspiring leadership in promoting mental health and good relations among individuals, groups, and nations."

Wills

Professor John Kay Jamieson, of Trinity College, Dublin, and the University of Leeds, left £12,790. Dr. Thomas Henry Harker, chairman of the Board of Management of Southport General Infirmary, left £18,139. Dr. John Cameron, of Fortrose, left £11,298; Dr. Philip Meredith Roberts, Barton-on-Sea, Hants, £33,874; and Dr. Arthur Harold Shepard, of Dogmersfield, Basingstoke, £30,344.

COMING EVENTS

Chadwick Lectures

The following public lectures have been arranged by the Chadwick Trust (204, Abbey House, Westminster, London, S.W.1): Tuesday, Jan. 18, 2.30 p.m., at 26, Portland Place, London, W., Dr. R. F. Bridgman (Paris), "Health Services in France"; Tuesday, March 22, 4.30 p.m., at Westminster Medical School, 17, Horseferry Road, London, S.W., Dr. Helen M. M. Mackay, "A Health Service for Children"; Tuesday, June 21, 2.30 p.m., at 26, Portland Place, London, W., Dr. Sibyl Horner, "Evolution of Industrial Work for Women and Young Persons and its Effect on the National Health." Admission to the lectures is free.

Medical Films

The Scientific Film Association (34, Soho Square, London, W.1) has arranged the first of a series of monthly screenings of recent films to be given at the Medical Society of London, 11, Chandos Street, London, W., on Thursday, Jan. 20, at 6 p.m. The films to be shown on this occasion will deal with the subject of paediatrics and will include "Your Children's Sleep," "Progress Afoot," "A Case of Sturge-Weber Syndrome," "Infant Care," and "Know Your Baby." The screenings are organized primarily for the benefit of teachers of medicine.

Education for Family Life

The British Social Hygiene Council will hold a discussion on "Education for Family Life" at the Planning Centre, 28, King Street, Covent Garden, London, W.C.2, on Jan. 26, 1949, at 6.15 p.m. Mrs. Eva Hubback, Principal of Morley College, and chairman of the Education Committee of the L.C.C., will be in the chair, and Dr. Letitia Fairfield, Dr. Ethel Dukes, and Mr. Geoffrey Martin will take part. Ample time will be allowed for discussion. Information and tickets (price 1s) can be obtained at the door or from the Planning Centre.

Nursing Conference

The Royal College of Nursing will hold a conference, "Health and Sickness," from Jan. 31 to Feb. 2, 1949. Discussion will centre round ways of achieving a closer unity between preventive and curative nursing in the light of Dr. John Cohen's minority report on the recruitment and training of nurses.

Association of Whole-time Salaried Specialists

A meeting open to all whole-time salaried specialists, whether members of the Association of Whole-time Salaried Specialists or not, to discuss matters of common interest particularly in connexion with the National Health Service, will be held at the Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., on Friday, Jan. 28, at 4 p.m., with Dr. Horace Joles, President of the Association, in the chair. Tea will be served from 3.45 p.m.

Oxford Graduates Medical Club

The Oxford Graduates Medical Club dinner will be held at the Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., on Friday, Feb. 18, 1949, at 7 p.m. for 7.30 p.m. The cost is 26s., inclusive of drinks with the meal. Dinner jackets will be worn. All Oxford graduates who are medically qualified are members of the club. All who wish to attend should communicate with the honorary secretary, Mr. E. G. Tuckwell, F.R.C.S., 73, Harley Street, London, W.1.

The Association of Surgeons

The annual meeting of the Association of Surgeons of Great Britain and Ireland will be held in Dublin on May 26-28. The provisional arrangements are as follows: *Thursday, May 26*.—Business meeting. Discussion on "Surgical Ritual," opened by Sir Hugh Cairns, Sir Reginald Watson-Jones, Mr. Julian Taylor, Mr. F. Gill, Mr. D. M. Douglas. *Friday, May 27*.—Discussion on "The Use and Abuse of Streptomycin" (speakers to be announced later). *Saturday, May 28*.—Discussion on "The End Results and Treatment of Injuries to Peripheral Nerves," opened by Mr. H. J. Seddon (other speakers to be announced later). Fellows and Associate Fellows are invited to submit the titles and précis of short papers they wish to read at the annual meeting to the honorary secretary by the end of January. Those requiring accommodation in Dublin should apply as soon as possible to Hewett's Travel Agency, Hewett's Corner, D'Olier Street, Dublin. The agency is also prepared to make travel arrangements.

SOCIETIES AND LECTURES

Saturday

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—At Royal Free Hospital, Gray's Inn Road, London, W.C., Jan. 15, 3 p.m. Clinical meeting.

Monday

HUNTERIAN SOCIETY.—At the Mansion House, London, E.C., Jan. 17, 8.30 p.m. "The Founding and Influence of a School of Surgery." Hunterian Lecture by Dr. John M. Finney, junr. (Baltimore).

Tuesday

CHADWICK TRUST.—At 26, Portland Place, London, W., Jan. 18, 2.30 p.m. "Health Services in France," Chadwick Public Lecture by Dr. R. F. Bridgman (Paris).

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Jan. 18, 5 p.m. "Principles and Practice of Treatment," by Dr. R. M. B. MacKenna.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Jan. 18, 11 a.m. "Systemic Gonorrhoea," by Dr. A. H. Harkness.

ROYAL PHOTOGRAPHIC SOCIETY, 16, Prince's Gate, London, S.W.—Jan. 18, 7 p.m. "Some Observations on American Medical Photography," by Dr. Peter Hansell.

SOCIETY OF CHEMICAL INDUSTRY: FINE CHEMICALS GROUP.—At King's College (Large Anatomy Lecture Theatre), Strand, London, W.C., Jan. 18, 7 p.m. "The Approach to the Chemotherapy of Tuberculosis," discussion to be opened by Dr. James Walker, D.Sc., and Dr. P. M. D'Arcy Hart, F.R.C.P.

UNIVERSITY COLLEGE LONDON.—At Physiology Theatre, Gower Street, London, W.C., Jan. 18, 5.15 p.m. "Blood and Circulation," by Dr. E. A. Underwood.

Wednesday

HARVEIAN SOCIETY OF LONDON.—At 26, Portland Place, London, W., Jan. 19, 8.15 p.m. Annual general meeting. "A History of Surgery." Presidential Address by Mr. E. G. Muir.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330-2, Gray's Inn Road, London, W.C.—Jan. 19, 3.30 p.m. "The Larynx. Organic Nervous Affections of the Larynx, Laryngeal Paralysis. Treatment—Educational and Operative," by Mr. V. E. Negus.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Jan. 19, 11 a.m. "Treatment of Gonorrhoea and Complications," by Dr. A. H. Harkness.

Thursday

BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck Street, London, W.—Jan. 20, 8.15 p.m. Discussion: "The Problems of Dosage in Heterogeneous Media."

DURHAM UNIVERSITY: DEPARTMENT OF SURGERY.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Jan. 20, 5 p.m. "Physiology and Surgery." Fourth Rutherford Morison Lecture by Sir Henry Dale, F.R.S.

'ESTIGYN'

ETHINYL OESTRADIOL B.D.H.

*An Orally Active Derivative of
the Natural Oestrogen, Oestradiol*

Ethinyl oestradiol is unique in that it is a simple derivative of the natural ovarian hormone which is highly active when administered orally. It is now available for clinical use as 'Estigyn'.

Ethinyl oestradiol is remarkable for its high potency and dosage should be the lowest which produces the desired therapeutic effect. Manifestations of overdosage are more likely than symptoms of toxicity.

Toxic reactions, such as headache, nausea and vomiting, are rare following the administration of 'Estigyn' and are most unlikely after the usual therapeutic doses. 'Estigyn' is issued in tablets containing 0.05 mg., each tablet scored for convenience in giving doses of 0.025 mg. when the same are required. Literature and trial sample are available on request.

Vasodilatation

There is considerable evidence of the outstanding value of Cardophyllin in producing vasodilatation. The coronary vasodilatation is manifested in an increased coronary blood flow and a beneficial effect on the myocardium; the renal vasodilatation is indicated by the powerful diuresis. It also causes bronchodilatation.

A NON-OILY MULTIVITAMIN SOLUTION

This new Parke-Davis preparation represents an important advance in the administration of vitamins. In "Abidec" Drops it is now possible to give six essential vitamins, of both "water-soluble" and "fat-soluble" groups, in a stable, non-oily and non-alcoholic solution.

The ready miscibility and small dosage of "Abidec" Drops enable them to be added to infants' and children's food, either solid or liquid, without appreciably altering either taste or appearance; or the dose may be dropped directly on to the tongue with little risk of nausea.

"Abidec" Drops contain in each 10 minim adult dose:—

Vitamin A ..	5,000 Int. units	Vitamin B ₂ (Riboflavin) ..	0.4 mgm.
Vitamin D ..	1,000 Int. units	Nicotinamide ..	5 mgm.
Vitamin B ₁ (Aneurine hydrochloride) ..	1 mgm.	Vitamin C (Ascorbic acid) ..	25 mgm.

Available in 10 c.c. vials with droppers.

PARKE, DAVIS & COMPANY
HOUNSLOW, MIDDLESEX. Inc. U.S.A., Liability Ltd.

For **MULTIPLE DEFICIENCIES—** **A single supplement** **of Vitamins and Minerals**

All restricted diets call for special care to guard against limitation of essential nutrients. Cases still, unfortunately, occur where patients on roughage-free diets become depleted of vitamin C and even develop signs of scurvy.

Specific deficiencies can be avoided by the use of the appropriate preparations of single vitamins or minerals, e.g., Ascorvel for vitamin C, Betavel for vitamin B₁, iron for hypochromic anaemia and so on—or, to prevent multiple deficiencies, a single supplement of vitamins and minerals such as Complevite may be employed.

COMPLEVITE

The recommended adult daily dose provides :

vitamin A	2,000 i.u.	vitamin C	20 mg.	iodine	} not less than 10 p.p.m. each
vitamin D	300 i.u.	calc. phosph.	480 mg.	manganese	
vitamin B ₁	0.6 mg.	ferr. sulph. exsic	204 mg.	copper

Spirella

INDIVIDUAL & SURGICAL
CORSETRY SERVICE

THE Spirella System of Corsetry operates as follows. First, the Spirella Corsetiere adjusts the patented Modelling Garment (picture No. 2). Then measurements are taken over the *supported* figure, from which measurements the finished garments are individually made (picture No. 3). The finished Spirella gives control in an upward and backward direction in harmony with muscular action. Illustrations are from un-retouched photographs.

For name and address of nearest Corsetiere, see the Spirella full-page advertisement in the local Telephone Directory

WEST LONDON MEDICO-CHIRURGICAL SOCIETY—At South Kensington Hotel, 41, Queen's Gate Terrace, London, S.W.—Jan. 21, 7.15 p.m. for 7.30 p.m. Dinner meeting. 8.30 p.m. "American Medicine" by Professor John McMichael.

Saturday

BIOCHEMICAL SOCIETY—At British Postgraduate Medical School, Duane Road, Hammersmith, London, W., Jan. 22, 11 a.m. 272nd Meeting.

BRITISH ASSOCIATION OF ALLERGISTS—At University College Hospital Medical School, University Street, London, W.C., Jan. 22, 11.30 a.m. and 2.15 p.m. Annual general meeting. "Some Biochemical Investigations on the Allergens of Household Dust," by Professor C. Rimington. "Some Immunological Aspects of Desensitization with Allergens of Household Dust" by Dr. Kate Maunsell.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Benson.—On Dec. 30, 1948, to Eileen (nee Arthur) wife of Ronald Benson F.R.C.S. a daughter.

Powell.—On Jan. 3, 1949, at Milland Vicarage, Liphook, Hants, to Leonore (nee Trench) and Denis Powell M.A. M.B. Ch.B. a second daughter.

Prentice.—On Dec. 17, 1948, at Colchester, the wife of Ian Prentice M.C. M.B. twins, a son and daughter.

MARRIAGES

Crowell—Gunderson.—On Dec. 24, 1948, in London Patrick L. Crowell to Eileen M. Gunderson.

McGhee—Copeland.—On Dec. 4, 1948, at Caxton Hall Westminster, London S.W., David McGhee, M.B., Ch.B., Ph.C., to Victoria Eugénie Copeland, of Bollington, Cheshire.

Pordie—Roberts.—On Dec. 18, 1948, in London, Anthony W. Purdie, M.B., Ch.B., F.R.F.P.S. M.R.C.O.G., to Erica M. G. H. Roberts B.Sc., M.B., Ch.B., D Obst. R.C.O.G.

DEATHS

Addison.—On Jan. 5, 1949, at St Mary's, Isles of Scilly, William Bruce Addison, M.B., Ch.B., aged 85.

Alexander.—On Jan. 4, 1949, at Killearn Hospital, John Cassels Alexander, M.B., Ch.B., formerly missionary at Idu, Calabar, Nigeria.

Bullen.—On Dec. 31, 1948, at Yelkerton John Welply Bullen, M.D., Colonel A.M.S., retired, aged 85.

Falkner.—On Jan. 7, 1949, at a Bournemouth nursing home, after a short illness Berkeley Foote Falkner, L.R.C.P.S.I. and L.M., much loved husband of Annie Elizabeth, late of Woodleigh Vivian Park Swanage, aged 81.

Gibson.—On Jan. 5, 1949, as the result of an air crash, Anne Gibson, M.D. Ed Pastmore.—On Dec. 31, 1948, William Henry Pastmore, M.R.C.S., L.R.C.P., of Mornacott, Carshalton, Surrey, aged 76.

Phillips.—On Dec. 25, 1948, at Balch Glas, Nevin North Wales George Phillips, M.D. Ed., aged 79.

Pullin.—On Dec. 25, 1948, at Rahere, Honiton Devon Bingley Gibbs Pullin, M.R.C.S.

Raw.—On Dec. 26, 1948, at Alnmouth Northumberland, Stanley Raw, M.D., F.R.C.S. Ed., aged 70.

Serman.—On Dec. 23, 1948, William Serman, M.D., of the Department of Pathology, Manchester University, aged 53.

Wilson.—On Dec. 28, 1948, at Riverside, 9 Trowlock Avenue, Teddington, Middlesex, Graham Lionel John Wilson, M.R.C.S., L.R.C.P., aged 84.

Young.—On Dec. 28, 1948, at Bedford, William John Young, M.R.C.S., L.R.C.P., of Bath House, Harston, Cambridge, aged 79.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

"Rapid" Rat Test for Pregnancy

Q.—A request for the Aschheim-Zondek reaction of a patient complaining of 7½ weeks' amenorrhoea, and whose physical signs were compatible with early pregnancy, has been answered by this report: "Rat test weakly positive." What is the breed of rat used, how is the test carried out, and what is the percentage reliability?

A.—Many biological tests for pregnancy in which the rat is used as a test object are available, but that most likely to have given rise to this question is one introduced in recent years, often called the "rapid" rat test. Here again several techniques are described. Tame female albino rats 21 to 30 days old are injected either subcutaneously or intraperitoneally with 1 ml. of a first morning specimen of the urine under test. The animal is killed two hours later and the ovaries are immediately exposed and examined. If they are pale or pale pink the reaction is negative, but if one or both are light to dark red it is positive. In other words, the criterion is the degree of vascularity of the ovaries, and it will be appreciated that the accuracy of the test depends a good deal on the experience of the observer. It is stated that it is more reliable if two or three rats are used for each test, but with only one rat many workers still claim 95% accuracy. Further details of this type of test are given by U. J. Salmon and others (*J. clin. Endocrinol.*, 1942, 2, 167), H. S. Kupperman and R. B. Greenblatt (*Sth. med. J.*, Nashville, 1946, 39, 158), and P. H. Fried (*Amer. J. Obstet. Gynec.*, 1947, 54, 689).

Testosterone for Prostatic Enlargement

Q.—(a) Is there reasonable evidence that benign enlargement of the prostate is reduced by administration of testosterone propionate? (b) Has prolonged administration of this drug any harmful effect? (c) If so, what is the safe maximum dose and over what period should it be given?

A.—Testosterone was originally suggested as a method of treatment for benign enlargement of the prostate, on the ground that such enlargement occurs in later life when the testicular secretion of testosterone is beginning to fail. There have been many clinical reports of symptomatic improvement. However, a subcommittee of the Medical Research Council was unable to produce convincing evidence—at least in so far as objective data were concerned—that testosterone had such a beneficial effect. There is no evidence of any harmful effects of this substance given in therapeutic dosage over a long period in adults.

Pressure-cooker as Sterilizer

Q.—Can a pressure-cooker be used for sterilizing small dressings? The working pressure is given as 15 lb. What would the method be?

A.—The answer to both parts of this question depends on the design of the cooker. A pressure of 15 lb. (6.8 kg.) of steam will not ensure absolute sterility—although, of course, it will in any case destroy all pyogenic cocci and other non-sporogenous bacteria—if the steam is mixed with the whole of the air contained in the cooker when it is closed. For efficient operation there should therefore be a tap through which the contained air can be expelled by steam before the pressure is allowed to rise; alternatively, the cooker could be closed when the water is already boiling in it, but this might be difficult and liable to produce scalded fingers. Dressings so treated would be damp. Presumably it is not suggested that this proceeding should be resorted to except in an emergency. Apart from being possibly unsatisfactory for the reasons given, it is a waste of time when sterile dressings can so easily be obtained commercially.

Russell Viper Venom

Q.—What is the explanation of the fact that, while the venom of the Russell viper is used as a source of thromboplastin in the estimation of prothrombin and as a haemostatic in haemophilia, when it is injected by the snake itself it causes intense haemorrhage with constant oozing of blood from the punctures?

A.—It is true that Russell viper venom is an extremely powerful blood coagulant, but this action is most pronounced when the venom is diluted 1 in 1,000 or even 1 in 10,000. At higher concentrations there is an anticoagulant effect which outweighs the clotting activity, and, moreover, the undiluted venom may quite rapidly dissolve any clots which form. The haemorrhage from the site of injection of venom by the snake is therefore probably due to this local proteolytic and anticoagulant effect where the venom is highly concentrated, and to the necrosis which results from capillary thrombosis and damage to tissue cells produced by the venom as it spreads through the tissues.

Vegetable Fats and Gall-stone Formation

Q.—Is it safe to give fats of purely vegetable origin to persons with a gall-stone diathesis? Is phytosterol liable to form gall-stones if taken in any quantity?

A.—It is generally believed that vegetable sterols are not absorbed by mammals, although this is disputed. However, the amount of cholesterol excreted in the bile is not related either to the concentration in the blood or to the amounts in the diet. There is therefore no reason to suppose that the amounts of vegetable sterols in the diet have any influence on the formation of gall-stones.

Respiration at Birth

Q.—Can you explain the mechanism by which a newborn infant's respiratory centre is stimulated to initiate breathing during normal labour?

A.—From the end of the first trimester of pregnancy the foetus in utero can, and in certain circumstances does, exhibit movements of the chest wall and diaphragm similar to those of respiration. Post-natal respiration can therefore, to some extent, be considered a continuation of an intrauterine function which has appeared along with the development of the nervous and muscular systems. Several factors seem to play a part in the onset of breathing after birth, but probably the most significant are the oxygen and carbon-dioxide levels in the blood. It is still unknown whether an increase in the latter or a decrease in the former is the more important, or whether both act together in a cumulative way. There is, however, an optimum concentration of these gases, and too little or too much of either hinders the onset of respiration. The physiological degree of asphyxia present at birth is a continuation of an intrauterine state, increased by the effect of uterine contractions on the placenta during labour, and ultimately brought to a head by the spontaneous cessation of the circulation in the placenta and cord or by ligation of the cord. Incidentally the natural birth process may also favour post-natal respiration in that compression of the chest wall, which is inevitable in the second stage, tends to squeeze out any liquor amnii from the trachea and bronchi.

In addition to the chemical stimulus to the central nervous system other factors undoubtedly play an important part in the onset of respiration, and among these are the numerous external stimuli to which the child is suddenly exposed. These include not only the sensation of cold and touch applied to the skin, but probably muscle and joint sensations. The face, particularly the area around the mouth and nose, is thought to be especially susceptible to external stimuli. It has also been suggested that a rise in blood pressure associated with cutting off the placental circulation may reflexly initiate respiration by stimulating the aortic and carotid sinus mechanisms. This, however, has been shown not to be an essential factor. It is possible that the different types of respiration seen at birth—for example, "the gasp" as opposed to a quiet rhythm—are the result of different mechanisms, the gasp implying some derangement of the higher nerve centres, often due to asphyxia. The whole problem is complicated, and for further

details reference should be made to *Researches in Pre-natal Life*, by Sir Joseph Barcroft (Blackwell Scientific Publications, 1946). Attention was drawn recently to the importance of Sir Joseph Barcroft's work in this connexion by Dr. W. N. Leak (*Journal*, Oct. 30, 1948, p. 797).

Neglected Cleft Palate

Q.—A woman aged 30 has a large congenital cleft of the palate involving only the soft palate and uvula and affecting her speech. She is very nervous, and it is thought that her defect contributes largely to this state. (a) Would an operative repair followed by speech training improve speech at this stage? (b) Is it possible to construct a prosthesis to fill a defect so far back in the mouth, and would this, again followed by training, improve speech?

A.—In a neglected cleft of this kind the value of operation depends on several circumstances, local and general; these include the width of the cleft at its posterior end (at the uvula), and the distance of this point from the posterior pharyngeal wall; in general, operation is more justified for the intelligent patient, who will co-operate fully in later speech therapy. If the patient fears an operation, this will weigh against advising it. A prosthesis can always be constructed, but its efficiency depends on local conditions. It will never give normal speech, but with careful training it will usually confer some improvement.

Retinitis Pigmentosa

Q.—What vitamins should be pushed in the treatment of retinitis pigmentosa? Please recommend a suitable dosage for a primigravida of 26 with this condition.

A.—None. There is no rational basis for the use of any of the vitamins in retinitis pigmentosa. Some years ago the intramuscular injection of vitamin A was much publicized, but without justification.

Galvanism in Hemiplegia

Q.—What is the value of the treatment of hemiplegia by a galvanic current passing between an anode on the parietal region and a cathode over the side of the neck? It is claimed that this stimulates the cervical sympathetic ganglia and improves the cerebral circulation, resulting in restoration of function. I shall be grateful for your opinion and references to literature.

A.—There is no scientific basis for such a form of treatment. Krusen (*Physical Medicine*, Saunders, Philadelphia, 1944) states: "It was claimed that the current from the negative pole produces a 'stimulating' effect on the tissues beneath the electrode. Recent reports indicate that this is untrue." Similarly Kovacs (*Light and Electrotherapy*, Kimpton, London, 1945) points out that there is no good evidence that the cathode has any more stimulating effect than the anode. If the cervical ganglia were stimulated by this means it is open to question whether the effect would be beneficial. Vasoconstriction would result and the cerebral circulation might be further impaired.

NOTES AND COMMENTS

Invalid Tricycle Association.—This is a non-profit-making organization which was founded in January, 1948, to help disabled people who use invalid carriages. It puts members in touch with each other, advises them on touring in this country and abroad, helps them with any problems of maintaining and insuring invalid tricycles, and runs a quarterly magazine called the *Magic Carpet*. Information may be obtained from the honorary secretary, Mr. Robert Lee, 18, Kings Drive, Edgware, Middlesex.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Attology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1. OFFICE: 9 a.m. to 5 p.m. TELEPHONE: EUSTON 2111. SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JANUARY 15 1949

THE SECRETARY REPORTS

A LARGER MILEAGE FUND

The Ministry has responded to the General Medical Services Committee's urgent representations on behalf of rural practitioners made at a meeting on Dec. 22, 1948. The Mileage Fund, now standing at £1,300,000 per annum, has been raised to £2,000,000 per annum, an increase of rather more than 50%, the increased fund to operate as from July 5, 1948. Of the £700,000 increase £200,000 comes from the Special Inducement Fund and £500,000 is new money provided for the purpose. The new mileage fund of £2,000,000 will cover rural mileage generally and mileage for rural practitioners undertaking maternity under the official scheme.

Betterment

It had been intended to await the establishment of the Whitley machinery before pressing the profession's claim for a betterment factor bearing some relation to the fact of changed money values. But, in view of the delays in establishing Whitley machinery through the difficulties raised by local authorities in their particular field, it has been decided to press for an improved betterment factor forthwith. The newly created Joint Committee of Consultants and Specialists will co-operate with the General Medical Services Committee in presenting a case to the Ministry.

An expert's up-to-date report has been obtained which shows that, if 100 is taken as the professional classes' cost-of-living figure in 1938, the appropriate figure for to-day is 185. A summary of this report will be published in these columns next week. When the Ministry laid down the figure of 20 for betterment, the professional cost-of-living figure, in relation to 100, was 150. The margin between 150 and 185 represents the increased cost-of-living for the professional classes between 1946 and 1948. These figures speak for themselves. The Ministry has been asked to receive a joint deputation from the two Committees on the subject.

Graduated Capitation Fee

It was suggested in a recent letter that the only satisfactory way to deal with the insufficiency of remuneration of those with smaller lists would be by a system involving a graduated capitation fee, with a higher capitation fee for, say, the first 1,000 patients, and a falling capitation fee as the number rises. It may be useful to examine the pros and cons of this kind of proposal, taking as an example the figure of 1,000, though the figure might be larger or smaller.

The idea can be examined quite apart from the size of the capitation fee or, better still, on the assumption that a satisfactory capitation for the maximum list is paid. The higher capitation fee for the first 1,000 would be balanced by a lower capitation fee for the last 1,000, the average for the maximum list being the agreed average capitation fee. It seems likely—the investigations now proceeding will confirm or refute it—that a substantial part of the hardship now being experienced is falling on those with smaller lists. It may well prove that it is at this end of the scale that Spens is least applied. It is certainly true that in rural areas generally the lists are too small to secure an adequate remuneration—a position which will be ameliorated to some extent by the increase in the mileage fund.

Is the tapering system open to objection on principle? When it first appeared in the Willink White Paper we criticized it on the ground that it was an illustration of a commercial practice

of a penny each or three for tuppence. One of the criticisms of the universal basic salary proposal was that it led to a tapering capitation fee position. Nevertheless, it has been suggested that it may be useful while we are awaiting the results of the Spens inquiries to examine such a proposal without prejudice.

What are the reasons for smaller lists? They may be due, as in rural areas, to relative sparsity of population. They may be due to a higher-than-average ratio of doctors to population, this, in turn, being due to other causes. In the case of an individual practitioner not in such an area the smaller list may be due to his own decision, to the thoroughness or slowness with which he prefers to work, or to simple failure to attract patients to himself. The proposal to make higher than average the rate of remuneration for, say, the first 1,000 or 2,000 patients, with a corresponding reduction for additional patients, would presumably be generally applied. This would mean that practitioners in all the groups just described would benefit. Would that be fair? Wherever, by the circumstances of the area, it is impossible for practitioners to have higher than average lists, the result would certainly be fair. Whether it would be equally fair in the case of the practitioner who just does not attract patients to himself, or who deliberately restricts his list, is open to discussion, though it might be argued that the over all result would be no less satisfactory than the uniform capitation fee system.

Such a tapering arrangement might, one supposes, encourage voluntary limitation of lists. It would raise the average rate of payment per patient for the smaller lists without interfering with the existence of or the remuneration for larger lists. It would meet the point that the ratio of expenses to receipts is likely to be higher in the smaller practice than in the larger one. It would probably make it possible to abolish basic salary and the inducement fund—except in exceptional cases such as the Highlands and Isles. The Mileage Fund arrangements—with a large fund—would continue in operation. It would probably be preferred to the universal basic salary as a way of securing the application of Spens to practitioners with smaller lists. Though it may be difficult to justify on grounds of principle a method to which the Association has in the past been opposed—namely, the application to medical remuneration of the idea of reduction for quantity—what can be agreed is that, like other ways of solving our current problems, it is a method which should be considered.

Theoretically another possibility is an increased capitation fee for the second thousand on the list or for the thousand between 1,500 and 2,500.

Perhaps correspondents to these columns would discuss this and other ways of solving this particular aspect of the remuneration problem.

Voluntary Levy

Should the expenses of local medical committees be paid from national funds or from local medical pools? This was a question which came before the last Conference of Local Medical Committees. At first sight it might appear that a good case exists for asking the State to pay. But the State does not pay without exercising control in proportion to what it pays, and it would no doubt want to supervise the payments made and possibly the staff appointments also. The Conference came down strongly in favour of a continuance of the system of Insurance Acts under which the expenses of local medical committees are met by the practitioners themselves. Only in this way can the freedom of local medical committees to conduct their own affairs in their own way be retained.

The sum of money is in ordinary cases relatively small, but a special problem does exist in such sparsely populated areas as Northern Scotland, where the cost incurred by local medical committees for the travelling and subsistence expenses of its members in attending meetings is proportionately very high. Rather than depart from the principle, the Conference asked the General Medical Services Committee to look into this as a special problem and to find a solution.

National Health Service

SPECIALISTS' FINAL CONTRACTS

The Joint Committee of Consultants and Specialists discussed with the Ministry of Health on Jan. 7 the Ministry's proposals for the final contracts for consultants and specialists under the National Health Service. Further discussions will take place.

SCOTTISH ASSISTANTS TRAINING SCHEME NO MINIMUM LIMIT

The arrangements made for the Training of Assistants Scheme under the Scottish Act differs in certain respects from the English Scheme described in the *Supplement* of Oct. 30, 1948 (p. 149). The Department of Health for Scotland has agreed, in consultation with the General Practice Subcommittee of the Scottish Negotiating Committee, that to limit the application of this scheme to practices of 2,000 and over would, in Scotland at any rate, very probably preclude from participation in the scheme a number of rural practitioners who would be eminently suitable as trainers of young general practitioners. Each application will therefore be considered on its merits regardless of the number on the list of the applicant.

Selection will not be as in England by local medical committees, but on a regional basis by a committee representative of the local medical committees in the region, as well as consultants probably selected from a panel to be nominated by the regional consultants and specialists (including hospitals) committees, and one representative of the university of the region.

TRAINEE ASSISTANT SCHEME

Local medical committees are having difficulty in considering claims put forward by practitioners for the employment of trainee assistants. A number of points require clarification, and discussions have taken place with the Ministry in the hope that a further circular can be issued setting out some general lines on which applications should be judged.

CONFIDENTIAL TREATMENT OF V.D.

The Minister of Health has made regulations to maintain the principle that information about people attending venereal disease treatment centres shall be treated as confidential (S.I. 1948, No. 2517). This principle was originally contained in the Public Health (Venereal Diseases) Regulations, 1916, which were revoked by the National Health Service Act. The Ministry states that the reasons for singling out venereal diseases in particular for statutory regulations are essentially psychological, for the real safeguard lies in the normal confidential relationship between doctor and patient. The records of all patients, whatever they may be suffering from, should be treated as strictly confidential in the sense that the condition of individual patients should not be disclosed without their consent.

PRIORITY MILK FOR SICK CHILDREN

On the recommendation of his medical advisers, the Minister of Food has arranged for the medical certificates recommending priority allowances of milk for sick children temporarily absent from school to be valid for a period of four weeks instead of one week as at present.

NO MORE FLAG DAYS HOSPITAL APPEALS FORBIDDEN

The Minister of Health has announced that since hospitals in the N.H.S. are no longer dependent on voluntary financial help for normal needs he regards it as improper for them to appeal for funds. There is no objection to their accepting gifts of money from independent bodies or people, but the following practices should cease: Advertisements in the Press or elsewhere (existing posters should be removed). Requests to indi-

vidual subscribers by letter or otherwise. Placing of collection boxes in railway stations, public houses, etc. Requests to patients for donations; contributory schemes conducted by the hospitals themselves. Radio appeals, flag days, bazaars, fêtes, etc. Employment of hospital staff in collecting voluntary funds (there can be no objection to staff giving their own time to outside voluntary efforts, such as Alexandra Rose Day, but the use of uniformed nurses for this purpose should cease).

WINCHESTER MEMORANDUM

At a recent meeting of the Organization Committee representatives of the Winchester Division who had come up to London at the invitation of the Committee explained the proposals contained in their Memorandum. (The Winchester Division has since issued a revised Memorandum.)

The Winchester Memorandum has been circulated to all Divisions and Branches and has aroused much interest. It criticizes the present constitution of the central Council and calls for the election of a larger proportion of members by direct vote, the aim being to secure a closer link between members of Council and constituencies they represent. The Memorandum also expresses the view that new methods should be found to cope with the burden of work at Representative Meetings and makes certain suggestions for dealing with this and other problems. That there is widespread agreement with the aims of the Memorandum, though not necessarily of the methods proposed, was shown by a carefully prepared and detailed analysis of the comments and views of other Divisions drawn up by the secretary of the Winchester Division.

The Organization Committee has also considered resolutions and suggestions from other sources, and in the near future will submit to the Council suggestions for dealing with the problems raised. In due course the Council's own proposals will be published, and opportunity will thus arise for full discussion both in the Divisions and by the Representative Body.

HEARD AT HEADQUARTERS

Wide Spectacles

A correspondent complained in these columns last week (p. 17) that spectacles for eyes whose pupil distance exceeds 70 mm. are not obtainable through the N.H.S. This is incorrect, though the procedure by which they are obtained is rather tortuous. After the patient has got the appropriate form from his G.P. and had his eyes examined he presents the prescription to a dispensing optician. If the pupil distance is 68 mm. or less, well and good; if it is greater, N.H.S. spectacles can be obtained only through the hospital service. However, we are told that some opticians are sparing the tempers of these unfortunate people by accepting prescriptions for spectacles for wide-set eyes and meeting the extra cost themselves from the ordinary dispensing fees.

The Association's Founder

It is just a hundred years ago—in 1849—that the founder of the Association, Charles Hastings, became its President. He had been Chairman of Council ever since the Association was formed 17 years earlier and was to remain Chairman for 16 years more, but he was President for only one year, 1849–50, when the Association returned for its annual meeting to its native Worcester. It was in the year of his presidency that he was knighted. There have been six other instances of the Chairman of Council becoming President, though only one of them in this century—Mr. Souttar being elected Chairman of Council in 1939 and subsequently becoming President. There have been two instances in the history of the Association of a man holding all three offices, of President, Chairman of Council, and Treasurer.

The School Medical Service

It was interesting to hear the head mistress of the Accrington High School for Girls state at a health education symposium arranged recently by the Ling Physical Education Association that the "Charter for Health" prepared by the British Medical Association was being used in her school as a 'textbook' for health teaching. A great deal of care was given to the Charter, and it might well form a framework for instruction in health. One of the addresses in the symposium was given by Dr J L Dunlop, M O H., Hertfordshire, who discussed very frankly the limitations of the school medical service. He felt that now that a comprehensive medical service was available for everybody the school medical service was likely to become more and more just a means of detecting children with defects, and not very effective at that. He would feel happier if he knew that in each school there was a teacher, or more than one teacher, charged with the definite responsibility of observing the performance of the children from the health point of view, so that the doctor coming to the school once a year or every six months could have the children who needed particular attention brought to his notice.

The Future of Nursing

The Association's Committee on Nursing, whose last report to the Council was highly praised, is continuing some useful work behind the scenes. The proposals for nursing legislation which it is considering and revising in the light of consultations are confidential. The Committee is also considering the economics of the employment of skilled nurses and the use of hospital facilities, and studying the economical use of nurses in industry. These nurses are said to number about 4,000—many more than before the war, but not so many as during the war years—and it is estimated that during the next five years at least another 5,000 nurses may be needed in this developing field. The use of trained nurses in radiology, in public health, and in mental health is also on the Committee's agenda.

Questions Answered

We publish here the answers to a selection of questions that seem to be of general interest.

Engaging an Assistant

Q.—I am taking a new assistant. Should I notify the executive council of his acceptance or should I leave it alone?

A.—The terms of service require that a practitioner shall not, except for a period of less than three months employ an assistant to attend his patients without the consent of the executive council. The terms of service also require that the name of any assistant should be notified by the practitioner to the executive council. The responsibility for approving the employment of assistants rests on the shoulders of the local executive council. The approval of the Medical Practices Committee is not required to the employment of an assistant unless it is proposed to place the assistant's name on the medical list.

Disposal of Superannuation Contributions

Q.—Is the balance of the 6% contributions for the superannuation scheme plus 8% contributions by the State paid to the doctor's estate if he dies shortly after receiving his pension and his wife dies a year or two after him or predeceases him?

A.—No. But in every case the doctor or his estate will receive in one form or another at least the equivalent of his own contributions to the superannuation scheme. For example, a doctor who is entitled to no benefit or transfer value under the scheme receives back his own contributions with compound interest at 2½%. A doctor who is not entitled to a pension but who is entitled to a retiring allowance the amount of which is less than the amount of his contributions plus compound interest will have his retiring allowance increased by the amount of the deficiency. In the case of a doctor who dies shortly after receiving his pension and retiring allowance, his legal personal representatives would become entitled to a death gratuity, and his widow would receive a widow's pension under the scheme.

If, while receiving the widow's pension, his wife dies or remarries and the aggregate amount of the payments to her, to her husband, or to her husband's legal personal representatives by way of pension, retiring allowance, or death gratuity is less than the amount of his own contributions with compound interest, the widow or her legal personal representatives would receive a sum equal to the deficiency.

Correspondence

Implementation of Spens

SIR.—General practitioners will welcome the Secretary's report in the *Supplement* of Dec 25 (p 235). The report clarifies to a great extent the position with regard to the application of the Inter-Departmental Committee's findings. At the recent Conference of Local Medical Committees I asked if actuarial figures were available to show how the total sum available for general practitioner services measured up to the Spens recommendations. The Secretary's report shows that we are receiving only the shadow for the substance. The total sum available for general practitioner services falls far short of the Spens recommendations.

The Spens Report states that, "having regard to the conditions of general practice, not only in the age groups above 40-49 but between 35 and 40 and even between 30 and 35 doctors ought to receive substantially the same remuneration as between 40 and 49 for the same burden of practice." It must be quite apparent from the Secretary's report, even applying only the 55% and the disputed 20%, to the 1939 figure that the total sum for general practitioner remuneration must be very substantially increased. The 20% betterment figure which the Government proposes does not "have direct regard not only to estimates of change in the value of money but to increases which have taken place in incomes in other professions."

If we accept the Government figure as a temporary basis of remuneration, 75% of general practitioners between 30 and above to the age group 40-49 for the same burden of work should receive over £2,010, 50% should receive over £2,613, 25% over £3,216, slightly less than 10% over £4,020, and a small proportion at least £5,025. The Secretary states "that a betterment factor of one third applied to the gross income and of one-fifth to the net income in no way represents the change in money value which has taken place." Most of us will heartily agree with this statement.

The total remuneration provided for general practitioners under the N.H.S. Act is approximately £45 million. Can anyone seriously claim that the latter figure interprets the Spens recommendations? If we take the Minister's figure of population at 47,750,000 and take 95% of this, we get 45,362,500. At 18s per head this would produce a central fund of £40,826,250 and after deducting £1,000,000 for mileage we are left with £39,826,250. On the assumption that 20,000 principals are taking part, the average payment is £1,991 6s 3d gross, if assistants are included this sum should be reduced accordingly. This gives a net figure in the region of £1,327 10s 10d per doctor spread over the whole general practitioner service.

The Minister has frequently publicly asserted that practically the whole population is availing itself of the public service. In Glasgow it is claimed that at Sept-30, 1948, only 14,381 out of a population of 1,093,580 were not on a doctor's list. Even with a 4,000 list the Spens figure cannot be reached, and most practitioners will agree that this number is much too large for proper treatment. Unless there is an immediate all-round increase in remuneration, based on a reasonable number of patients not only the Service but the doctors will break down. Rural and suburban areas must have special consideration where relatively more time is required for visits. There is ground for suspecting that the capitation fee has been based more on the inadequate N.H.I. rate than on the Spens Report.

The committee recommended a net capitation fee of 15s 6d in terms of 1939 values, or 15s after deductions for mileage, inducements, etc. This represents over 22s 6d on 1939 values and even if the Government betterment figure of 20% is applied the total is 27s. On the basis of 45 million making use of the Service the total sum available for distribution should be

\$60,750,000, with a further £2,062,500 for, *inter alia*, mileage grants and special payments. Pandora's box has been opened and we are left with hope and charity. The humiliating basic salary should either be applied *ipso jure* or abolished.—I am, etc.,

A. SMITH POOL.

Car Allowances for Whole-time Specialists

SIR,—We strongly endorse the views expressed by the Leicester group of whole-time specialists (*Supplement*, Dec. 18, 1948, p. 229). We too are whole-time specialists responsible for the treatment of approximately 50,000 accidents a year, with a high incidence of serious accidents referred to us by other hospitals.

Our old board of management, in founding this new type of hospital for accidents in 1941, aimed at establishing an immediate specialist service on a 24-hour a day basis for all serious accidents. This board asked us to establish our homes as close to the hospital as possible, and to provide an efficient telephone service and quick transport facilities to the hospital. The last requirement meant the purchase and maintenance of a car, for public transport cannot adequately cover our emergency calls. The board recognized this, and a car allowance towards these expenses was given. The years of our experience confirm the correctness of this decision.

Since July 5 we are informed that no car allowance other than 6d. a mile for "emergency visits" will be allowed to us. This concession, in our experience, is entirely inadequate. For example, on our 24-hour duty day we are responsible for all admissions. On that day we prefer to stay in the hospital until a late hour. Only then have accident admissions ceased and is it reasonably safe to go home; by then, too, public transport has also ceased and our cars are essential to take us on this journey. In order to qualify for "emergency visits" are we to quit the hospital, say, at six o'clock, knowing well that we will have to answer several emergency calls?—a state of affairs which would sadly and unnecessarily affect our efficiency and indeed the very spirit of our service to our patients. Yet under present regulations we have no other alternative, for without an adequate car allowance we cannot afford to maintain our cars. Since July 5 we have continued to provide our emergency service in the old manner but at our own expense, believing that authority has not yet had time to examine the problem in detail.

We are rather amused that our hospital is euphemistically considered to be "our office," that regulations then proceed to consider transport problems to "our office" on equal terms with those to any other office. Anything less like the accepted meaning of an office than a modern large accident hospital, with its urgent demands at all hours to its staff, is difficult to imagine. The term ceased to be amusing when we sought a measure of relief from our car expenses under Schedule E. The income tax inspector, when asked how we were to fulfil our duties to our patients at times when public transport was not available, replied, to use his own words, that "he couldn't care less." We were not on duty, in his official view, until we actually reached "our office," and how we got there was not his affair.

We feel, therefore, that these matters should be brought to the notice of the Ministry and that any contract we may be asked to sign shall contain recognition that in such an emergency service a car is essential to our work. This can be done either in the form of an adequate annual allowance or by a clause recognizing the necessity of a car in order that an income tax rebate under Schedule E may be obtained.—We are, etc.,

Remuneration

SIR,—I wish to congratulate Dr. A. W. McHaffie on his letter published in the *Supplement* of Dec. 4 (p. 209). I do not, however, wish to congratulate the officials of the Scottish office of the B.M.A. on the statement made to the Press and published in the *Glasgow Bulletin* on Saturday, Dec. 4. The state-

ment so far as I could make out implied that the Scottish Secretary thought that the doctors were merely grumbling because the quarterly cheques did not come up to standard. It was clearly stated by the Scottish Secretary that the doctors were multiplying the amount received by four and saying, "Is that all we are going to get?" Well, may I ask what does the Scottish Secretary think we should do—multiply by 8 and subtract the number we first thought of and then divide by 2 and hope for the best? This is the help we are getting from the officials of the Scottish office of the B.M.A.

I thought we were fighting for an all-round increase in remuneration, and the kind of statement published in the Press is only likely to convey to the public the idea that we are grumbling about nothing. The officials suggested that "the interim payments [made to account] would adjust themselves by the end of the financial year." So things have just to be left alone and they will adjust themselves. Isn't that good helpful advice coming from B.M.A. officials in Edinburgh? Just sit back and the capitation fee of 15s. 2d. will adjust itself by the end of the financial year; the inadequate mileage will automatically adjust itself, and the basic salary will be sent to all who require it—just like that. I fear that the B.M.A. officials in Edinburgh could not possibly have read the last paragraph, column 2, p. 204, *Supplement*, Dec. 4, 1948.—I am, etc.,

Callender, Perthshire.

F. C. M. McILWRICK.

* The Scottish Secretary writes: The statement to which Dr. McIlwrick objects referred only to the September payment, which was for a number of reasons much below a normal quarterly payment. Endeavour was made to explain some of the misapprehensions to which this incompleteness had given rise. No reference was made to the inadequacy of the capitation fee. As was explained in a personal letter to Dr. McIlwrick on Nov. 8, the Association is already taking active steps towards overcoming the difficulties experienced by many rural practitioners since the inauguration of the new Service. These steps are aimed at securing a satisfactory increase both of the capitation fee and mileage payments.

Appealing for Basic Salary

SIR,—I have made my appeal for the basic salary and in doing so have given the local medical committee sundry painful reasons for my request. The following letter from the executive council arrived in due course:

"I beg to inform you that my Council after consultation with the Local Medical Committee have decided not to consent to payment to you of the fixed annual amount of £300.

"If you wish to appeal you have a right to do so to the Minister of Health."

That is all, absolutely all. No reasons given, just the above autocratic curt refusal—not even the season's greetings—so brutal it might well have emanated from the Kremlin. Besides which, in order to make my appeal to the Minister more than just a gesture, I need the reasons for refusal. Surely I am entitled to know why my request has been turned down, or is this expecting too much from the executive council? Perhaps I am being fussy and am merely unfortunate in my correspondents, but the council's letter to my mind somehow carried a sting. Perhaps it was the lack of punctuation.—I am, etc.,

Thame, Oxon.

E. GRANGER.

Evening Surgeries

SIR,—I would like to hear the opinions of your readers on the cessation of evening surgeries. To my mind these are totally unnecessary. I would rather do three hours of consultations in the morning, leaving the rest of the day for visits without rushing back to a hurried meal and start again. I would get more time for leisure and study and feel fitter for another day's work. My surgeries are sadly depleted when a good film appears at a local cinema or a prize fight is being broadcast.

I contend that these evenings are a waste of time. Patients for whom I prescribe medicines never see them until the following evening, when they come home from work. Most of them look tired and hungry and would be better off at home than sitting in a waiting-room. I never see children at night. Most patients require certificates only, which could easily be picked up, say, on Saturday mornings. After holding a census of my evening surgeries I find they are made up of women with

domestic troubles—where I do not wish to interfere—young boys and girls for tonics—who should go to a youth club—and one or two boils or abscesses—where the owners are unfit for work and could see me in the mornings.

Abolishing evening surgeries would ease practice expenses both for the hard-pressed rural doctor and me. It would please the wife and the Ministers of Fuel and Power and Transport. I feel that this is a question which should be seriously considered.—I am, etc.,

London, N.13.

VICTOR M. SEIFERT.

Better Capitation Fee

SIR.—The doctors who are now so desperately anxious to limit the number of patients to 2,500 or less should remember that no one has more patients than he had before July 5; the only difference is that they are now State patients. The inference, therefore, is that these doctors are unwilling to give the patients the extra attention which they now demand.

Whereas I heartily agree that 18s. per head is inadequate, it is dangerous to say with one voice we are not paid enough and with another to claim that the successful man, whether his success is due to his bedside manner or to his ability, should be paid less per head than at present, for that is what the scaling down of the capitation fees over a certain maximum number of patients amounts to. I would point out that the upper limit was agreed to by the profession, knowing full well what a vast amount of extra work would follow the introduction of the Health Service. To sum up, let us fight for the better capitation fee, so that a man with 2,000 patients can live comfortably, but let there be no brake on incentive and ability.—I am, etc.,

Newport Pagnell, Bucks.

A. A. CLAY.

A Call to Action

SIR.—By a *volte face* and a snap plebiscite at a time when the profession was in a strong position the B.M.A. advised the profession to take service under the National Health scheme, although a majority of votes was against it. Now the Association can see what they have let the profession in for. So can those members whose apathy throughout was such a handicap. I hope they are feeling the pinch! The fact that hundreds, if not thousands, of medical men and their families are faced with stark insolvency is surely a matter for concern not only of the profession but of the public.

We are dealing with a strike-minded Government who have prised their way to office by that method. Student nurses put up an exhibition which we all deplored, for the strike is an unthinkable weapon for use by the profession—whether nurses or doctors. But their action was understood by the Government and they got what they wanted, to the prejudice of nursing sisters of long service. Remember that.

The public must not be surprised if desperate men take desperate measures. I feel that the time has come for something to be done for our brethren who are in dire straits, and it must be done at once. The time for leisurely and interminable "negotiations" is past. If the Association can do no more to help than they have done in the past, other methods must be found. Are we going to stand by while so many are faced with ruin? What about it?—I am, etc.,

Brookwood, Surrey.

H. M. STANLEY TURNER.

Rural Practice

SIR.—The plight of many rural practitioners is as acute as any abdominal emergency, and prompt action is urgently needed to relieve their unhappy condition. With incomes reduced by anything up to half their value before July 5, it will be imperative for them to take drastic action if the Minister does not soon do something to remedy the situation. Panel work before July 5 was in this district subsidized by fees from private patients, and the slight increase in the capitation rate in the new scheme does not nearly make up for the loss of private fees, which have now almost disappeared.

Mileage rates must be sufficient to cover not only the heavy car expenses but also capitation fees lost by reason of smaller lists compared with urban districts. When it is necessary to cover 60 to 80 miles a day at least three or four hours are spent daily in travelling which might otherwise be spent actually seeing patients. Rents for outlying surgeries and heavier tele-

phone costs are among other expenses that must be taken into consideration. It is also necessary to visit many patients in the country who might attend the surgery in a town, because of lack of public transport.

We thoroughly agree with Dr. S. T. Pybus (*Supplement*, Oct. 16, 1948, p. 143) that all who think as he does should write to the B.M.A. We should like to add the urgent suggestion that the B.M.A. should do all it can to find out as soon as possible how many are financially affected and are willing to resign, so that concerted action shall be taken without delay. If all with similar ideas would write to their B.M.A. Divisional secretaries the required information could be easily obtained.—We are, etc.,

G. G. M. EDELSTEN.

F. G. LOUGEE.

Winchester.

SIR.—May I, as a "truly rural doctor," support all that has been written about our problems? May I also add that in many sparsely populated areas some of us have only 1,000 on our list. Further, these areas are often over-doctored, as in this area, by squatters who have not paid for any goodwill. Our chief source of income—our private practice—has almost ceased since July.

I also wish to raise a further point—namely, the case of those of us who were over 60 on July 5. We can earn no pension; service in the N.H.I. (30 years in my case) counts for nothing; we are not allowed to serve 10 years and yet are told no age for retiring is fixed. Would it not be reasonable and fair to allow us a pension after 5 years' service under the new Service, or in the event of retirement forced by ill-health?

Some of us owing to ill-health have suffered heavy financial loss—locum fees, nursing-homes, etc.—so that we cannot afford to retire. For example, in my case I have had to buy two practices owing to ill-health at two years' purchase and two houses, and at the age of 63 my overdraft is £3,500. There must be many worse off than I. Can we appeal to the B.M.A. to recognize our position and persuade the Minister to grant us a sufficient income for a doctor and his wife to be able to meet old age in comparative comfort—surely well earned?—I am, etc.,

SENEXIUS.

Obstetric Fees

SIR.—Surely there is a mistake in the answer under "Questions Answered" (*Supplement*, Dec. 18, 1948, p. 228) regarding attendance at confinements? According to my reading of the regulation, to qualify for the seven-guinea fee one must attend the mother and child during the puerperium and give post-natal care of the mother including a pelvic examination at or about the sixth week. I think it only reasonable that the full fee should be paid, but I feel very doubtful if it would be if strict adherence to the regulation was made, and the question cannot be so easily answered as you have done.—I am, etc.,

Farnham, Surrey.

G. HUMPHREY WARD.

* The answer given in the *Supplement* of Dec. 18, 1948, assumed that on discharge from hospital the patient received post-natal care and the prescribed pelvic examination from her own doctor.—ED., B.M.J.

Payment by Patients

SIR.—It is quite clear now that an immediate improvement in remuneration of the general practitioner must take place. Even in the relatively happy days of private practice the finances of the general practitioner were a source of constant anxiety to bank managers throughout the country. To-day, with the rising cost of living, we are faced with a reduction in our standard of living out of proportion to that borne by any other section of the community.

In order to make a last endeavour to maintain the personal relationship between practitioner and patient I suggest that the increase in remuneration be paid direct by the patient, either in the form of an additional yearly capitation fee, or preferably by a fee per visit, surgery attendances being free from any additional charge. In this way the practitioner who prefers to give more detailed attention to a smaller number of patients would have his reward, while the practitioner who prefers the larger number of patients would perhaps need to make only very

small additional charges. The patients would approve this scheme; it would help to remove the bitterness which is so widespread in our ranks; but what would be the attitude of the Minister?—I am, etc.,

Huddersfield

C. A. BARRETT.

Representation of Non-teachers

The following letter has been sent to the Chairman of the Negotiating Committee (with a request to the Editor that it be published in the "B.M.J.") in reply to a letter from the Chairman relating to the continued existence of the Committee.

Dear Dr. Dain,

I thank you for your letter of Dec. 23 relating to the disbanding of the Negotiating Committee, and I would like to express my gratitude to you for the immense trouble and care you have taken in presiding over this composite body that at times showed a certain centrifugal tendency.

While I have endeavoured to uphold the legitimate interests of those whom I represented—i.e., the Association of the Honorary Staffs of the Major (Non-Undergraduate Teaching) Voluntary Hospitals of England and Wales—I hope that my contributions to the deliberations of the committee were of value in a wider field.

For myself, having been a member appointed by the Council of the B.M.A. to represent non-teachers in the original Representative Committee in the time of Dr. Anderson's secretaryship, and having served in the Negotiating Committee which followed it, my feelings are rather mixed. I have done my share, and am glad of some relaxation; on the other hand I am sorry to be out of touch with contemplated changes. Furthermore, I am profoundly disturbed at the composition of the present body which claims to speak for consultants and specialists. Of seventeen members I understand that only six—i.e., those nominated by the B.M.A.—can in any sense be considered to have been elected democratically.

When the non-teachers were asked to meet the Provincial Teachers at B.M.A. House with a view to forming the new Consultants and Specialists Committee of the B.M.A., we, the non-teachers, gave away the major representation granted in the draft document, wherein it was suggested that the non-teachers, forming as they do the majority of consultants and specialists, were to have representation bearing some relationship to their numbers, and in order to attain unity we agreed to equal representation with the minority formed by the teachers. We did so under the belief expressed to us in the most authoritative way that this committee would be the committee, subordinate to no other body, that would represent the consultants and specialists in future negotiations. Its autonomy was stressed strongly.

Within a few weeks, however, a joint committee was set up, and this autonomous representative consultants and specialists committee of the B.M.A. had been reduced to a minority in the new joint committee. And that as far as non-teachers are concerned, only two of the six B.M.A. representatives do not hold appointments in undergraduate teaching hospitals.

We of the non-teaching hospitals have increasing reason to fear for our future, both as regards security of tenure as well as terms and conditions of service. Regional boards are more remote than boards of governors in relation to any particular consultant or specialist, who might have considerable difficulty in putting forward his case if he felt that he had been badly treated.

The Association which I represented in the Negotiating Committee is in process of reorganization to meet the new arrangements, and will continue to do its best to safeguard the interests of those employed by regional boards, and it is to me a matter of regret that, while other bodies such as the Colleges and Scottish Corporations are represented in the new joint committee, this Association, representing such a very large proportion of consultants and specialists, should be no longer represented in future negotiations.

In order that my constituents may be informed that they are no longer directly represented in the new body, I have asked the Editor of the *B.M.J.* if he will publish this letter.

Yours sincerely,

H. J. MCCURRICH.

Payment for Work Done

SIR,—We are unhappy doctors because we are attempting to work an unsatisfactory National Health Service under unsound conditions. We are in it against the better judgment of the majority of us, for even the ill-starred second plebiscite showed a good majority still not in favour of the National Health Service.

We ought never to have joined without having first secured sound and satisfactory conditions of work, but we suffered the cruel coercion of barefaced financial blackmail. The dentists had no such loss of capital value of practices to fear, and they held out against the Act after the appointed day. The result? A golden haul for the dentists.

There can be no satisfaction in work as arduous and responsible as medical practice until some relationship exists between work done and money received. The only result of continuing as at present is a steady and inevitable deterioration in the quality of our service. I suggest that the time of polite waiting for the fulfilment of promises—e.g., the honest application of Spens—is over. I suggest that a quick and satisfactory solution to our problems can be achieved by a mass threat to resign from the Service. It is apparently the only language understood by the Minister: he understood similar language in 1946 so promptly that a capitation fee of 15s. 6d. was offered (when only 15s. was asked) ere ever the controversy reached the Press, so that even to-day the public does not realize how close to collapse was the N.H.I. in its last lap.

We joined by July 5, thus establishing our right to claim compensation. Now let us threaten to resign unless our reasonable demands are met. We shall soon have nothing to lose.—I am, etc.,

Bridport, Dorset

J. MAXWELL JONES.

Payment for Services Rendered

SIR,—It is amazing that a profession trained in the art of scientific reasoning and the deduction of cause and effect should show itself so incapable of applying this training to political matters. The most striking example of this incapacity was the failure of the majority to appreciate the results which would flow from the introduction of a 100% "free" service instead of a 90% service with an income limit, as advocated by the minority. It should have been obvious to the lowest intelligence that if 100% of the population were compelled to contribute to National Insurance practically 100% would later seek to make use of it in the only way open to them, and whatever the Government may tell them to the contrary most people believe that their National Insurance contributions are paying for the "free" Health Service.

The argument was used that, because free education was available to everybody but not used to any great extent by the middle and upper classes, in the same way the free health service would be scorned, and that these "higher income groups" would remain private patients. A few moments' thought should have made anyone realize that the two services were in no way similar: in education, those who prefer to pay are satisfied that they are buying a superior type of education to that which is provided free by the State, whereas in the Health Service the free service is to be the best possible, so why pay twice over? Nevertheless, that this reaction was not anticipated by the bulk of the profession was proved by the various votes which always went in favour of a 100% service. Those who attended "group discussions" in their divisions soon after the Beveridge Report came out will remember how impossible it was to persuade the majority that they were wrong.

The result of this gross miscalculation is now to be seen in the plaintive letters from doctors in rural areas who find their high-class practices ruined and themselves rapidly approaching bankruptcy. How can it be otherwise if the people living at the Hall who never minded paying 25s. per visit have now joined the State Service and expect the same amount of attention for 18s. per annum?

What is to be the remedy? I would suggest that many of the people in the "higher income groups" who have joined the Service have done so unwillingly, and would be only too glad to contract out of National Insurance with all its "benefits" if that were allowed. The tide of Socialism is receding, and there

are many signs of a reaction. The time will come, perhaps soon, when we have a less theory-bound Government and one which may be glad to cut down national expenditure. Then will be the time to urge amendment of the National Insurance Act to allow anyone paying over a certain amount in income tax to contract out of the whole scheme and *ipso facto* to "cease insurance" and become private patients again. It will surprise the Government to find how many people will be glad to do so. One cannot believe that the principle of unwilling compulsion can prevail for long on British soil.

However, a more immediate remedy is called for, and it should be realized forthwith that no capitation system of payment covering the entire population can ever work out fairly as between the different types of practice. If the capitation fee were raised to £10 per head, no doubt those with small, select, and very widespread practices would find themselves no worse off than before; but of course those in crowded urban areas with a maximum list would be making £40,000 per annum gross—and I doubt whether any G.P. would suggest that he ought to compete with the heads of the legal profession.

In my view there should be a small capitation fee for registration of a patient—say 5s. per annum. This would be recognized as payment for maintaining a unit of the Service, and would perhaps cover the bulk of practice expenses. In addition there should be a fee for each item of service performed. If this can be done for maternity work and for dental fillings, etc., I see no reason why it could not be done for ordinary consultations and visits, with a sliding scale for the latter fixed by the character of the district. It would be a simple matter to fill up a small form at each attendance, which would be initiated by the patient, showing the charge according to a fixed scale—e.g. : visit + any necessary prescriptions and certificates 7s. 6d.; extra for injection of vaccine 3s. 6d.; consultation at surgery 5s., and so on. The bunch of forms would have to be sent in to a pricing bureau in the district each week, just as the chemists send in the prescriptions, and this would find useful work for girls displaced from the petroleum office no longer required after the termination of petrol rationing. A check on unnecessary visiting could be devised and operated by the regional medical officers and executive committees, and an added deterrent could be provided by making the patient pay the first 1s. of each fee, with exceptions for cases of unemployed and other forms of hardship. I hope this suggestion will receive careful consideration.—I am, etc.,

Coventry.

D. MURRAY BLADON.

Estimate of Income

SIR,—In my letter (*Supplement*, Dec. 25, 1948, p. 241) I gave figures to show that your assertion in the leading article in the *Journal* of Nov. 13 (p. 864) that "in an industrial country such as Britain the majority of general practitioners will receive the greater part of their income from what were formerly described as 'panel patients'" had no foundation in fact, and that therefore the inference drawn from it was unwarranted. Your comment (p. 241) that the total pre-war income of general practitioners was £28 millions was a mathematical computation by Professor Bradford Hill has no relevance to the very important point raised, and I can only suggest the obvious conclusion.—I am, etc.,

London, S.W.3.

MORRIS CUTNER.

Form a Trade Union

SIR,—I have read every letter which has appeared in the *Supplement* since July 5, 1948. They make very depressing reading, and this section of the *Journal* has almost become an agony column.

Two recent letters, however, stand out by reason of their more comprehensive grasp of the problem involved. I refer to the letters by Dr. R. E. Newman on remuneration (*Supplement*, Dec. 25, 1948, p. 239) and Dr. R. N. Deane's masterly and mathematical contribution (Jan. 1, p. 5) on remuneration and size of lists. I was especially interested in Dr. Deane's conclusion in paragraph 8 of his letter that 1,500 patients was the maximum to which any general practitioner could decently attend. I myself reached an identical conclusion several years ago by pure trial and error. For some years I have limited my patients approximately to this figure and find that I work 60

hours a week, even with very generous secretarial help, and that this is all the work I feel I can adequately do. I agree with Dr. Deane that as the patients under one's care exceed this figure the quality of one's work must deteriorate. To attend 2,500 patients is not medicine; to attend 4,000 is sheer tomfoolery.

I did not join the National Health Service on principle. To nationalize the family doctor is a catastrophe whatever argument there may be for the nationalization of hospital and other medical services. It is bad for the patient, bad for the doctor, and bad for the practice of medicine. Alas, like Esau of old, the medical profession has recently sold its heritage for a mess of pottage (security) and must now take the consequences. In my opinion the whole matter is irremediable, irreparable, and irreversible.

The best that can now be done is for the medical profession to accept the situation and quickly set about the formation of a trade union with power to strike and power to deal with blacklegs; to drive an increasingly hard bargain with the community, through its Government, for better pay and better conditions, as is now being done by most sections of the community. I admit that this would be a tragedy, but no greater tragedy than that which befell the profession on July 5.—I am, etc.,

Putney, Surrey.

C. E. TAYLOR.

Salaries of Tuberculosis Officers

SIR,—The claims of general practitioners for satisfactory rates of pay have been ably expressed in recent weeks, and the full weight of the B.M.A. is behind them. Last week we learnt that strong measures are also being taken to ensure that the needs of public health officers for a salary scale in line with present requirements are not to be ignored. May I now write on behalf of tuberculosis officers?

Until July 5 the salaries of T.O.s were related to public health salaries. Now T.O.s are mainly in the service of hospital regional boards. Details of future status are still unknown, but alarming rumours are current to the effect that most T.O.s will not be given specialist status, even although they may have been holding posts of clinical responsibility under their local authorities. These rumours are strengthened by the fact that in almost all recent advertisements for tuberculosis physicians the posts are classed "Assistant Chest Physicians" and carry a salary equal approximately to that which most T.O.s now get and which is generally regarded as inadequate.

A policy which placed most T.O.s in the category of "assistant" would effectually be in contradiction to the Spens Report, which stated that all specialties were to be regarded as of equal status. More important, the policy would cause such resentment as to interfere with the proper development of the tuberculosis service and the encouragement of future recruits.

I hope that these rumours are not founded on fact and that there is no intention of relegating tuberculosis work to an inferior status. I should welcome, of course, official comment and that of colleagues.

Finally, may I ask that, if one's worst fears are substantiated, tuberculosis officers should get the same support that other groups of the profession are obtaining?—I am, etc.,

Welwyn Garden City, Herts.

B. COLTS

Dictatorial Action

SIR,—I am forwarding a copy of a letter received from the Executive Council for Cheshire in reply to my application for basic salary. I have forwarded a copy of the letter to the Minister of Health, etc.

"Your claim for the payment of the basic salary at the rate of £300 per annum for the quarter ending Dec. 31, 1948, has been duly considered by the Executive Council after consultation with the Cheshire Local Medical Committee and after submission to the Joint Consultative Medical Committee.

"The Executive Council resolved that your application be disallowed on the grounds that you failed to submit the requisite information upon which to enable the Council to arrive at a considered decision."

It will be noted that requisite information was not requested by the executive council prior to refusing my application for basic salary. If this dictatorial action is typical of the State medical service, how can doctors be expected to co-operate in

making it a success? As a member of the B.M.A. I demand that action be taken, and the widest publicity given to this case.—I am, etc.,

Meols, Cheshire.

E. S. A. ASHE.

Marriage Allowances for Medical Officers

SIR,—No one affected by the Government's decision to increase the taxable allowances of serving officers other than those on a temporary engagement will fail to realize that this differential treatment is in fact a financial inducement to conscripted medical and dental officers to apply for permanent commissions in the Services. Dr. E. J. Trimmer (*Supplement*, Jan. 1, p. 8) suggests that this is unjust.

It would appear, however, that it is perfectly reasonable for an employer to pay more to a member of his staff on a voluntary long-term contract than to a conscripted locum. Where an injustice was committed was in the Government's deciding to ignore the fact that the high cost of living applies to both permanent and temporary officers' families for fear of falling into the trade union heresy (*sic*) of abandoning the principle of the rate for the job.

The unmarried conscript officer is not financially differentiated from the unmarried regular. Once more the Government hits the person who complains least in the way that hurts most—the housewife through her family budget. It would be interesting to know how much money is saved by this cheese-paring discrimination.—I am, etc.,

London W 2

J. B. LOUDON.

POINTS FROM LETTERS

Allowance for Drugs

Dr. J. M. RAPHAEL (London, S.W.5) writes: In his letter on "Drugs Stocked by Doctors" (*Supplement*, Dec. 25, 1948, p. 238) Sir Ivor Beauchamp refers to an allowance of 2s. 6d. per 100 persons on doctors' lists for drugs administered in person. A few weeks ago I raised this question in correspondence with the London Executive Council, and this is the Council's reply *verbatim*: "There is no form for ordering a supply of drugs a practitioner is required to administer in person. This is covered by an extra allowance of 1s. per hundred patients, which is made to all medical practitioners." Is there any reason for the discrepancy between Sir Ivor Beauchamp's and the official figures? . . .

** The executive council seems to have made a mistake.—ED., B.M.J.

Just Claim Not Met

Dr. SYDNEY J. BELLGARD (Cardiff) writes: A good many medical men are at present going through a very precarious time, and I suggest that representations should be made to the Minister to meet their financial distress by payment of their full compensation. Why should anybody have to wait until his 65th birthday to claim his full compensation? . . . The position lies now with the doctors themselves. We have tried to obtain our requirements by democratic means without success. It is quite obvious that the terms of granting of the basic salary were only a red herring to divide the profession. I feel that he has practically been successful. I regret to say that reading through some of the articles published weekly in the *British Medical Journal* some medical men are quite indifferent to the plight of their less fortunate comrades and extremely selfish in their attitude. The medical profession must work as a team and must follow the lines of the trade unions. If any member of the trade union is unjustly treated a strike is called to meet the situation. The doctors have a just claim, which has not been met, so the alternative is to resign. The medical representatives should clearly place the facts before the Minister with the option of mass resignations from the Service. The doctors want the Service to work on an equitable basis, and not as a lackey to its auxiliary services. . . .

Master Minds

Dr. R. E. M. COKE HARVEY (Berkhamsted, Herts) writes: Your annotation in the *Journal* of Jan. 1 (p. 23) was indeed an eye-opener. . . . The anger your article aroused in me has prompted the question, How long is the medical profession prepared to endure such taunts, threats, sneers, if not actual ill-treatment, without doing something about it? Are we doctors to be the worm that never turns? The lesson is easy. Had the position been reversed organized Labour would by now have forced the rash speaker to eat his words or worse. . . . Our masters have achieved their present positions of power and influence through adherence to the principle of strength through union and unhesitating use of the threat of force at no matter what inconvenience to the general public.

Doctors, with far greater potential power than ever Labour had, will deserve to become actual serfs if they cling to the ethereal ethic of an age outworn, however noble and good in its time, in the brutal, striving, loveless, realistic world of to-day. . . .

Ophthalmic Service: Correction

Dr. LESLIE HARTLEY (Camberley, Surrey) writes: In my letter on the Ophthalmic Service (*Supplement*, Jan. 8, p. 18) I should have stated that when "the refraction fee for a patient for ophthalmic medical practitioners had been cut from £1 11s. 6d. to 12s. 6d. for school clinics it seemed a little strange that the optician who measured the patient for glasses should continue to receive £1 5s. 6d. for this service. . . ." I should be grateful if you could correct this error, as the fee has so far only been cut in the case of school clinics.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils—Fulham, Hackney, Poplar.

Non-County Borough Councils—Dartford, Radcliffe (limited to future appointments), Wallsend

Urban District Councils—Denton, Droylsden, Houghton-le-Spring, Hutton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

H.M. Forces Appointments

ARMY

Major Generals Sir Gordon Wilson, KCSI, CB, CBE, MC, late R.A.M.C., Sir Robert Hay, KCIE, late I.M.S., retired, and Sir G. G. Jolly, KCIE, I.M.S., retired, have been granted the honorary rank of Lieutenant-General.

Brigadier (Temporary Major-General) F. Harris, CBE, MC, K.H.S., late R.A.M.C., to be Major-General.

Colonel J. M. Macfie, CBE, MC, late R.A.M.C., to be Brigadier.

Colonel D. C. Bowie, OBE, late R.A.M.C., to be a Consultant and has been granted the local rank of Brigadier.

Colonel F. D. Annesley, MC, late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Brigadier.

Colonels F. S. Gillespie, J. H. C. Walker, G. D. Carr, MC, C. O. Shackleton, R. McKimley, OBE, J. A. Crawford, J. Biggam, MC, K.H.P., and D. W. Beamish, MC, late R.A.M.C., have retired on retired pay.

Colonels E. M. Townsend, MC, and G. D. Gripper, late R.A.M.C., having attained the age for retirement, are retained on the Active List supernumerary to Establishment.

Colonels J. Biggam, MC, K.H.P., and T. F. Kennedy, OBE, late R.A.M.C., having completed four years in the rank have been retained on the Active List supernumerary to establishment.

Lieutenant-Colonels F. C. Hilton-Sergeant, W. R. D. Hamilton, OBE, R. Murphy, A. M. Simson, F. J. O'Meara, R. J. Rosie, K. Fletcher-Barrett, OBE, J. Huston, C. W. Greenway, and L. Handy, from R.A.M.C., to be Colonels.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel R. C. Clarke, OBE, T.D., having attained the age limit has relinquished his commission and has been granted the honorary rank of Colonel. (Substituted for the notification in a Supplement to the *London Gazette* dated July 2, 1942.)

Major J. B. S. Guy, CBE, T.D., has been granted the acting rank of Colonel.

War Substantive Major (Temporary Lieutenant-Colonel) M. H. Evans, MBE, to be Major.

Captain (War Substantive Major) G. G. Farrington to be Major. Captain B. F. Longbottom to be Major. (Substituted for the notification in a Supplement to the *London Gazette* dated Dec. 7, 1948.)

Captains J. L. Fraser, G. E. W. Wolstenholme, OBE, and J. H. Whittles to be Majors.

Captains K. H. Smith and J. H. Dean to be Acting Majors.

Lieutenant J. Donovan to be Captain and has been granted the acting rank of Colonel.

Lieutenants P. G. McGrath and M. J. G. Lynch to be Captains and have been granted the acting rank of Major.

Captain J. G. Bourne, Reserve of Officers, to be Captain.

Captain H. C. Miller has relinquished his commission on account of disability and has been granted the honorary rank of Captain.

Lieutenant (War Substantive Captain) D. W. L. Leslie to be Captain, and has been granted the acting rank of Major.

Lieutenant S. F. Seelig to be Captain and has been granted the acting rank of Major. (Substituted for the notification in a Supplement to the *London Gazette* dated Aug. 20.)

Lieutenants P. Jacobs, W. Rankin, J. Petrie, D. K. W. Picken, H. V. Roberts, T. G. Lowden, J. P. D. Bates, K. H. Smith, J. J. A. Reid, A. B. Tompkins, J. H. Challenger, A. C. D. Parsons, F. W. E. Rutter, J. Nicholson, and N. D. H. Hennehan to be Captains.

H. M. Price to be Lieutenant.

INDIAN MEDICAL SERVICE

Colonels H. M. Strickland and L. K. Ledger, CIE, OBE, have retired.

Lieutenant-Colonel A. H. Craig has retired and has been granted the honorary rank of Brigadier.

Lieutenant Colonel B. P. Baliga, OBE, to be Colonel.

Lieutenant-Colonels F. M. Collins, G. M. Irvine, P. L. O'Neill, E. P. N. M. Early, H. T. McWilliams, G. H. Fraser, C. V. D. Rose, A. V. O'Brien, and V. E. M. Lee, MC, have retired and have been granted the honorary rank of Colonel.

Lieutenant-Colonels J. E. Gray, F. E. B. Manning, K. F. Alford, S. R. Prall, P. L. O'Neill, M. R. Sinclair, OBE, P. R. Vakil, E. M. Sewell, and B. G. Mallya have retired.

Majors (War Substantive Lieutenant-Colonels) V. D. A. Blackburn, P. J. Franks, W. Mackie, C. W. Greene, W. L. Fennell, OBE, P. N. McSwiney, J. J. Barton, J. W. R. Sakies, T. K. White, and J. Edis have retired and have been granted the honorary rank of Colonel.

Majors N. I. McLeod, L. U. Camm, J. H. Walters, W. Laurie, D. S. O. R. J. Henderson, E. J. Crowe, OBE, J. G. Statham, W. J. Stewart, W. W. Coppinger, R. J. McGill, T. Denress, J. H. Bowie, A. D. Barber, G. F. J. Thomas, J. Duffin, R. J. Jarvie, W. S. Davidson, L. D. B. Frost, F. C. Gnggs, D. W. Taylor, F. J. Doherty, R. D. Ewing, B. de Burca, MBE, G. E. S. Stewart, MBE, S. G. O'Neill, F. E. McLaughlin, and E. C. Hicks have retired, and have been granted the honorary rank of Lieutenant-Colonel.

Major H. J. Gibson has retired.

Captains (War Substantive Majors) F. W. Sneddon, OBE, W. S. Hacon, H. F. T. MacFetridge, DSO, L. H. Cooper, and R. M. McCullough have retired and have been granted the honorary rank of Lieutenant-Colonel.

Captain (War Substantive Major) R. O. Yebury has relinquished his commission on appointment to the R.A.F.

Captain N. A. Michael has retired.

The surname of Lieutenant Colonel R. C. Wats is as now described and not as notified in a *London Gazette* dated July 30, and in the Supplement to the *Journal* dated Aug. 28 (p. 98).

EMERGENCY COMMISSION

Captain A. E. Evans has relinquished his commission and has been granted the honorary rank of Major.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: J. D. R. Perkins, LMSSA, Medical Officer, Tanganyika; C. E. Gordon Smith, MB, Medical Officer, Federation of Malaya; J. L. Q. Vanderpuje, LRCS, LRFPs, Medical Officer, Nigeria; H. R. Wilson, MB, Woman Medical Officer, Northern Rhodesia; H. M. S. G. Beadnell, LRCP, Assistant Superintendent, Mental Hospital, Barbados; A. M. Dunn, MRCS, Medical Officer Grade C, Trinidad; J. M. Hagen, MB, House Surgeon, Federation of Malaya; C. R. Jones, MB, Medical Officer, British Guiana; F. A. Pearson, MRCS, Temporary Medical Officer, Nigeria; P. I. Boyd, MD, Medical Officer of Health, Leeward Islands; E. J. Bury, MRCS, DTM&H, Senior Health Officer, Nigeria; J. Cook, FRCS, Surgical Specialist, Hong Kong; R. S. F. Hennessey, MD, MRCP, Deputy Director of Medical Services, Uganda; H. R. Hudd, MB, Medical Officer, Uganda; F. McLagan, MB, MRCP, Director of Medical Services, Sierra Leone; D. J. A. McLean, MB, Medical Officer, Nyasaland; S. L. A. Manuwa, FRCS, Regional Deputy Director of Medical Services, Nigeria; W. E. S. Merrett, MB, Principal, Medical School, Nigeria; D. Murray, MB, DPH, Regional Deputy Director of Medical Services, Nigeria; M. A. Byers, MB, Senior Medical Officer, St. Lucia; R. O. Cooke, DM, MS, Senior Medical Officer, Mental Hospital, Jamaica; K. C. Royes, MRCS, Medical Officer, Mental Hospital, Jamaica; L. R. Wynter, DM, Ophthalmic Surgeon and Assistant Medical Superintendent, Leeward Islands.

Association Notices

FORMATION OF MANICLAND BRANCH

The Council of the Association has formed a Manicland Branch in the area of Southern Rhodesia. The new Branch comes into existence as from the date of publication of this notice.

CHARLES HILL,
Secretary

NATHANIEL BISHOP HARMAN PRIZE

The Council of the British Medical Association is prepared to consider the award of the Nathaniel Bishop Harman Prize in the year 1949. The value of the prize is approximately £100. The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has been previously published in the medical press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1949 but will be offered again the year next following this decision, and

in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

The writer of the prize-winning essay may be required to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association. Each essay must be typewritten or printed in the English language, and must be distinguished by a title and a motto. The essay must not bear the name of the writer, which should be sent with the essay in a sealed envelope, bearing only the motto on the outside.

Essays must be forwarded to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than March 31, 1949. The title of the proposed essay and the motto should also be notified in writing to the Secretary by Dec. 1, 1948, and should not be accompanied by the writer's name. The prize will be awarded at the Annual Meeting of the Association to be held in 1949. Inquiries relative to the prize should be addressed to the Secretary.

PRIZES FOR MEDICAL STUDENTS

The Council of the British Medical Association is prepared to consider the award in 1949 of prizes to medical students for essays submitted in open competition. The subject of the essays for 1949 shall be: "The Value of Observation in the Training of the Medical Student." The purpose of these prizes is the promotion of systematic observation among medical students. In awarding the prizes *due regard will be given to evidence of personal observation*. No study or essay that has previously been published in the medical press or elsewhere will be considered eligible for a prize.

The following prizes are offered:

National Prizes—six, each of the value of £25.

Regional Prizes—as detailed below, based on the four Regions of the British Medical Students Association:

London Region, 6 prizes (1 of the value of £15; 5 of the value of £7).

Midland Region, 3 prizes (1 of the value of £15; 2 of the value of £7).

Northern Region, 3 prizes (1 of the value of £15; 2 of the value of £7).

Scottish Region, 5 prizes (1 of the value of £15; 4 of the value of £7).

Any medical student who is a registered member of a medical school in Great Britain or Northern Ireland at the time of submission of the essay is eligible to compete for the prizes. The winners of the National Prizes will be ineligible for the award of a Regional Prize. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final. Should the Council of the Association decide that no essay entered is of sufficient merit, no awards shall be made.

Each essay must be typewritten or written legibly in the English language, and must be unsigned and accompanied by a detachable sheet giving the name of the candidate, his medical school, and his B.M.S.A. Region. Essays must be forwarded so as to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than March 31, 1949.

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for research scholarships as follows: An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1, 1949. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the award of the Insole Scholarship of the value of £250 for research into the causes and cure of venereal disease.

Applications for scholarships must be made not later than March 31, 1949, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

PRIZES FOR NURSES

The Council of the British Medical Association is prepared to consider the award in 1949 of three prizes each of the value of 20 guineas for the best essay and three prizes each of the value of 10 guineas for the second best essay submitted in open competition by each of the following categories of nurses: (i) Pupil nurses; (ii) State-registered nurses working in a hospital; (iii) State-registered nurses not working in a hospital—i.e., district nurses, private nurses, etc.

The subjects of the essays for 1949 shall be: category (i), "What discipline do you think necessary in the training of nurses?"; category (ii), "What part of nursing duties can be delegated to others with safety?"; category (iii), "The care of old people in their own homes."

The purpose of these prizes is the promotion of systematic observation among nurses. In awarding the prizes *due regard will be given to evidence of personal observation*. No essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Nurses who are undergoing training at a hospital are eligible to compete under category (i); nurses registered by the General Nursing Council are eligible to compete under categories (ii) and (iii). If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. Should the Council decide that no essay entered is of sufficient merit, no award shall be made. Each essay must be typewritten or legibly written, must be unsigned, and must have attached to it a sealed envelope containing the name and address of the candidate and the category into which he or she falls. Essays must reach the Secretary of the British Medical Association not later than March 31, 1949. Inquiries about the prize should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

Diary of Central Meetings

JANUARY

27 Thurs. Publishing Subcommittee, 11 a.m.

Branch and Division Meetings to be Held

AYRSHIRE DIVISION.—At Ayrshire Central Hospital, Sunday, Jan. 16, 7 p.m. Professor Matthew Stewart: "A Pathological Pot-pourri."

GREENWICH AND DEPTFORD DIVISION.—At St. Alfege's Hospital, 48, Vanbrugh Hill, London, S.E., Wednesday, Jan. 19, 8 p.m. Clinical meeting. Members of the Woolwich Division are invited to attend.

METROPOLITAN COUNTIES BRANCH.—In the Great Hall, B.M.A. House, Tavistock Square, London, W.C., Thursday, Jan. 27, 8 p.m. Address by Dr. Charles Hill: "Terms of Service."

STOCKTON DIVISION.—At Stockton and Thornaby Hospital, Bowesfield Lane, Stockton-on-Tees, Monday, Jan. 17. B.M.A. Lecture by Dr. Wilfred Sheldon: "Stomatocoe in Childhood." To be preceded by supper at 7 for 7.15 p.m.

SUNDERLAND DIVISION.—At Sunderland Royal Infirmary, Friday, Jan. 21, 8 p.m. Address by Dr. G. D. Kersley (Bath).

WEST MIDDLESEX DIVISION.—At Town Hall, Ealing, Friday, Jan. 21, 8.30 p.m. Clinical film: "Studies in Human Fertility."

WESTMINSTER AND HOLBORN DIVISION.—At Westminster Children's Hospital, Vincent Square, London, S.W., Thursday, Jan. 20, 5 p.m. Clinical meeting. Demonstrations and photographs: (i) hare lips and cleft palates; (ii) whooping-cough, diagnosis. Dr. Anderson: "Treatment in Congenital Heart Disease." Dr. Dean: "Early Diagnosis of Erythroblastosis." Dr. Norman: "Out-patient Treatment of Gastro-enteritis."

Meetings of Branches and Divisions

COVENTRY DIVISION

The B.M.A. Lecture for 1948 was delivered by Mr. R. C. Brock at the Coventry and Warwickshire Hospital on Dec. 14, 1948. The subject was "The Present Position of Thoracic Surgery." The chair was taken by Dr. A. F. Wright, chairman of the Coventry Division. More than 50 members of the Division were present, and among the visitors was Mr. Pracey, president of the Birmingham Branch.

Mr. Brock began with an anatomical survey of the main bronchi and discussed and illustrated the importance of the bronchial direction in the causation of lung abscess. He commented on the increased incidence of intrathoracic neoplasm in all classes of the community, and indicated the possibilities of surgery in its treatment. Pulmonary tuberculosis and its treatment by thoracoplasty was considered and Mr. Brock emphasized the great importance of its use in suitable cases. The problems, the achievements, and the potentialities of cardiac surgery were also considered. The lecture was illustrated by lantern slides and Mr. Brock replied to questions asked by the audience. The audience showed their appreciation in an enthusiastic vote of thanks, which was proposed by Mr. Pracey.

gushed violently from the vein. In some of the later cases venous pressure was measured as follows:

With the infant supine on a flat surface, a plastic catheter was passed up the umbilical vein for a distance of approximately 2½ in. (6.25 cm.); a little blood was withdrawn and the catheter was then connected to a fine-bored saline manometer. The level of saline in the manometer was raised above the expected venous pressure and allowed to run in slowly until equilibrium was attained and the infant was quiet. The readings were referred to the level of the lower part of the front of the chest, using a wooden rule and spirit level.

Results: A. Haemoglobin Values

Normal Infants

(a) *Cord Blood.*—The results of 52 tests on normal infants are plotted in Chart 1; their mean value was 16.35 g.% and their

CHART 1.—Hb values in normal infants and in infants with haemolytic disease. I, cord blood; II, venous blood taken a few hours after birth. In II, series "A" are affected infants whose cord Hb is also plotted in I. Series B are infants whose cord Hb was not determined.

S.D. 1.34. The normal range throughout this paper has been expressed as "observed mean ± 2 S.D.," which gives a calculated range of 13.7–19.4 g.%, rather than the observed range of 14–19.4 g.%.

(b) *First Day; Venous Blood.*—The mean of 43 observations was 18.45 g.% (S.D.=2.04); these observations are also plotted in Chart 1. Again the calculated normal range (mean ± 2 S.D.) has been considered as the normal range in this paper.

(c) *First Day; Capillary Blood.*—The mean value of 33 observations* was 19.1 g.% (S.D.=1.84).

(d) *Changes in Individual Cases.*—In Chart 2 the changes in four selected cases are illustrated. It will be noted that when the cord is tied late the haemoglobin value a few hours after

birth is considerably higher than that of cord blood, whereas when it is clamped immediately after birth there is little or no rise in the haemoglobin value. (For detailed observations upon this phenomenon, see De Marsh *et al.*, 1942; these illustrative normal cases are described because they have such a very important bearing on the changes observed in the affected infants.)

CHART 2.—Four normal infants selected to illustrate the effects of early and late tying of the cord.

(e) Haemoglobin Values After

the First Day of Life.—Only a small group of normal infants was tested at intervals during the first 60 days of life. No infant had a haemoglobin value of less than 11 g.% during this period.

Affected Infants

(a) *Cord Blood.*—Thirty infants were tested; 14 had value within the normal range and 16 had values below it, ranging from 3.4 to 12.8 g.%. No deaths occurred among the infants with normal values, whereas there were 10 deaths among the 16 anemic infants. Moreover, among the 10 infants with cord haemoglobin values below 8 g.% there were only two survivors (see Chart 1).

(b) *First Day; Venous Blood.*—Forty-three infants were tested; 14 had values within the normal range and 29 had values below it, varying from 3.7 to 14.3 g.%. These 43 cases included 23 whose cord-blood haemoglobin had been determined. As expected, the first-day values were on the average higher. At the same time the difference was a small one, and this was probably because in many instances the cord had deliberately been clamped as soon after birth as possible.

There were two cases of special interest: two infants whose cord-blood haemoglobin had been 12.3 and 12.8 g.% were found a few hours later to have values of 15 and 15.4 g.% respectively. Thus these two infants had values definitely below the normal range in cord blood, but a few hours after birth, doubtless owing to the fact that they recovered a fair amount of placental blood they had values within the normal range; that is to say, haemoglobin values no lower than that of a normal infant recovering little or no placental blood.

Of the 20 infants whose cord blood was not tested but from whom a venous sample was taken a few hours after birth four died subsequently; the haemoglobin value of all these four infants was below 12 g.%.

(c) *First Day; Capillary Samples.*—In a few infants capillary samples were taken at the same time as venous samples; as in normal infants, the capillary samples gave distinctly higher values.

In Chart 3 are plotted the haemoglobin values observed in one affected and one normal infant. The affected infant is one of the two mentioned above

whose cord haemoglobin value was 12.8 g.% and whose first-day venous haemoglobin value was 15.4 g.%; capillary samples taken at the same time as the "first-day venous" sample showed a further rise to 18 g.%. Thus it is clear that a haemoglobin value of 18 g.% in a capillary sample taken from an infant a few hours after birth does not exclude the possibility that a definite anaemia existed at the moment of birth.

The normal infant's cord haemoglobin value was 2.4 g.% higher than that of the affected infant, but because it recovered little placental blood its venous and capillary haemoglobin values a few hours later were no higher than those of the affected infant.

CHART 3.—The Hb value of a normal infant may rise from 12.9 to 15.4 g.% within a few hours of birth, owing to the transfer of placental blood; on the other hand, the Hb value may change only from 15.2 to 15.8 g.% in an infant who receives a negligible amount of placental blood. The difference between the two infants is thus temporarily masked. Capillary samples usually give considerably higher values than venous samples and thus further mask anaemia.

*This group of observations is not strictly comparable with (b). Direct comparisons on the same infants have revealed distinctly greater differences between capillary and venous samples.

(d) *Haemoglobin Values After the First Day of Life.*—Seven infants with cord haemoglobin values between 15.1 and 18.7 g.% were left untreated; two other infants seen for the first time during the first three days of life were also judged to be very mildly affected (haemoglobin value within the normal range, mild icterus, weak positive direct Coombs reaction) and were not treated; one further infant was first seen on the 30th day of life and then found to have a moderately strong positive direct Coombs reaction. This infant was known to have shown no trace of jaundice in the neonatal period. The haemoglobin changes during the first two months of life in these ten mildly affected infants are plotted in Chart 4. In

CHART 4.—Hb changes in 10 very mild cases of haemolytic disease. Cord blood: range, 15.1–18.7 g.% (7 cases tested); 30-day venous sample: range 8.2–18 g.% (10 cases tested).

addition, an indication is given of the time for which the direct Coombs test remained positive. It is clear that an infant can have a positive direct Coombs reaction for one and even two months after birth without developing any serious degree of anaemia, and can have a positive reaction for two to three weeks without developing any subsequent anaemia at all.

In the cases treated by exchange transfusion the infant was usually provided with a concentration of some 4–5.5 million Rh-negative erythrocytes per c.mm., and this population of cells disappeared at the rate of only 1% a day (with a single exception). Only in two cases in which the infant grew unusually rapidly and in two cases in which the infant was provided with a concentration of less than 3.5 million Rh-negative cells per c.mm. did the haemoglobin concentration subsequently fall to such a level (7 g.%) that it was considered necessary to give a further transfusion. In the remaining infants the haemoglobin fell to 8.5–10 g.% at the end of 30–60 days and then slowly rose spontaneously.

B. Erythroblastaemia

In 49 affected infants a blood film was examined on the first day of life. In 16 cases there were less than 10 nucleated red cells per 100 white cells; in 11 of these 16 the cord haemoglobin had been estimated and in only two the value below 15 g.% (in these it was 12 and 12.9 g.%). In the remaining five infants, examined a few hours after birth, the haemoglobin varied from 11.6 to 16.9 g.%. All of these 16 infants recovered uneventfully, some without treatment.

In the remaining 33 cases there were at least 20 nucleated red blood cells per 100 white blood cells; in many instances the nucleated red cells far outnumbered the leucocytes and there were numerous primitive forms. Fifteen of these 33 infants died and the remaining 18 all required treatment.

C. Bilirubin Values

Normal Infants.—Cord blood. Twenty-one normal infants were found to have a mean value of 1.6 mg. per 100 ml. with a range of 0.8–2.6 mg.

Affected Infants.—(a) *Cord Blood.*—Thirty-two infants were tested; values ranged from 1 to 9.3 mg. per 100 ml. (see Chart 5).

Amongst 11 infants with cord bilirubin values over 4 mg. per 100 ml. there were six deaths. There were only two deaths amongst the 13 infants with bilirubin values between 3 and 4 mg. per 100 ml., and all of the eight remaining infants with values below 3 mg. recovered uneventfully. (b) *First Few Days of Life.*—In the 7 mildly affected infants (referred to above) whose cord haemoglobin lay between 15.1 and 18.7 g.% and who were left untreated, bilirubin values rose from 1–3.2 mg. per 100 ml. in the cord blood to peak values of 1.3–15.8 mg. between the second and fifth days of life.

It is difficult to make useful comparisons between this group of cases and those whose blood had a low haemoglobin value on the first day of life, because the latter infants were treated by exchange transfusion. However, it was striking that in this group the five infants who died at the age of 2–5 days became profoundly jaundiced despite exchange transfusion, and as early as 24 hours after birth showed bilirubin values between 17 and 21 mg. per 100 ml.

In one infant (which did not develop kernicterus) exchange transfusion was not carried out until it was 12 hours old; during this period the plasma bilirubin rose from 8.1 to 19.3 mg. per 100 ml.

It is obvious that for purposes of comparison it is essential to take cord samples rather than samples a few hours after birth.

Correlation Between Haemoglobin and Plasma Bilirubin Values in Cord Blood

In Chart 6 the haemoglobin and plasma bilirubin values of the cord blood of 24 infants are plotted against one another. It will be noted that there is a correlation between low haemoglobin and high bilirubin values. As expected, the relationship does not appear to be linear. The haemoglobin value doubtless reflects the rate of blood destruction, so that, in general, higher bilirubin values are to be expected when the haemoglobin is low. Nevertheless the amount of bilirubin produced also depends upon the total amount of breaking-down haemoglobin, so that some falling off will be expected when the haemoglobin values are very low. From the Chart it appears that this is the case.

In Chart 6 the infants who died subsequently have been specially marked. It will be noted that there is some suggestion that the bilirubin value and haemoglobin value of a sample of cord blood, when taken together, give a better indication of the prognosis than either value considered separately. A slanting line could be drawn through the observations in such a way as almost completely to separate the living from the dying.

D. Serological Tests

Direct Coombs Test.

Tests were made on 69 Rh-positive infants born to mothers whose serum contained anti-Rh; all gave positive reactions, though a small number were weak. These weak reactions were shown by infants born to mothers

CHART 5.—Cord bilirubin values in 32 affected infants compared with a group of 21 normals.

CHART 6.—Cord Hb concentration plotted against cord plasma bilirubin concentration in 24 affected infants.

whose sera contained low-titre albumin antibodies or saline antibodies of low or moderate titre. Further tests were made from time to time during the first three months of life. The results obtained in the untreated cases are shown in Chart 4, and it will be noted that even in mild cases the reaction remained positive for at least 10 days after birth and that in some cases it remained positive for as long as 60 days.

In infants treated by exchange transfusion with Rh-negative blood, Rh-positive cells often disappeared completely within a few days of transfusion or fell to a level of approximately 250,000 cells per c.mm. In these cases the direct Coombs test became negative and did not usually become positive again even when, at the end of 50 or 60 days, there were once more large numbers of Rh-positive cells in the circulation.

In infants treated by simple transfusion of Rh-negative blood there were usually more Rh-positive cells persisting in the circulation, and the direct Coombs reaction remained positive for long periods after transfusion. In one exceptional case the test was still positive 93 days after birth.

Tests for Free Antibody in Infant's Serum.—The sera of 41 infants were examined, either by the indirect Coombs test or by titration in albumin, or by both methods, for the presence of free Rh antibody; one or the other, or both, of the tests was positive in 35 cases.

In 18 cases sera were examined by both tests; in two cases where the infant's serum had a titre of only 2 in albumin the indirect Coombs reaction was negative, and in one case in which the serum gave a weak positive indirect Coombs reaction antibody could not be detected by the albumin test. In the remaining 15 cases the two tests were in agreement.

The amount of free antibody, determined by albumin titration, was not well correlated with the clinical manifestations. For example, amongst eight infants with a titre of 2 or less, three died, four were moderately severely affected, and one was very mildly affected and required no treatment. Among seven infants whose sera had an anti-Rh titre of 16 or more, four died, two were severely affected but recovered, and one was very mildly affected and required no treatment.

Persistence of free antibody does not by itself appear to be associated with tissue damage. In one infant given repeated simple transfusions of Rh-negative blood no Rh-positive cells could be detected between the 14th and the 30th days of life; at the end of this period the infant's plasma still contained Rh antibody to a titre of 32. By the 60th day there were once more many Rh-positive cells present, the direct Coombs reaction was positive again, and there was now only a trace of free antibody. The infant finally recovered completely.

Titre of Rh Antibody in Mother's Serum.—In 62 cases a sample of blood was taken from the mother within 24 hours of delivery. In every case the serum was titrated against CDe/CDE cells both in saline and in albumin. Seventeen of the 62 sera reacted equally well in saline and albumin (i.e., difference no greater than one tube). The remaining 45 sera gave higher titres in albumin; 26 of these gave no reaction at all in saline and 19 reacted only in the first tube or the first and second tubes of the saline titration. The remaining 10 sera had titres of between 4 and 32 in saline, but in each case had an albumin titre that was at least four times greater (i.e., more than two tubes higher in the titration).

It is clear that any simple classification of these results must be arbitrary, but it is convenient to consider Rh antibodies in two groups—namely, (1) "predominantly saline agglutinins" (i.e., reacting equally well in saline and albumin): 17 cases; and (2) "predominantly albumin agglutinins" (i.e., titre in albumin two tubes or more higher than titre in saline): 45 cases.

It was noted that amongst the 17 cases in which the mother's serum contained predominantly saline agglutinins there were no stillbirths or deaths within the first 24 hours. However, there were three deaths at the age of 2–5 days, presumably from kernicterus. Amongst the 45 cases in which the mother's serum contained albumin antibodies (predominantly) there were four stillbirths, seven deaths within the first day of life, and four deaths at 2–5 days.

On these figures the difference in total mortality between the group of infants whose mothers' serum contained saline agglu-

tinins (mortality 18%) and the group in which the mother's serum contained albumin agglutinins (mortality 33%) cannot be considered significant (S.E. of difference = 12.6%). Nevertheless the absence in the "saline group" of stillbirths and death within the first 24 hours of life is significant. The milder effect of saline agglutinins are further emphasized by Chart 7.

CHART 7.—Titre of Rh antibody in mother's serum (at delivery) plotted against infant's first-day venous Hb value in 43 cases.

which the kind of antibody predominating in the mother's serum, and its titre, have been plotted against the infant's first-day haemoglobin value. It will be noted that in 10 out of 12 cases in which the mother's serum contained saline agglutinins the infant's haemoglobin value was above 14 g.%. With regard to sera containing albumin agglutinins predominantly, it appears that there is a correlation, though a poor one between titre and degree of anaemia. There are few low haemoglobin values occurring with low maternal anti-Rh titres and few normal haemoglobin values occurring with high maternal anti-Rh titres. That this correlation is significant can be shown by dividing the cases into groups having, for example, an albumin titre of 128 or more and 64 or less respectively, and showing that there is a significant difference in mortality. When the cases were analysed in this way and stillbirths (not appearing in Chart 7) were included, the results shown in Table II were obtained.

TABLE II.—Relation Between Titre of Albumin Agglutinins in Mother's Serum and Infant Mortality

Group	Total	Mother's Titre	Infants		Mortality
			Living	Dying	
I	23	1–64	22	6	21%
II	16	128 and over	5	11	69%

Observed difference between I and II = 48%. S.E. of difference = 14%.

E. Venous Pressure

Venous pressure was measured in 14 infants; in infants without anaemia or with only slight anaemia it was found to vary between +3 and +5 cm. of saline. It is to be noted that this is the pressure below the diaphragm, in the proximal part of the umbilical vein, and represents the pressure above the front of the chest. In infants with severe or moderate anaemia the venous pressure was usually raised, values of +9 to +11 cm. usually being recorded (Table III). In these latter cases the cord often bled violently when cut, and this sign is probably a reliable indication of a raised venous pressure. In a few infants violent bleeding was noticed, although pressure was not measured, and these cases have also entered in Table III.

6	Cord	12.2-15.4	0
	1st day	13.7-16.9	

* Normal V.P. +3 to +5 cm. † Treated by exchange transfusion

Deaths

Out of 74 cases there were five stillbirths, 10 deaths within the first 24 hours of life, and seven deaths between the second and fifth days of life. There were only two deaths later than this: one infant (Oa.), who was not seen before the third day of life and was treated by simple transfusion of Rh-negative blood, developed signs of kernicterus on the fourth day and eventually died, in a fit, at the age of 4 months; and one infant who recovered from haemolytic disease but developed congenital pyloric stenosis and died after operation. Of the remaining 50 survivors, only one has any signs suggestive of C.N.S. damage.

TABLE IV.—*Analysis of Fatal Cases*

TABLE IV the time of death is recorded together with the haemoglobin and the first-day venous haemoglobin (when available). It is evident that there is a correlation between low haemoglobin and death on the first day of life. More than half of the seven infants dying between the second and fifth day of life had haemoglobin values well below the normal range a few hours after birth; one (Hi.) had a value just below the normal range and one (Da.) had a value just within the normal range; however, in this latter infant cord blood had

also been tested and found to be anaemic. In the seventh case the haemoglobin value was not determined before transfusion.

Discussion

It has already been mentioned that no infant with a cord haemoglobin value of over 14 g. % died, whereas of 10 infants with values under 8 g. % there were only two survivors. In the intermediate zone there were two deaths among six cases. The idea that the cord haemoglobin is a reliable index of severity receives further support from the observation that seven infants whose cord haemoglobin was within the normal range and who were left untreated pursued a benign course.

Data obtained from the infants first tested some hours after birth lend further support to the theory that initial anaemia is closely correlated with an unfavourable prognosis, since all four deaths in this group occurred in infants whose venous haemoglobin value a few hours after birth was below 12 g. %.

It has long been accepted that infants with hydropic foetalis have a severe anaemia at birth, and it might be suggested that our observations simply restate this fact. It is true that two of the infants whose cord blood was tested were frankly hydropic and others had varying mild degrees of oedema. However, these cases merged imperceptibly into the group who lived on beyond the first 24 hours only to die on the second, third, or fourth day of life; in most of these latter cases it was possible to establish by post-mortem examination that the infant had the changes of kernicterus.

It seems that two distinct mechanisms are operating, and it is to some extent coincidental that the degree of anaemia is correlated with both. It appears that very severe anaemia kills the infant by causing cardiac failure; doubtless the mechanism is similar in many respects to that of the hyperkinetic phase described by Howarth and Sharpey-Schafer (1947) in adults with severe anaemia. The process of birth presumably throws an additional strain on the infant's cardiovascular system and precipitates failure; doubtless also the transfer of placental blood, when it is allowed to occur, may add too great a load.

With regard to the deaths occurring two to five days after birth, two facts seem to be established. First, as Vaughan (1946) and Parsons (1947) have stressed, the deaths are not directly due to anaemia, since many of the infants have haemoglobin values within the normal range at the time of death; it is probable, as Hawksley and Lightwood (1934) first suggested, that the immediate cause of death in these cases is medullary failure consequent upon cerebral damage. On the other hand, these deaths are associated with a certain degree of anaemia at birth, as our observations make clear. The most likely explanation of this association is that the incidence of kernicterus is closely related to the severity of the haemolytic process.

If it is true that the severity of the haemolytic process not only determines the likelihood of the infant's dying from anaemia *in utero* or within 24 hours of birth but also largely determines the possibility of the infant developing kernicterus two to five days later, should it survive so long, other signs of rapid blood destruction besides anaemia should always be present in fatal cases of the disease.

The two most obvious signs to consider are erythroblastaemia and hyperbilirubinaemia. It has often been stated that erythroblastaemia is a variable sign in haemolytic disease, and in the present series of cases it was found in only 33 out of 49 infants examined on the first day of life. However, all of the 16 infants without erythroblastaemia were mildly affected, whereas among the 33 cases

showing erythroblastæmia there were none so mild as not to require treatment. Moreover, these 33 cases included 15 who died within the first five days of life, and in all of these erythroblastæmia was pronounced.

Raised bilirubin values must be interpreted more cautiously, since it is known that the newborn infant has a lowered capacity for excreting bilirubin, and this capacity varies widely from one infant to another; moreover, actual damage to the liver may occur in haemolytic disease (Hawksley and Lightwood, 1934). However, our observation of a moderate correlation between low haemoglobin and high bilirubin values suggests that in fact the hyperbilirubinaemia in infants with haemolytic disease is at least partly due to blood destruction.

The cord bilirubin value, taken alone, does not seem to be quite as satisfactory a criterion of severity as the cord haemoglobin, because only a narrow zone divides mild from severe cases. Not enough data are available to decide whether the haemoglobin and bilirubin values of cord blood, considered together, give a better estimate of severity than either value considered alone, but it is probable that they will prove to do so.

It appears that there is some connexion between the strength of the direct Coombs reaction and the severity of the haemolytic process, since in this series the weakest reactions were found in mildly affected infants. On the other hand, moderately strong reactions were not necessarily associated with signs of rapid blood destruction. One infant who never became jaundiced and developed only a very mild anaemia had a positive direct Coombs reaction for 60 days after birth.

The amount of free antibody in the infant's serum appears to be poorly correlated with severity, since some cases with only traces of free antibody were severely affected and others with moderate amounts of free antibody were mildly affected. At the same time it must be noted that the two infants with the largest amounts of free antibody were both severely affected.

It is evident that there is some correlation between the kind of antibody, and its titre, in the mother's serum and the severity of the disease in the infant, but that the correlation is low, so that exceptions are frequent. In this series the predominance of saline agglutinins over albumin agglutinins in the mother's serum was on the whole associated with milder forms of the disease.

When albumin agglutinins predominated in a serum their titre bore some relation to severity, for there were no very severe cases occurring with very low maternal titres, and deaths were significantly more frequent when the mother's titre was high. Similar conclusions have been reached by Davidsohn and Stern (1948).

Wiener (1946) suggested that the presence of saline agglutinins in the mother's serum caused a disease syndrome "erythroblastosis" associated with deep jaundice and kernicterus; this syndrome was said to come on after birth, since the agglutinins crossed the placenta only during labour and were then thought to cause agglutinative thrombi in the liver and brain; the presence of "blocking" antibodies was said to lead to a different syndrome—"congenital haemolytic disease," associated with anaemia and/or hydrops.

Wiener and Gordon (1948) now consider that saline agglutinins play only a minor part in haemolytic disease, though Wiener (1948) still believes that saline agglutinins may enter the infant's circulation "through placental defects or during labour."

A more convincing hypothesis is that saline agglutinins play no part in the aetiology of haemolytic disease and that sera which contain saline agglutinins can be regarded

as containing in addition a smaller amount of albumin agglutinins. This hypothesis would satisfactorily explain the milder effects of saline agglutinins and is also consistent with the evidence that the haemolytic process is already maximal at the moment of birth.

The idea that haemolytic disease "comes on" after birth has arisen from the fact that jaundice and pallor may be absent at birth but develop rapidly afterwards. However, it is well known that the plasma bilirubin rises rapidly after birth in normal infants, chiefly because of the poor excretory capacity of the liver in the newborn. Therefore a rapid rise in bilirubin after birth does not indicate that the rate of blood destruction is increasing. Our observations demonstrate that even in very mildly affected infants the plasma bilirubin is usually already raised at the moment of birth, and in severely affected infants is always far above the normal range.

A decline in haemoglobin value during the days following birth is also a phenomenon of all normal infants and has been shown to be due to a diminution in the production of erythrocytes after birth (Faxen, 1937; Shapiro and Bassen, 1941). It is very probable that the rapid fall in haemoglobin values during the first few days of life observed in many infants with haemolytic disease of the newborn is also due to a diminished production of erythrocytes rather than to any increase in the rate of destruction. In one severe case reported by Mollison (1943) the rate of destruction of Rh-positive erythrocytes in an infant with "icterus gravis" was measured on the fourth and seventh days of life and found to be distinctly slower on the second occasion. It is common knowledge that in infants with haemolytic disease the degree of erythroblastæmia diminishes rapidly after birth, and it is surprising that so much stress has been laid on blood destruction as a cause of the anaemia, to the complete exclusion of any consideration of changes in the amount of production.

It has been suggested that there is an inverse relationship between the degree of blood destruction and the development of kernicterus (Vaughan, 1946; Parsons 1947). It seems to us that this belief has arisen as follows.

Infants whose cord haemoglobin value is below 8 g.%, usually die within 24 hours of birth and therefore do not have time to develop kernicterus. Infants with cord haemoglobin values of, say, 10–12 g.% may acquire values of 12–15 g.% in venous samples taken a few hours after birth, and capillary samples may show values as high as 18 g.%. The infant's rapid production of cells does not fall off for two to three days after birth, and therefore an infant whose haemoglobin value was 12 g.% at the moment of birth may die on the third day of life with a haemoglobin value of, say, 16 g.%. The fallacy lies in regarding such a haemoglobin value as being necessarily normal. 16 g.% does lie within the normal range of haemoglobin values for the third day of life, but it is normal only for an infant receiving little or no placental blood. In an infant which has received a large amount of placental blood 16 g.% in a capillary sample taken on the third day of life is indicative of anaemia.

Summary

The haemoglobin value in the cord blood of an infant with haemolytic disease is well correlated with the severity of the disease. Infants whose cord blood contains less than 8 g.% are very likely to die within 24 hours of birth. These infants often show a raised venous pressure and probably die from cardiac failure. Infants with values over 14.5 g.% are very likely to recover without treatment. Deaths from kernicterus at two to five days occur in some of those infants who are anaemic at birth but not so anaemic as to die within 24 hours.

Haemoglobin values of blood samples taken after birth are much more difficult to interpret because of (a) the placental

transfer of blood, and (b) the large capillary/venous differences in the newborn.

The cord plasma bilirubin taken alone is a less valuable index of severity than the cord haemoglobin. However, taken in conjunction with the cord haemoglobin it is of definite value in assessing the severity.

In this series erythroblastæmia was present on the first day in all moderately severe cases and was a striking feature in the fatal cases; in mild cases the number of nucleated red cells was usually within normal limits.

The strength of the direct Coombs test and the amount of free Rh antibody in the infant's circulation are of very limited value in assessing severity.

The form of Rh antibody predominating in the mother's serum and the antibody titre show some correlation with the severity of the haemolytic process in the infant. In practice exceptions are frequent, and antibody tests can be used only to forecast probabilities.

These findings emphasize the importance of determining the haemoglobin and bilirubin values of cord blood as a means of grading cases of haemolytic disease of the newborn. Not only is this of help in deciding whether treatment is needed, but it should make it possible to compare one treated series with another and to decide whether equal numbers of severe cases have been included.

We should like to thank the members of the medical and nursing staffs of the Obstetrics Department of this hospital, who have helped in many ways, particularly in the collection of cord blood samples; and Professor A. A. Moncrieff and Drs. D. de la C. MacCarthy, R. Gordon, and R. J. Pugh, of the Department of Child Health, who have had clinical charge of the cases we have investigated.

The British Council for Rehabilitation, which was founded four years ago, has issued the first number of a quarterly magazine (price 2s.) entitled *Rehabilitation*. It publishes a lecture by Sir Hugh Griffiths surveying the field and describing the aims and methods of rehabilitation. "Rehabilitation is treatment," he says, "but it is not the treatment of a disease or an injury but the treatment of the individual suffering from the disease or injury"; and Dr. Edward Dunlop, discussing rehabilitation in Canada, makes the point in another way—"Each disabled person has his own rehabilitation problems, varying in extent and character." The journal is intended for medical men and ancillary workers as well as managers of industry and patients. It is obtainable from the British Council for Rehabilitation, 32, Shaftesbury Avenue, London, W.1.

CHEMOPROPHYLLAXIS OF EXPERIMENTAL FILARIASIS IN THE COTTON-RAT

BY

W. E. KERSHAW, M.B., D.T.M.&H.

Lecturer in Medical Parasitology, Department of Entomology and Parasitology

J. WILLIAMSON, M.Sc.

May and Baker Research Fellow, Warrington Yorke Department of Chemotherapy

AND

D. S. BERTRAM, B.Sc., Ph.D.

Lecturer in Entomology, Department of Entomology and Parasitology

(From the Liverpool School of Tropical Medicine)

It is well known that the blood-sucking mite *Liponyssu bacoti* is a vector of *Litomosoides carinii*, a filarial parasite of the cotton-rat, and that the infection is used in this country and elsewhere for testing the filaricidal activity of drugs. The earlier investigations were made on wild cotton rats which were found naturally infected in the field. A caution is necessary in the interpretation of the results of such experiments (Kershaw and Bertram, 1948), the more recent chemotherapeutic trials have been made on infections of known duration artificially induced in the laboratory.

This may be done by exposing rats to infection by placing them for a few days in an artificial rat-nest containing a colony of mites previously maintained on an infected rat. In our experience and that of other workers successful infection of a rat by this method cannot be predicted with any confidence. One of us (D. S. B.), in studies on the role of the mite as a vector, has found that it is much more efficient than was suggested by earlier work. Infection rates of over 80% have been obtained for infective forms in batches of mites, and, although a mite usually contains only a few worms, instances of about 20 or 30, or in one case even 67, infective worms in a single mite have been observed. This range of variation in the number of worms per mite in mites of the same batch tends to be wide and irregular. The selection of a suitable host for the provision of such highly infective mites will be dealt with in a later communication elsewhere. Using batches of these highly infective mites we have been able to eliminate some of the unknown or uncontrollable factors arising from the use of rat-nests by exposing rats to infection by releasing small numbers of the mites (about 20) on each rat for about 24 hours.

In a series of 41 untreated cotton-rats exposed to controlled infection in this way, 35 out of 37 of those rats from which gorged mites were recovered subsequently showed microfilariae in the peripheral blood, but four rats from which no gorged mites were recovered remained negative. Thus about 95% successful infection was obtained provided there was evidence of the mites having gorged on the rat. On the other hand, these results suggest that unless the mites feed freely on the rat infection does not occur.

We have shown elsewhere (Bertram, 1947) that the mite does not transmit all their worms at the first infective blood meal. Consequently, any estimation of the number of worms transmitted to a rat necessitates dissections of a series of mites before, and of engorged mites after, the transmission meal. Since the number of worms per mite is so variable such estimates are likely to show

considerable deviation from the actual intensity of infection obtained, and in 10 rats for which estimates were made such discrepancies were found to occur. Nevertheless, these dissections are of value since they provide confirmative evidence of transmission having taken place during the act of feeding. Thus in one series the infection rate before the transmission meal was 76%, with a mean of 6.7 worms per mite, and the corresponding figures after the meal were 34% and 1.1 worms.

These observations indicate that, though it is unlikely that the method is suitable for the detection of partial prophylactic action, a drug may be regarded as a complete prophylactic if it prevents the development of infection in a number of animals exposed to infective mites, provided it is known that the infective mites had gorged on the treated animals. With this information at our disposal it has been possible to undertake preliminary experiments to test the prophylactic activity of filaricidal drugs on the following basis.

Basis of the Experiments

Recent work has established the therapeutic efficacy of organic preparations of antimony in filarial infections of man and of cotton-rats. It is not possible to compare the therapeutic activity of the antimonials tested by Culbertson *et al.* (1947a) on cotton-rat infections, but from the experiments on human infections the order of decreasing effectiveness was roughly "neostibosan" (Sb⁺), "urea stibamine" (Sb⁺), "anthiomaline" (lithium antimony-thiomalate) (Sb⁺), "solustibosan" (Sb⁺), "fouadin" (stibophen) (Sb⁺), and tartar emetic (Sb⁺).

Of organic preparations of arsenic only the trivalent derivatives appear to have been tested satisfactorily for therapeutic activity. Several of these show pronounced activity—e.g., phenyl arsenoxide, reduced tryparsamide, "halarsol," and neoarsphenamine (Hawking, 1940; Hawking and Sewell, 1948) (microfilariae of *Wuchereria bancrofti* in vitro and adults of *L. carinii* in vivo), the atypical "Melarsen oxide" (*p*-melaminylphenyl arsenoxide) (*W. bancrofti* in man), "mapharside" (Otto and Maren, 1947) (microfilariae of *L. carinii* in vitro), and *p*-arsenosobenzamide dithioglycollate (Otto and Maren, 1947) (adults of *L. carinii* and *D. immitis* in vivo).

A number of metal-free organic preparations of known therapeutic activity in protozoal and bacterial infections—e.g., derivatives of acridine, sulphanilamide, quinoline, and phenanthridine—are relatively or totally inactive as filaricides (Culbertson *et al.*, 1947b; Hawking, 1947), but two new series of metal-free compounds of novel chemotherapeutic type have been recently reported as highly active—namely, (1) cyanine and styryl-dye-type compounds containing a resonating amidinium-ion system (Welch *et al.*, 1947), and (2) derivatives of piperazine, the most active of which is "hetrazan" (1-diethyl-carbamyl-4-methylpiperazine hydrochloride) (Hewitt *et al.*, 1947; Santiago-Stevenson *et al.*, 1947), the most promising filaricide to date. No adequate data appear to be available for the activity or otherwise of suramin ("antrypol"="germanin"="Bayer 205") or of the diamidines.

Compounds which are known to have pronounced prophylactic activity in trypanosome infections are antrypol, a new quinquevalent antimonial drug "MSb" (*p*-melaminylphenyl stibonate), (Friedheim *et al.*, 1947), and, to a less extent, the aromatic diamidines (Fulton, 1944). Antrypol has been shown to owe its prophylactic activity to retention on plasma protein (Dewey and Wormall, 1946), and tissue retention is responsible for the remarkable prophylactic activity of MSb (Friedheim *et al.*, 1947; Rollo *et al.*, in press): a similar mechanism doubtless obtains for the aromatic diamidines. For this reason, and since a number

of quinquevalent antimonials have been shown to exert filaricidal activity, the three compounds chosen for preliminary prophylactic tests on *L. carinii* infections of cotton-rats were (a) antrypol, (b) stilbamidine, and (c) MSb.

Results

The trial of these three drugs was undertaken by administering a single dose in solution into the peritoneal cavity and allowing the condition of the survivors to become stable. The rats were then exposed to the bites of about 20 highly infected mites, and estimations of the probability of their developing an overt infection were made by recording the number of gorged mites recovered and by dissections of samples of the mites before feeding and after recovery. Five groups of eight rats were exposed to mites, each group consisting of two controls which had not received any drugs and three pairs to which had been given MSb, stilbamidine, and antrypol.

The successful transmission of infection can be established by the appearance of microfilariae in the peripheral circulation about 50 days after the exposure to infective mites or by the examination of the animal some two or three months after exposure to determine whether adults have been produced, for it is possible in low-grade infections in which one or two adults have developed to maturity for one sex only to be present and for microfilariae thus to be absent. In this preliminary trial it was decided to allow the infections which might develop to run their natural course in the first three groups, as it was possible for infection to be delayed in appearance if not prevented, for its subsequent evolution to be protracted, or for its intensity to reach a lower level than those in the controls. The results are shown in the following table.

Chemotherapy of Experimental Filariasis

Drug	No. of Rats	Dose (mg. kg.)	Prophylactic Interval (Days)	Infection Developed

* Not expected to develop an infection, as no gorged mites were recovered.

† Died after exposure to mites.

‡ Developed an infection of low intensity. The antimony content of the blood as determined by trypanocidal titre *in vitro* was between that of a control and another animal which had received a smaller dose of drug. It is presumed that some of the drug had escaped into the gut or had been excreted.

§ Failed to develop an infection (infection probability 95% in control rats).
|| Died three weeks later from heat-stroke. Five adult females and one adult male were found.

The rats to which MSb had been given were examined at intervals varying from four months to nine months after exposure to determine whether adults might be present

in the absence of microfilariae in the peripheral circulation, but none was found.

It is evident that after a single dose MSb can act as a prophylactic against the development of filariasis in the cotton-rat by preventing the establishment of adults in the pleural cavity after the exposure of the animal to the infective larval form in the mite, so far as these experiments show, at a minimum dose of 250 mg. per kg. of body weight and with a maximum prophylactic interval of three weeks. Stilbamidine and antrypol are both inactive at doses of 50 mg. and 500 mg. per kg. respectively at shorter intervals.

We are indebted to Dr. E. A. H. Friedheim for supplying the MSb.

INFECTED INTERVERTEBRAL DISK AFTER LUMBAR PUNCTURE

BY

L. L. BROMLEY, M.Ch., F.R.C.S.

J. DONALDSON CRAIG, M.D., M.R.C.P.

AND

A. W. LIPMANN KESSEL, M.B.E., M.C., F.R.C.S.

(From St. Mary's Hospital, London, W.2)

The use of lumbar puncture as a diagnostic and therapeutic measure is so common that any complication which results from it merits attention. In a review of the literature we found reports of 44 cases of injuries to intervertebral disks, clinically and radiologically established, following lumbar puncture. Only two of these, however, were complicated by infection of the disk or adjoining vertebral bodies.

The majority of cases occurred in children on whom lumbar puncture had been performed for meningitis; those in adults followed a spinal analgesic or some procedure such as encephalography. One of the two infective lesions reported, that by Findlay and Kemp (1943), describes osteomyelitis of the second and third lumbar vertebrae, with destruction of the intervening disk, in a 1-month-old child following an unsuccessful attempt at lumbar puncture in the presence of pyogenic skin infection. The second case (James, 1946), that of a 4½-year-old boy, has some features in common with our own. One week after a difficult lumbar puncture he developed a temperature of 104° F. (40° C.) and flattening and rigidity of the lumbar spine. Shortly afterwards a radiograph showed loss of L3-L4 disk space and later of L4-L5 space with sclerosis of the adjoining vertebral bodies. The illness was complicated by the

development of chicken-pox, but recovery followed plaster immobilization and penicillin therapy.

The clinical picture in all the reported cases—whether accompanied by infection or not—is remarkably constant. At a varying interval after lumbar puncture low backache occurs, accompanied by rigidity of the lumbar spine and diminution of the normal lumbar lordosis. Radiological examination subsequently reveals some loss of intervertebral joint space and, later, sclerosis of the adjacent cortex of the related vertebral bodies. Frequently lumbar puncture has either been repeated or been accomplished with difficulty.

In addition to the two infective complications already quoted, one case of spinal epidural abscess after lumbar puncture had been reported up to the end of 1945 (Rangell and Glassman, 1945).

Case Report

A girl had an attack of meningococcal meningitis in 1943, at the age of 12 years, for which she was treated first at a fever hospital and then at a general hospital elsewhere. Exact details are not known, but she remembers that at least one lumbar puncture was performed under an analgesic. She made a good recovery from her meningitis, but experienced backache and severe stiffness during convalescence. The backache has been present on and off ever since; it has never been severe, nor has it radiated from the lumbar region.

Two years after her illness she developed a tender mass above the middle of her left groin and was treated by sulphonamides and local heat. The mass persisted and she became ill, being admitted to hospital with an irregular pyrexia. A provisional diagnosis of actinomycosis was made at this time and she was given 5,500,000 units of penicillin. The mass softened centrally and discharged pus from which, however, no streptothrix filaments were isolated. After a further course of 7,500,000 units of penicillin the skin over the sinus healed and she was discharged in good general condition.

In October, 1947, she was admitted to St. Mary's Hospital for the first time with a recurrence of the swelling above the left groin. There had been no exacerbation or alteration in the intensity or character of her backache. A radiograph of the pelvis showed no abnormality. Examination under an anaesthetic revealed no palpable intra-abdominal mass. The swelling was subsequently explored and a specimen of tissue sent for histological examination. This revealed chronic inflammatory changes only, and showed that the deep part had not been completely excised. The wound healed, however, and the patient was discharged.

She was readmitted in January, 1948, because a sinus had formed at the site of the operation. Culture yielded *Staphylococcus aureus*. Lipiodol injection and x-ray examination of the sinus showed a track 16 cm. long going across the midline to just above the right anterior-superior iliac spine. A lateral radiograph revealed that the sinus lay in the anterior abdominal wall. No connexion with bone or viscus could be demonstrated.

It was decided to explore the sinus track, and this was done by Mr. A. E. Porritt on Feb. 11. The track lay in its proximal 8 cm. entirely superficial to the aponeurosis and, immediately to the right of the midline, passed deeply, lying on the anterior aspect of the rectus muscle and then between the aponeurosis of the external and internal oblique muscles. It was traced to just above the anterior-superior spine, where no further extension could be found. The wound was then closed, and it healed by first intention.

Further radiological examination was carried out by Dr. T. Richard Riley, who reported on the lumbar spine as follows (see Fig.):

"There is a mild scoliosis convex to the right. The body of L3 shows evidence of irregular bone destruction on its lower surface. The affected margins are sclerosed and there is no sign of present activity. The upper surface of the body of L4 shows irregular shallow bone destruction and appearances otherwise as in L3. The intervertebral disk space between L3 and L4 is still present, but considerably reduced in depth. Comment:

The appearance of the contiguous surfaces of the bodies of L3 and L4 and that of the intervening disk space is consistent with an old localized infective process at this level. The appearance is not that of tuberculous infection. The retention of some degree of disk space, the absence of paravertebral shadow, and the limited involvement of the upper surface of the body of L4 are not consistent with tuberculous destruction. I would say that the appearances are consistent with a pyogenic infection secondary to lumbar puncture."

Radiograph showing antero-posterior view of lumbar spine.

The patient was put into a plaster jacket and discharged in good condition on March 1. When seen in May, 1948, she was in excellent health and had been comfortable and free from backache in her jacket. The operation wound had remained healed and there was no evidence of any recurrence of the abscess. Her E.S.R. at this time was 3 mm. per hour (Westergren). She

was fitted with a lumbar support to be worn in the daytime only.

Discussion

The manner in which the infection in this case presented is interesting. No doubt intensive sulphonamide and penicillin therapy altered the course of the infection, but this cannot explain how an L3-L4 intervertebral abscess tracking laterally round the right side of the abdominal wall should present itself in the left mid-lateral line 5 cm. above the inguinal ligament. At first thought it is tempting to postulate that the pus followed the course of the anterior primary ramus of a lumbar nerve or of a lumbar branch of the abdominal aorta, but simple anatomical considerations show this to be unlikely.

In the majority of reported cases, as in this one, there was no history of sciatic or other root pain, or any related deep segmental pain, in spite of the obvious intervertebral joint disorder. A more detailed study of these patients may throw some added light on the mechanism of pain in intervertebral disk injuries.

The fact that the majority of reported cases have been in children could be accounted for because of the greater frequency of meningitis in children. It is, however, likely that, overall, at least as many lumbar punctures are performed on adults as on children, and the relative frequency of complications among children is therefore probably significant. The danger of intervertebral disk damage is clearly related to the fact that in children the depth of the disk from the skin is much less than in adults, which therefore allows for a smaller margin of error. The annulus fibrosus in young children is no more than 2-3 mm. in depth, and is considerably stretched and thinned in acute flexion of the spine, the standard position for lumbar puncture. Further, the nucleus pulposus is known to be under considerable tension, bulging backwards in acute flexion, and this makes for its easy escape along the needle puncture or its infection by the same means.

Consideration of all these factors might help to minimize the danger of intervertebral disk damage following lumbar puncture, particularly in children.

We are indebted to Mr. A. E. Porritt, under whose care this patient was admitted, for permission to publish this report, and to Mr. V. H. Ellis for helpful advice.

COUGH FRACTURE OF RIBS

BY

RAYMOND C. COHEN, M.D., D.P.H.

Deputy Medical Superintendent and Physician to Pulmonary Tuberculosis Unit, Black Notley Hospital; Tuberculosis Officer, N.E. Metropolitan Regional Hospital Board

The purpose of this paper is to call attention to an infrequent but possibly often unrecognized cause of pain in the chest of sudden onset and resembling dry pleurisy in its symptoms. I have observed a number of cases of "spontaneous" fracture of ribs occurring in tuberculous subjects, in some of which there was a clear history of pain following violent expiratory effort as in coughing or sneezing. These cases happen to have been discovered in women aged between 18 and 35, but other authors have recorded it occasionally also in men.

This condition, which I will describe as cough fracture of ribs, is not widely recognized, and the literature on the subject is scanty.

Halliwell (1929) reported fracture of the sixth, seventh, and eighth ribs after a bout of coughing in a doctor aged 40, of good physique and convalescent from pleurisy and "pseudo-asthma." About a month later, on getting out of a bus, he had another attack of coughing, and x-ray examination revealed a fracture of the ninth rib on the same side as before and in line with the other three. Recovery was uneventful. Howson (1934) was able to trace, in all, 58 reported cases, and added a further case of his own. This occurred in a woman of 26 with bilateral pulmonary tuberculosis who had had a thoracoplasty on the left side, and several months later was found to have a recent fracture of the ninth right rib, older fractures of the tenth and eleventh right ribs, and a fracture of the left tenth rib "with considerable callus formation." Sakka (1938) also described three cases of spontaneous rib fracture occurring in North African natives which he thought were due to tuberculous osteitis. The subjects were all men between 24 and 27, two of whom were suffering from pulmonary tuberculosis. Cramer (1943) described four cases—three in women aged 26, 65, and 72, and one in a man of 72. He thought the fractures were due to muscular action on areas of rarefaction in the ribs, and suggested that the upper five ribs are unlikely to fracture from cough because they are shorter and are supported posteriorly by the scapular musculature.

Case Reports

Case 1.—A woman aged 23 was admitted to Black Notley Hospital on April 8, 1937, for tuberculosis of the left lower lobe. X-ray examination on admission revealed, in addition to the tuberculous disease, a recent fracture of the seventh left rib about 1½ in. (3.75 cm.) from its junction with the costal

FIG 1.—Case 2. Dec. 30, 1937. Oblique film. Fibrocaceous tuberculosis of right upper lobe; recent fracture tenth left rib.

cartilage. The patient gave no history of trauma or sudden pain, but confessed to having had some pain in that area shortly before admission. She had had cough and sputum for about three months.

Case 2—A woman aged 28 was admitted on Oct. 14, 1937, for sluggishly active tuberculous disease of her right sub-apex with a small cavity. On Dec. 30 she complained of soreness in her left side, which she first felt during a bout of coughing. Physical examination revealed a small bump palpable on the angle of the tenth rib, and x-ray examination revealed a fractured rib in that position (Fig. 1). Subsequent films showed callus formation which had almost completely absorbed by June, 1938.

Case 3—A woman aged 22 was admitted on Feb. 18, 1938, for fibrocaceous tuberculosis of her right upper lobe with cavitation. A radiograph on admission showed recent fractures of the anterior ends of her seventh and eighth left ribs, $1\frac{1}{2}$ in. from the costo-chondral junctions. She had not complained of pain at that site, and there was no history of trauma.

FIG 2.—Case 4. Sept. 26, 1941. Right artificial pneumothorax, with small effusion; fracture with callus formation.

Case 4—A woman aged 18 was admitted on April 26, 1938, with acute exudative tuberculosis of the right lung with cavitation. Right artificial pneumothorax was induced on May 2 and adhesions were cut on Nov. 9. She was discharged quiescent on May 7, 1939, and thence attended as an out-patient for refills. A routine x-ray examination on Sept. 26, 1941, showed a fracture of the seventh right rib about 2 in. (5 cm.) from the corresponding transverse process, with some callus formation (Fig. 2). The patient gave no history of pain or trauma.

Case 5—This patient, aged 19, was admitted on Dec. 1, 1939, for exudative tuberculosis with cavitation of her right middle and lower lobes. A radiograph on Dec. 5 showed a fracture with early callus formation of the anterior end of her ninth right rib, about 1 in. (2.5 cm.) from the costo-chondral junction. There were no symptoms at the time of discovery, but on inquiry the patient recalled an acute pain which she had felt low down in her right chest, after a sneeze, a few days before admission.

Case 6—A woman aged 33 was admitted on March 8, 1948, for fibrocaceous tuberculosis of the left lung with upper-lobe cavitation. A radiograph showed old nearly healed fractures of the fifth, sixth, and seventh ribs on the right side, about 4, $3\frac{1}{2}$, and 3 in. (10, 8.75, and 7.5 cm.) respectively from the

FIG 3.—Case 6. April 6, 1948. Bilateral tuberculosis of acute exudative type, with cavitation left apex and right sub-apex; fractures with callus formation of fifth, sixth, and seventh right ribs

costo-chondral junction, so that the fractures appeared vertically above each other (Fig. 3). In November, 1947, she had felt a sudden pain in the right side of her chest, much worse on coughing and catching her breath. She found relief by pressing her hand to her side. The pain lasted about two weeks, gradually diminishing.

Case 7—A woman aged 35 was transferred to Black Notley Hospital from another sanatorium on March 31, 1948, for fibrotic tuberculosis of her left lung. A radiograph on April 2 showed a fracture of the anterior end of her sixth left rib, 1 in. from the costo-chondral junction. Reference to her previous radiographs showed that the fracture first appeared on an x-ray film dated Feb. 13, 1948—it was not seen on the preceding film of Dec. 3, 1947. About Dec. 20 she had felt a sudden pain in the lower part of her left chest which "caught her breath" and was diagnosed as pleurisy. Her chest was strapped for seven days and the pain eased off after a day or two. There was no history of trauma, and she did not think the pain followed coughing, but could not remember for certain.

Discussion

These cases, together with those already reported by other writers, show clearly that it is possible for ribs to fracture as a result of otherwise normal respiratory exercise. The occurrence must be a rare one, but is likely to be observed occasionally by those who see a sufficient number of chest radiographs, and it probably occurs more often than might be supposed. Cases are easily missed if chest radiographs are not carefully examined and the condition borne in mind.

The mechanism of such fractures is difficult to determine. Primary tuberculous osteitis of ribs is generally believed to be so uncommon that it is unlikely to be the basic cause. There was no evidence of it in my own cases, though it is conceivable that areas of bone rarefaction may occur in a rib adjacent to a cold abscess arising from a caseous tuberculous gland; and, so far as I have been able to ascertain, most reported cases, excluding those due to gross localized changes such as secondary malignant deposits or osteitis fibrosa, have occurred in tuberculous subjects, but the condition is not confined to them. Cough fractures of ribs have also been known to occur in elderly subjects, probably associated with increased fragility of bones associated with advancing age, and it would not be surprising if it occurred also, for example, in cases of rheumatoid arthritis, in which rarefaction of bones is sometimes found.

The apparently high incidence in tuberculous subjects suggests a possible constitutional effect on bone structure, but it must also be remembered that such subjects are repeatedly having their chests x-rayed and the lesion is therefore more likely to be discovered.

I have been unable to find any evidence to suggest that the ribs of a tuberculous patient are particularly liable to decalcification, except in so far that prolonged bed-rest may lead to some degree of this from diminished use. Certainly the blood calcium level remains remarkably constant in tuberculous subjects. Healing of the fractures has followed normally, and there does not appear to be any delay in callus formation and eventual union.

The most reasonable explanation of these fractures seems to be the violent and abnormal action, probably associated with asymmetrical posture producing uneven action on the ribs, occurring during the violent expiratory effort of a cough or sneeze. Diminished use of the thoracic musculature that occurs in a patient confined to bed for long periods may also lead to a mild degree of decalcification and be a contributory factor.

The Mental Survey Committee of the Scottish Council for Research in Education has recently completed an investigation into the intelligence of Scottish children. The results were briefly described in *The Times* of Nov. 17, 1948, by Professor Godfrey Thomson, the chairman of the committee. The full results are to be published in a series of volumes, the first of which will appear in the spring. The main task of the investigators was to repeat a group intelligence test given in 1932 to 87,498 Scottish children whose eleventh birthday fell in that year. The same test was given to 70,805 children whose eleventh birthday fell in 1947, but on this occasion much additional sociological information was collected about each child. The possible score was 76 points, and in 1947 the mean score, 36.7, was higher than the mean score, 34.5, in 1932. The boys went up 1.3 and the girls no less than 3.2 points. At least as a first deduction this appears to show that no decline in intelligence is going on, but Professor Thomson thinks the rise may be due to the fact that children are now much more familiar with intelligence tests. The now common observation that intelligent children are more frequently found in small families than in large ones is confirmed. The average score obtained by the only children, 7,824 out of 70,805, was 42 points, and children of families of two averaged nearly as much. But for families of four the average score was 35.3 and for those of eight 28.8.

COUGH FRACTURE IN LATE PREGNANCY

BY

J. W. PAULLEY, M.D., M.R.C.P.

First Assistant, Professorial Medical Unit, Middlesex Hospital

D. H. LEES, F.R.C.S.Ed., M.R.C.O.G.

AND

A. C. PEARSON, M.B., B.S.

Obstetric and Gynaecological Registrar, Middlesex Hospital

Rib fractures due to cough alone, or with an added factor of shearing stress from simultaneous action of other muscles, have been recognized for many years (Gurlt, 1862; Tunis, 1890; Hawley, 1890; Skyrme, 1890; Bähr, 1894). In addition, sneezing, choking, vomiting, and straining at stool are recorded as causes among other varieties of expiratory effort. Numerous forms of exertion, such as a handspring or mounting a restive horse (Hilton, 1852; Seilin, 1917), have also been blamed, although here again associated grunting expiration through partly closed cords may have been responsible.

In recent years the number of cough fractures reported from sanatoria has tended to overshadow the non-tuberculous cases, which may be more numerous but have less chance of being diagnosed. Oechsli in 1936 found 77 cases of cough fracture in the literature to that time. He indicated that when a routine search was made in chest films the incidence of the condition was high. In his series of approximately 3,000 admissions to Olive View Sanatorium 22 cases with cough fracture were found. At the same time Richardson (1936) at Ray Brook Sanatorium reported 20 cases out of 1,903 tuberculous admissions. Osteoporosis in the late stage of phthisis has often been suspected as predisposing to cough fracture, but evidence that it is the chief cause is as yet unconvincing.

Tunis (1890), analysing 40 such stress injuries from muscular action, noted that more than 25% occurred in patients in whom bone fragility could be excluded as a factor, and Seilin (1917) supported this view. Reports since published do not suggest a different conclusion.

Kleiner (1924), quoting Tunis and bringing the literature up to date, found that of 57 cases (which included 14 by muscular action other than coughing) 28 were left-sided, 17 were right-sided, and the side was unrecorded in the remaining 12. There were more fractures of lower ribs than upper, the site of fracture on 19 occasions being the upper seven ribs and on 36 occasions the eighth, ninth, tenth, and eleventh ribs. (The apparent discrepancy is due to more than one rib being involved in some instances.) Kleiner's analysis was made before the papers on the large series of tuberculous cases had been published. In seven of eight patients with fracture of the eleventh rib reported by Tunis and Seilin this was the only rib affected. Multiple fractures appear to be more frequent when the higher ribs are involved.

The older writers (Tunis, 1890; Bähr, 1894) suggest that the preponderance of left-sided damage pointed to a cushioning action of the liver on the right side. Oechsli found no left-sided prevalence and was therefore sceptical of this theory, but the majority of his fractures were mid-thoracic and above liver level. Richardson in a similar series of tuberculous patients noted that the sixth and seventh ribs in the mid-axilla were the commonest sites.

In the literature there are six reports of this accident in pregnancy. Only one occurred during labour, and that in

a coughing fit (Ahern, 1894). Wahl (1926) remarked on the coincidence that four out of five cases described had occurred at the end of pregnancy; the duration of cyesis in the other was not recorded. These cases reported by different authors over many years, together with the four patients in the present series, appear to have features in common: (1) they occur late in pregnancy; (2) they tend to be left-sided; (3) lower ribs are chiefly involved; and (4) multiple fractures are the exception. The details are summarized for convenience in the Table.

Author	Patients' Age and Previous Pregnancies	Duration of Pregnancy	Site of Rib Fracture	Remarks
Hérard (1855) ..	22	7 months	Left 11th	Cough for 6 months
Benoit (Bähr, 1894)	—	In 9th month	Left 9th	Coughing fit (ch bronchitis)

" "	25 primipara	29 "	Left 11th	Coughing after previous choking

Case Reports

Case 1.—Primipara aged 21. 36 weeks. No previous fractures. When seen on Jan. 12, 1947, gave a history for 14 days of sharp pain in the lower left chest posteriorly. A non-productive barking cough had been present for the same length

FIG. 1

of time. Physical signs suggested a small effusion at the left base and chronic bronchitis. X-ray film of chest was negative. Subsequent examination revealed a localized tender lump with crepitation over the tenth rib on the left side. Special views of this area confirmed diagnosis of rib fracture. Control films for bone density showed no osteoporosis. Serum calcium was 9.5 mg. per 100 ml. Serum inorganic phosphate was 3.8 mg. per 100 ml.

Case 2.—Multipara (one previous child) aged 25. 38 weeks. No previous fractures. Seen in antenatal clinic on Jan 7, 1948. In late November, 1947, began to cough and noted slight pain in left lower chest. In mid-December, 1947, three weeks before being seen, while coughing mildly felt a crack

FIG. 2

in same region, with exacerbation of pain. Pain had persisted. On examination, tender over left tenth rib in the posterior axillary line. Radiograph of this area confirmed fracture of this rib and of the ninth. Control films for bone density showed no osteoporosis. Serum calcium was 10.3 mg. per 100 ml. Serum inorganic phosphate was 4.6 mg. per 100 ml.

Case 3.—Multipara (four previous pregnancies, well spaced) aged 36. 40 weeks. Seen Feb. 14, 1948. Gave history of having had a cough for some time. Seven days previously coughing vigorously, and at the same time, when bending and lifting a child aged 3, experienced a sudden pain in the left side of chest and felt something "go." Thereafter unable to cough properly because of pain. Clinically, fracture of eleventh rib left side posterior axillary line with ecchymosis. A.P. radiograph of area confirmed fracture. Comparative control radiographs for decalcification revealed no abnormality. Serum calcium was 8.9 mg. per 100 ml. Serum inorganic phosphate was 4.5 mg. per 100 ml.

Case 4.—Primipara aged 25. 29 weeks. No previous fractures. Seen on Jan. 26, 1948, having had cough for three or four weeks. In early January had had a choking attack and subsequently noticed pain over the left lower chest. Two days before attending had gone out in the evening, and cold air in the street caused her to cough, which was followed by immediate sharp pain in the left side. Radiograph confirmed fracture of eleventh rib. Radiographs for bone density against control revealed slight osteoporosis present. Serum calcium was 10.8 mg. per 100 ml. Serum inorganic phosphate was 4.07 mg. per 100 ml.

A woman in late pregnancy was seen in April, 1946, with what was in retrospect a characteristic history. At the time pleurisy was suspected. A radiograph of the chest was negative and she was dismissed as having had an intercostal muscle tear. It is noteworthy that in her case the lesion was on the right side.

Two other probable cases have been seen, but the considerable administrative difficulties in the immediate antenatal and post-natal periods interfered with the necessary investigations.

The Clinical Picture

If the possibility of the condition is kept in mind a careful history will often give a pointer to the diagnosis. The sudden onset of severe sharp pain during a coughing fit is often supported by a story of something "giving" or "cracking." The four cases described, and the other three possibles, all occurred in the first quarter of the year, when hard unproductive coughs are prevalent and bronchitis are having their winter exacerbations. All the patients were in the last three months of pregnancy.

On examination there may or may not be some fever from the primary chest condition, and the respiration rate may be raised owing to pain on deep breathing. Movement and air entry are diminished at the affected base, and percussion is impaired because of poor aeration or a high diaphragm. Pleural rubs have been noted in some cases of cough fracture. The signs may suggest a small pleural effusion, but it must be stressed that postero-anterior and lateral chest films reveal no abnormality when the lower ribs are involved. If suspicion has not already been aroused it is now that a careful search should be made for a tender localized area on one or more of the ribs. Experience of these pregnancy cases suggests that the left ninth, tenth, or eleventh ribs are the most likely site. Antero-posterior and oblique views will be required to confirm a fracture with minimal displacement in or behind the posterior axillary line.

Discussion

Comparisons of bone density against controls of the same sex and age revealed slight osteoporosis in only one case. Blood calcium and phosphorus estimations were within normal limits. There was no history in any of the cases of previous fractures to suggest pre-existing bone fragility.

If calcium or phosphorus metabolism were a factor in late pregnancy patients one might expect a high incidence in the early puerperium, but so far there is no record of such a case.

If bone fragility can be excluded the remarkable incidence of fracture of lower ribs consistently left-sided and in late pregnancy could be due to a mechanical cause peculiar to the abdominal mass or compensatory lordosis.

It has already been shown that the mid-thoracic fractures occur along the line of interdigitation of the external oblique and serratus anterior (Oechsli, 1936), and are assumed to be the result of shearing stress. The likelihood of fracture is reported to be increased if the serratus is taut at the time of coughing, as it may be when the arm is raised or when the patient is resting on one elbow (Atkinson, 1898; Seilin, 1917; Oechsli, 1936).

In the group of cases in which fracture occurs in the lower ribs a different explanation must be sought. Expiration, normally passive, becomes forced on coughing, but there is some disagreement about which muscles are implicated. Mainland (1945) gives these accessory muscles as: (1) anterior abdominal muscles; (2) latissimus dorsi, but states that its mechanism is not clear; (3) the long back muscles, the lower parts of which are able to depress the ribs.

A study of the anatomy and fracture sites in the majority of pregnancy cases suggests that the shearing stress occurs along the line between the origin of the external oblique (from the lower four ribs) and the costal slips of the latissimus dorsi. This, however, ignores the long back muscles (sacrospinalis). In the pregnant stance the head and shoulders are thrown back; compensatory to this is a lordosis involving increased postural tone, and perhaps hypertrophy of the iliocostalis and longissimus portions of the sacrospinalis. Incoordination or action of more than normal violence might occur in this muscle in such circumstances. Thus forcible expiration, as in coughing with depression of the lower ribs by the iliocostalis, could provide conditions for a shearing stress sufficient to fracture a rib.

Another possible mechanism is that the uterine mass is driven backwards and upwards against the inner surface of the lower chest in coughing by contraction of the anterior abdominal muscles. The main force would be deflected to the left side by the liver on the right. Whether or not the protuberant abdomen is in any way responsible by altering the action or direction of pull of the external oblique must remain at present a matter for further consideration.

Although a fractured rib is a trivial injury it can produce extreme discomfort and insomnia, particularly in a patient who is coughing. That this is undesirable in late pregnancy is self-evident. It would appear from the literature quoted in this paper, and from the present series collected without propaganda in twelve months from two antenatal clinics, that the condition in late pregnancy is not a rarity, and its frequency is probably greater than hitherto appreciated.

The importance of wider recognition lies in the great relief of pain experienced by the patient with early diagnosis and adequate strapping of the chest. Almost equally important is the avoidance of tiresome confinement to bed and needless investigation, often in hospital.

Summary

A brief review of the literature of cough fracture is given, with particular reference to its incidence in late pregnancy.

The clinical picture usually found in this condition is described.

Brief histories of four cases are reported.

Suggestions are made about the mechanism of the condition.

A case is put forward for this rather trivial injury to be regarded more seriously, and a suggestion is made that its frequency may be greater than is generally recognized.

We wish to thank Drs. J. N. Pattinson, F. Pygott, and R. A. H. Kinch for their help, and Miss W. P. Cory and Miss D. Wrighton for secretarial assistance. We are grateful to Mr. J. S. MacVine for access to three of the cases, to Mr. F. Roques for access to the fourth case, and to Professor J. Kirk and Dr. E. W. Walls for advice on the anatomy.

LYMPHOBLASTIC LEUKAEMIA TREATED WITH URETHANE

BY

D. PULLEN, M.B., B.S.

Assistant Pathologist, Royal Alexandra and New Sussex Hospitals, Brighton

The use of urethane in the treatment of lymphatic leukaemia is a fairly recent development, and was first recorded by Paterson *et al.* (1946) in 12 cases of chronic lymphatic leukaemia. Five of these patients were alive at the end of the observation period, but the single case of acute lymphoblastic leukaemia showed no response to treatment.

The following case is noteworthy for the dramatic initial clinical and haematological response to urethane in a child with acute lymphoblastic leukaemia.

Case History

A girl aged 14 months, weighing 24 lb. (10.89 kg.), was admitted to hospital on July 19, 1947, with one week's history of anorexia and fretfulness, associated with vomiting for the previous two days. The mother had recently noticed that the child bruised easily. The past history was one of normal physical and mental development, the diet was normal, and no drugs had been taken. The family history was negative.

On examination the patient was seen to be a well-developed but abnormally quiet child with a very pale, slightly jaundiced skin. Small ecchymoses were present on the limbs, though petechiae were not seen. There was uniform enlargement of the cervical glands, and those of the axillae and groins were easily palpable. The spleen was enlarged to three finger-breadths below the left costal margin and was soft in consistency. The liver could not be felt; the mucous membranes showed neither haemorrhage nor ulceration, and no further abnormalities were detected.

A blood count on July 21 showed: Hb, 42%; white cells, 27,700 per c.mm (polymorphonuclear leucocytes 2%; cells of lymphocytic series 98%). Blood film:—Red cells showed anisocytosis, but were well filled. There was no evidence of red-cell regeneration. The lymphocytic series was made up largely of lymphoblasts, but some degenerating "smudge" cells were also present. The granulocytes were of the early type. Platelets were few. The whole blood picture was highly suggestive of acute lymphoblastic leukaemia.

The count was repeated two days later, when the haemoglobin level had fallen to 28%. The clinical condition had markedly deteriorated, and the child was wretched with buccal ulceration

and was having haematemesis and melaena. The temperature rose intermittently to 102° F. (38.9° C.), and the pulse to 160.

As death appeared imminent from blood loss, 600 ml. of Group O blood was transfused, with marked clinical improvement, on July 23. The same day urethane, 1½ gr. (0.1 g.) thrice daily orally, was started.

The succeeding blood counts are shown in the accompanying Table and Chart. The changes in the blood picture were associ-

Record of Blood Counts

Date	Hb %	W.B.C. per c.mm.	Poly-morphs, %	Metamyelo-cytes, %	Lympho-blasts, %	Lympho-cytes and "Smudge" Cells, %	Mono-cytes, %
21/7/47	42	27,700	2	—	—	98	—
23/7/47	28	5,500	4	0.5	12	83.5	—
1/8/47	58	11,900	37	—	2.5	58.5	2
13/8/47	66	5,700	60	0.5	2	32	5.5
22/8/47	60	4,000	61	—	—	35	4
1/9/47	110	5,400	42	—	—	57	1
9/9/47	102	5,200	67.5	—	—	30	2.5
23/9/47	100	18,150	76.5	2.5	—	18	3

ated with slow but definite clinical changes from a moribund condition to that of a child behaving normally for its age. She was now apyrexial, and although the cervical lymph glands could still be palpated they were considerably smaller. On Aug. 22 the leucocyte count had fallen to 4,000 per c.mm., with 61% polymorphs. Urethane was discontinued, a total of 51 gr. (3.25 g.) having been given over 34 days. A further transfusion of 600 ml. of Group O blood was given to combat leucopenia.

The apparent recovery of the child called for a reconsideration of the diagnosis. A Paul-Bunnell test for glandular fever proved negative. When sent home on Sept. 28 the child appeared to be quite well.

Unfortunately she was not seen as an out-patient because she lived 50 miles away, but in a reply to a letter her private doctor stated that "she went downhill rapidly and died on Oct. 27."

Discussion

Watkins (1947) states that in acute leukaemia of children little or no benefit is obtained from urethane, and that there is not sufficient change to warrant its use other than experimentally. Undoubtedly in this case blood transfusion was a life-saving measure at first, but the dramatic clinical and haematological improvement was far greater than could have been due to transfusion alone. Spontaneous remissions are not uncommon after transfusion in acute leukaemia of children, but a remission rarely lasts more than a week, and the disease is usually fatal within two months of the onset. In the present case the improvement after transfusion was maintained, and would appear to have been enhanced and prolonged by urethane treatment.

The prognosis was exceedingly grave in view of the child's age and of the fall in haemoglobin level to 28%. Paterson *et al.* (1946) attach importance to the initial haemoglobin level, for in three out of four of their cases of lymphatic leukaemia in which the haemoglobin was below 55% the patient died despite adequate blood transfusions.

It is unfortunate that no blood count was done when the final deterioration began, as it is now impossible to say whether this was due to an exacerbation of the original disease or to the toxic effect of urethane on the myeloid cells. This was foreshadowed in the blood count of Sept. 23, when of 18,150 white cells 2.5% were metamyelocytes and 76.5% were young band forms of polymorphonuclear leucocytes.

The use of urethane in this case profoundly modified the disease process, and therefore seems to have been justified.

Summary

A case is described of acute lymphoblastic leukaemia which responded initially to urethane therapy.

The palliative effect in this case would seem to justify further trials of urethane in acute leukaemia.

It is uncertain whether the fatal outcome in the case described was due to the disease or to the toxic effect of urethane on cells of the myeloid series.

Whilst it is probable that the large volume of blood given to this child contributed largely to the remission in the leukaemic state, it seems reasonable to suppose that the duration of this remission was related to the use of the drug.

My thanks are due to Dr. E. D. Scott and Dr. M. A. Leslie-Smith for permission to publish the case, and to Dr. S. Instone for his encouragement and advice.

Medical Memoranda

Malignant Tumour of the Small Intestine

Malignant tumours of the small intestine are relatively uncommon, although reports on more than 500 cases are now available. Carcinoma is said to occur more often than sarcoma in the proportion of 6 to 4 (Mayo, 1940), carcinoma being found most commonly in the jejunum and sarcoma in the ileum. The age incidence in carcinoma is accepted to be higher than in sarcoma, and the sex incidence is in favour of males in the ratio of 2 to 1.

The following report of a case of adenocarcinoma of the ileum differs from those recorded by Rankin and Mayo (1930) in that no loss of weight occurred and no occult blood was found.

CASE REPORT

A publican aged 59 was admitted on Jan. 6, 1948, complaining of generalized abdominal pain and vomiting. His symptoms first began 11 months previously, and consisted of griping pains and vomiting in attacks lasting 10 to 14 days. He suffered some half-dozen such attacks, with intervals of about a month's freedom, before consulting his doctor. Two days before admission he developed generalized abdominal pain with vomiting and for the first time he had absolute constipation.

During the 1914-18 war he contracted malaria and sandfly fever while serving in Palestine. Since that time he had always had two or three loose motions daily, but at no time did he notice blood or mucus in the stools. He suffered for many years from winter bronchitis.

On examination he was seen to be a well-built man with no obvious loss of weight. He was in considerable pain and was vomiting a fairly frequent intervals. The abdomen showed a generalized distension, with some diffuse tenderness on palpation, but no mass was felt. He had shifting dullness in the flanks, and loud borborygmi were heard. Rectal examination showed no abnormality. He was given an enema, which produced a faecal result in the form of a foul-smelling, pale, toothpaste-like ribbon. A further enema on the hour later was returned unchanged, and a diagnosis of intestinal obstruction was made, the cause of which was not obvious.

Operation.—The abdomen was opened through a lower right para median incision and a quantity of straw-coloured fluid escaped from the peritoneal cavity. There was marked distension of the small intestine down to a point 30 in. (76 cm.) from the ileo-caecal valve

A hard mass about the size of a tangerine orange involved the gut at this point and occluded the lumen of the bowel. A resection of 8 in. (20 cm.) of the bowel including the tumour, together with a wedge of mesentery containing enlarged glands, was carried out, continuity being restored by lateral anastomosis. The anastomosis was performed first, as the patient's condition had deteriorated, but as it subsequently improved resection became possible. The abdomen was closed and the patient returned to bed with an intravenous glucose-saline drip and a gastric aspiration in operation.

Pathology of the Tumour-bearing Intestine.—"The loop of small intestine is involved by a stenosing carcinoma of scirrhus appearance. The tumour is about 1 in. (2.5 cm.) in length and encircles the whole wall. No gross ulceration of the mucosa is observed and no polypi are seen. Careful search fails to reveal any associated lymph glands involved by metastases. Histological examination showed an adenocarcinoma which is deeply infiltrating the bowel wall, with an accompanying scirrhus reaction. The lesion is not of carcinoid origin, the tumour consisting of acini of varying size, showing irregularity in cell type and nuclear configuration."

Convalescence was lengthened by a post-operative pneumonia but was otherwise uneventful, and the patient was discharged on Jan. 23. When last seen two months later he was well and leading a normal life.

I am indebted to Mr. G. F. Mitchell, under whose care the patient was admitted, for permission to publish this case, and to Dr. R. L. Bishton and Dr. R. C. Hill for the pathological report on the specimen.

A Case of Inherited Spina Bifida

The aetiology of foetal deformity is still uncertain. Such diverse factors as heredity, multiparity, diabetes, placenta praevia, and maternal rubella have variously been incriminated. The inheritance of minor deformities along Mendelian lines is not uncommon; while the occurrence of a major deformity in siblings increases the chance of such deformity reappearing, though Gibberd (1947) considers this to be only a fourfold increase above the normal probability. Direct inheritance of major deformity from the mother is naturally uncommon, and the following example is worthy of record.

CASE HISTORY

A primigravida aged 21, in her 37th week of gestation, was admitted to hospital on May 7, 1947, with diagnosis of toxæmia and disproportion. The toxæmia proved to be minimal, but examination disclosed a fluctuant swelling the size of a coconut in the midline of the lumbar region, extending from the second lumbar to the first sacral vertebra. There was exaggeration of the lumbar lordosis, but no scoliosis; the swelling was compressible and had a well-marked cough impulse. Both feet showed pes cavus (right more than left). There was wasting of the thigh and calf muscles on the right, and $\frac{1}{2}$ in. (1.9 cm.) shortening of the right lower extremity. A diagnosis was made of meningocele, and the spinal deformity was confirmed by radiography at a later date.

Obstetrically, the case was one of brim disproportion, with a floating head and some slight degree of hydramnios. X-ray examinations were intended, but labour started spontaneously the night after admission, and vaginal examination soon showed that the disproportion was caused by a hydrocephalic head; this was perforated at half dilatation of the cervix, and a female foetus weighing 6 lb. 1 oz. (2.75 kg.) was delivered uneventfully. It showed a moderate hydrocephalus, with a gross dorsi-lumbar spina bifida of the open myelocoele type.

COMMENT

No reference to the inheritance of spina bifida has been found in the available literature, and Ford (1946) does not include it in an exhaustive list of inherited disorders. Despite the difference in degree of the foetal and maternal condition it seems reasonable to suppose that some genetic factor had been transmitted and that further pregnancies would run a very considerable risk of being similarly affected. It is impossible to assess the relative importance of heredity and environment in relation to the developmental errors of the young embryo; the majority of gross abnormalities are lost as abortions, while of those which are born alive only a very small percentage reach reproductive life and have the opportunity of passing on to the next generation whatever genetic

factor may be involved. There is a growing tendency to find environmental factors such as dietetic deficiency (Warkany, 1944), rhesus iso-immunization (Wiener, 1946), and maternal rubella (Gregg, 1941) to account for foetal deformity, but it seems probable that many cases of gross defect are genetic in origin.

My thanks are due to Mr. Samuel Davidson for permission to publish this note.

Occurrence of Convulsions During Treatment with Calciferol

The value of high dosage of calciferol in the treatment of lupus is well established, and in view of the success of the method its use is likely to be further extended until the therapeutic effect has been evaluated in other tuberculous infections. Calciferol has been recognized as a potentially toxic drug, and anorexia, nausea, vomiting, and polyuria are well known to follow its use. So far, however, I have seen no record of the occurrence of convulsions after calciferol and therefore consider that the following case should be put on record.

CASE HISTORY

A boy aged 10 was admitted to the Surrey County Hospital with a history of malaise for one month and an unexplained pyrexia of one week's duration. On admission the temperature was 101° F. (38.3° C.). The abdomen was full and slight tenderness was present on deep palpation in the R.I.F. No definite mass was felt, but on bimanual examination with a finger in the rectum a large gland was discovered low in the right side of the abdomen. White cells numbered 7,500 per c.mm. (P. 70%, L. 20%, M. 9%, E. 1%). The Mantoux test was positive 1 in 10,000. X-ray examination of the chest revealed nothing abnormal. A diagnosis of tuberculous mesenteric adenitis was made, and treatment with calciferol 50,000 units twice daily was started. The temperature settled rapidly, with an occasional evening rise to 99° F. (37.2° C.). On Nov. 21, 1947, the boy was allowed home at his parents' request, to rest in bed and continue calciferol, 50,000 units twice daily. There had been no symptoms of intolerance during his stay in hospital, but the parents were warned of the possible occurrence of toxic symptoms. On Dec. 15 he was readmitted to hospital suffering from generalized convulsions. It appeared that, in addition to the 100,000 units of calciferol prescribed, an ampoule of sterogyl containing 600,000 units had been given by mouth a week previously. Soon afterwards nausea, occasional vomiting, and obstinate constipation had developed; he became increasingly drowsy and could not be roused for some hours before the first convulsion began.

On admission very frequent generalized convulsions were occurring; no focal signs were present on examination of the central nervous system except for an extensor plantar response on the right side, which became flexor 48 hours later. Treatment included 0.25 g. of soluble hexobarbitone intravenously, followed by $\frac{1}{2}$ gr. (0.1 g.) of soluble phenobarbitone intramuscularly two hours later. Apart from a further slight convulsion and slight vomiting recovery was uninterrupted, being complete in 48 hours. The blood calcium was 18 mg. per 100 ml. on the day of admission, falling to 14.8 on Dec. 22 and 12.9 on Dec. 29. The urinary output was well maintained and the urine contained no albumin or casts. The blood urea was not estimated.

There was no family history of fits, nor had the boy suffered previously from convulsions.

COMMENT

In view of the fact that increasing concentrations of calcium are known to decrease the frequency of impulses discharged from nerve cells stimulated with acetylcholine it seems likely that the fits were due to a direct toxic effect of calciferol rather than to the associated hypercalcaemia. Overdosage with calciferol is known to produce a rise in the blood urea, but in the absence of oliguria or albuminuria it seems unlikely that the convulsions were uraemic in origin.

HEWARD BELL, M.B., M.R.C.P.

Reviews

GENITO-URINARY SURGERY

Textbook of Genito-Urinary Surgery. Edited by H. P. Winsbury-White, M.B., Ch.B., F.R.C.S., F.R.C.S.Ed. With 39 Eminent Contributors. (Pp. 1046; 451 illustrations, many in full colour. £4 10s.) Edinburgh: E. and S. Livingstone. 1948.

There can be no doubt of the importance of this book. It is the first work written by many authors that has come from the British school of genito-urinary surgery, and as such it is sure of a welcome. To edit such a book is no light undertaking, and any criticisms of this impressive volume are made with a full realization of the arduous work that its production must have entailed for Mr. Winsbury-White.

One of his many difficulties must have been to select the contributors, of which there are thirty-nine. A skilful surgeon is not necessarily a clear exponent of his art, and even if he can write he may be tempted to give undue prominence to the methods of treatment he favours and to the particular technique he uses in operating, thus giving an unbalanced account of the subject he discusses. It is risks of this kind that an editor in command of so large a team must take. Inevitably the various contributions to this work are of unequal value, and it would be invidious to try to compare the quality of the different sections. All that can be said is that the editor has chosen contributors that are good representatives of British genito-urinary surgery, although one or two names we might have expected to see are missing. It would have been more convenient if the names of the various writers had appeared at the beginning of their articles instead of being tucked away at the end of them. So also might it have been preferable if such a bulky and heavy tome as this had been broken into two volumes, but the shortage of boards and the scarcity of binders may well have made this difficult. The illustrations and the coloured plates are of a very high order. The need for an up-to-date work by British urologists has long been apparent, and we confidently expect that this handsome volume will find a place on the bookshelves of a great many surgeons, not only here in England but abroad.

MEDICAL RESEARCH IN AMERICA

American Medical Research Past and Present. By Richard H. Shryock, Ph.D. Studies of the New York Academy of Medicine Committee on Medicine and the Changing Order. (Pp. 350 14s.) New York: The Commonwealth Fund. London: Geoffrey Cumberlege. 1947.

This book is something new and exciting in medical literature. The author is a non-medical professional historian. It is essentially a social history of medical research which relates the development of medical research in the U.S.A. to the economic progress of society. There have been four phases in American medicine: the British influence from 1750 to 1820, the French from 1820 to 1860, the German from 1860 to 1895, and the independent American tradition thereafter. Until the end of the nineteenth century the mainspring of American life was commerce and the pursuit of wealth, and none of the disinterested arts—painting, music, or medical research—really flourished there. The turning points were the growing realization of the importance of science to national life and industrial prosperity, the foundation of the Johns Hopkins Hospital, which set a new pattern for medical education in America, and the Rockefeller bequests, which directly and indirectly stimulated the expansion of medical research.

Dr. Shryock discusses with dispassionate understanding many problems that still beset us—the difficulty of securing adequate rewards for teaching and research in a competitive society, the arguments for and against security for the research worker, the difficulties of team work, the problems of planning research in a free society. There are signs that in America also the era of private support for research is coming to an end owing to the diminishing number of large incomes under individual control. The State is becoming more and more the dominant partner in subsidizing research. It has been estimated that,

whereas just before 1940 total expenditure on all forms of scientific research in the U.S.A. was about \$250,000,000, of which only \$50,000,000 were Federal funds, by 1944 more than \$600,000,000 was being spent by the Federal Government alone. It has even been suggested that research should be established as a fourth branch of government. These developments have given rise to the usual fears of the regimentation of science, and the usual controversy for and against planning of work and on the relative importance of fundamental and applied science. Dr. Shryock's book is therefore more than a history of American medical research: it is a discussion of the basis and philosophy of research in general. It is clearly written and closely documented, and will be of the greatest value to all who benefit from, take part in, or make provision for medical research.

L. J. WITTS.

LECTURES ON PSYCHO-ANALYSIS

Lectures on Psychoanalytic Psychiatry. By A. A. Brill, Ph.B., M.D. (Pp. 259. 15s.) London: John Lehmann. 1948.

This book can be recommended without reservation. Unlike so many publications purporting to describe psycho-analysis, it is an authoritative work written by the acknowledged founder, and mainstay of psycho-analysis in the U.S.A., who until the day of his death practised and taught Freudian analysis with unswerving devotion to its principles. It consists of a series of lectures given annually to audiences of young psychiatrists for close on a quarter of a century. Based on a ripe experience of both psycho-analysis and psychiatry, and written in a clear and almost racy style, it can be read with understanding by any intelligent layman wanting to acquire some orientation in both subjects.

Of particular interest to the general reader is the introductory chapter, in which Brill describes the state of psychiatry when, shortly after his qualification, he made his first approach to the subject. The descriptive psychiatry of Kraepelin, which, thanks to the exertions of Meyer, was then much in vogue, soon left Brill dissatisfied, and a journey to Paris in search of more effective therapeutic methods was equally disappointing. At this point, Brill tells us, he nearly threw up the sponge; but a lucky recommendation to visit Burghölzli, where Bleuler together with Jung and others were investigating the theories of Freud some twelve years after they were first adumbrated, led to his complete conversion to the psycho-analytical approach. Incidentally, his asides on Jung's belligerent and irascible devotion to Freud are particularly intriguing in the light of Jung's later repudiation of Freud and all his works, or at any rate his abandonment of all that mattered in psycho-analysis. In these days, when newcomers to psychiatry are inclined to take for granted that the discoveries of Freud were just an important part of a general psychiatric progress, it is well to be reminded so uncompromisingly that Freud was the founder not only of psycho-analysis but of modern clinical psychology.

EDWARD GLOVER.

EARLY MEDICINE IN INDIA

The Beginnings of Modern Medicine in Madras. By D. V. S. Reddy. With foreword by Major-General J. B. Huban, Surgeon-General with the Government of Madras. (Pp. 240. 5 rupees.) Calcutta: Thacker, Spink and Co. (1933), Ltd. 1947.

Dr. Reddy's book is an interesting and very readable addition to the history of medicine in the Madras Presidency from the early days of the ship surgeons of the East India Company to the dawn of modern medicine there—the foundation of the Madras Medical School in 1835, the precursor of the present institutions, hospitals, colleges, and laboratories in the Presidency. The author dedicates his book to his teachers in the Madras Medical College and associated teaching hospitals, and in the opening words of his preface he says that this work, based on the study of original records, is the outcome of his love and gratitude to his alma mater, the Madras Medical College, and its parent institution, the Madras General Hospital—institutions that have trained thousands of medical men and saved the lives and health of millions of mankind, men, women, and children, of all nationalities and creeds. Nor in the reviewer's opinion is his claim exaggerated, for at the Madras

General Hospital there is probably a greater wealth of available medical material relating to tropical medicine than at any hospital in the world and an atmosphere as democratic is that in any large London hospital. One reason is that Madras has a longer history of close association with the West than any other part of India; it is almost the only part of that sub-continent where a large European, Eurasian, and native Christian community has long been naturally domiciled. The result has been that modern medicine has had a very favourable soil in which to develop.

In a prologue the author describes very briefly the general evolution of medicine, outlining its sources from Graeco-Roman, Arab, Ancient Indian, and Western European systems; he fixes the date for the beginning of modern medicine as barely 300 years ago. When the first ships from Europe touched the West Coast of India towards the close of the fifteenth century India was, as the author points out, neither a vast dark continent like Africa nor devoid of medical practitioners, as the edicts of Asoka and other records show. Nevertheless, modern medicine came from the West. Beginning with an account of the medical arrangements of the East India Company, he describes its history in those early days during which medical organization and technical advance passed by slow stages and often through troublous times to what blossomed forth into the modern medical institutions that now serve the needs of fifty millions of multitudinous race, creed, and social status.

RICKARD CHRISTOPHERS.

GUIDE FOR STUDENTS

The Clinical Apprentice. A Guide for Students of Medicine. By John M. Naish, M.D., M.R.C.P., and John Apley, M.D., M.R.C.P. With foreword by Professor J. A. Ryle. (Pp. 200; 71 illustrations. 15s.) Bristol: John Wright and Sons. 1948.

This book is one of the best and one of the shortest of the many which undertake to guide the footsteps of the student newly entered upon his clinical career. The approach throughout is clinical in the strictest etymological sense, and the patient, instead of being disarticulated into a collection of unrelated systems, is allowed the privilege of remaining an indivisible whole. The authors have omitted any discussion of clinical pathology and the arid pages of anatomy and physiology which encumber so many books of this type. In simple, almost colloquial language, with a leaven of equally simple humour, they introduce the student to his first patient and explain the basic principles of physical examination. This lively and unpretentious little book provides the clinical clerk with just what he needs during his first few weeks in the medical wards without arousing despondency by revealing too clearly how much he has to learn.

R. BODLEY SCOTT.

The Hospitals Year-Book 1948 (British Hospitals Association, 52, Green Street, W.1; £1 1s.) is mainly a directory assembling a mass of useful information about the regional hospital boards, the grouping of hospitals under management committees, and the designated teaching hospitals under boards of governors. The list of hospitals disclaimed from the National Health Service by the Minister of Health is given. There are 256 of these, the majority being small or of a denominational character. The *Year-Book* also sets out the hospitals as they were on July 4, 1948. The statistical tables of the work and finances of the voluntary hospitals before the taking-over are now a closed chapter, but they have their interest. In particular it is shown what a tremendous financial burden the steeply rising costs became. The cost of the voluntary hospitals for maintenance alone rose by 115% between 1938 and 1946. However, there was a large increase in voluntary contributions under the shadow of impending change. The increase in cost was not confined to voluntary hospitals: municipal and mental hospitals show comparable increases. The editor, Mr. J. P. Wetenhall, suggests that the risk of remote control by no means yet a thing of the past, although the position has been considerably safeguarded by the final form of the Act and by certain subsequent regulations which imposed a considerable measure of responsibility on the new hospital management committees. It is clear from this compilation that there is a great public interest in hospitals and a desire on the part of many to do personal service. A constitution for Leagues of Friends, through which active interest and support for local hospitals may be rallied and maintained, has been drawn up by the British Hospitals Association.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Die Weiblichen Sexualhormone in der Pharmakotherapie. By O. Mühlbock and others. (Pp. 300. 24.80 Swiss francs.) Berne: Hans Huber. 1948.

The chemistry, pharmacology, and therapeutic uses of the female sex hormones.

Höhenklima-Forschungen des Basler Physiologischen Institutes. Edited by F. Verzar. 2nd ed. (Pp. 97. No price.) Basle: Benno Schwabe. 1948.

Papers on physiological changes at high altitudes.

Les Facteurs Vasculaires et Endocriniens de L'Affectivité. By A. M. P. Abely and others. (Pp. 190. 400 francs.) Paris: L'Expansion Scientifique Française. 1948.

A study of the physiological changes that may accompany affective disorders.

Schicksalsanalyse. By L. Szondi. 2nd ed. (Pp. 422. 28.50 francs.) Basle: Benno Schwabe. 1948.

Analysis of the individual's destiny in relation to his mental inheritance and family environment.

Heredity in Essential Hypertension and Nephrosclerosis. By P. Søbye. Vol. 16. (Pp. 225. No price.) Copenhagen: Arnold Busck. 1948.

The author concludes that the development of these disorders is probably always due to a hereditary gene.

Hungerkrankheit, Hungerödem, Hungertuberkulose. By A. Hottinger and others. (Pp. 297. 28 francs.) Basle: Benno Schwabe. 1948.

The pathological and clinical effects of starvation and its consequences.

Gadd's Synopsis of the British Pharmacopoeia. By H. W. Gadd. 15th ed. (Pp. 249. 5s.) London: Baillière, Tindall and Cox. 1948.

A summary of the 1948 B.P., with notes on the law relating to poisons and dangerous drugs.

A.M.A. Interns' Manual. Issued by the American Medical Association. (Pp. 201. 12s.) London: W. B. Saunders. 1948.

Notes on laboratory tests and on the uses and prescription of the commoner drugs.

Health Teaching in Schools. By R. E. Grout, M.P.H., Ph.D. (Pp. 320. 20s.) London: W. B. Saunders. 1948.

A manual for school teachers.

Clinical Studies of Besnier's Prurigo. By P.-H. Nexmand. (Pp. 236. No price.) Copenhagen: Rosenkilde and Bagger. 1948.

A monograph on the disorder, with special reference to its treatment.

The Principles and Practice of Rectal Surgery. By W. B. Gabriel, M.S., F.R.C.S. 4th ed. (Pp. 508. 45s.) London: H. K. Lewis. 1948.

The text has been revised and a new chapter on anal incontinence included.

Dictionary of Genetics. By R. L. Knight, D.Sc., Ph.D., A.I.C.T.A. (Pp. 183. \$4.50.) Waltham: Chronica Botanica. 1948.

Includes terms used in cytology and animal breeding.

Morals in the Melting Pot. By E. F. Griffith, M.R.C.S., L.R.C.P. (Pp. 295. 9s. 6d.) London: Methuen. 1948.

The author discusses such topics as contraception, divorce, extra-marital relationships, homosexuality, and preparation for marriage.

Human Physiology. By C. G. Douglas, C.M.G., M.C., D.M., F.R.S., and the late J. G. Priestley, M.C., D.M. 3rd ed. (Pp. 258. 18s.) London: Geoffrey Cumberlege. 1948.

A practical course for the student of physiology.

The Narrow House. By H. Fernée. (Pp. 272. 8s. 6d.) London: Christophers. 1948.

A thriller set in Soho.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 22 1949

HAEMOLYTIC DISEASE OF THE NEWBORN

Haemolytic disease of the newborn continues to be the subject of intensive research, and advances in knowledge of two kinds have been published recently. In the first place the predictions of Fisher have been confirmed by the discovery by independent observers of both anti-d serum¹ and the Cde (Rh₀) type.² It is therefore probable that the boundaries of the Rh antigen-antibody scheme are now fully revealed, though within those boundaries Race and his co-workers have displayed in the elementary antigens C, c, D, and probably also E a complexity of antigenic structure at first unsuspected. In spite of lack of agreement on the terminology to be employed, whether the Rh-Hr or the CDE/cde system is the better, it is accepted on both sides of the Atlantic that the Rh group is of complex structure built up from a number of alternative components each of which may on occasion prove antigenic in those from whose constitution it is absent. Lack of agreement on nomenclature does not conceal the essential agreement on the facts now accepted by all workers in this field, who, whatever symbols they may use, realize that they are working with the same components.

The second type of advance is well exemplified by the authoritative paper by Dr. P. L. Mollison and Miss Marie Cutbush published in this issue of the *Journal*. While the fundamental cause of haemolytic disease of the newborn lies in the iso-immunization of the mother against a blood-group antigen which she herself lacks, Rh incompatibility being by far the most common cause, there has been a great deal of uncertainty about the exact mechanisms concerned and about when and how to treat the affected infants. Mollison and his co-workers have done more than anyone to fill in some of these gaps in our knowledge and understanding. The present publication supplements their earlier work on exchange transfusion³ and on physiological jaundice of the newborn,⁴ and provides for the first time easily accessible criteria of severity which every obstetrical unit should be able to determine. A group of 52 normal infants served as controls for 74 affected infants born to immunized Rh-negative mothers. Sixty-nine of the latter group were live-born, and of these 50 were seen on the day of birth. The tests included examination of the blood for haemoglobin and bilirubin content, and the direct Coombs test for sensitization of the red cells. In 41 of the affected infants the serum was also tested for free Rh antibodies, and in 62 the maternal serum was titrated for both saline-agglutinating and albumin-agglutinating antibodies.

Perhaps the most important observations made by Mollison and Cutbush are those on the prognostic value of haemoglobin estimations in the newborn and their significance in determining the line of treatment required. They

confirm the substantial rise in haemoglobin levels a few hours after birth brought about by reflux of blood from the placenta and show that anaemia in the newborn can thereby be concealed; capillary blood samples invariably gave higher readings than cord or post-natal venous blood. In normal infants the haemoglobin or cord blood has values of 14–19.4 g. per 100 ml., the mean value being 16.35 g.; within 24 hours the mean value rises to 18.45 g. if placental reflux has been permitted. Of 30 affected infants 14 had cord-blood values within the normal range, and none of these died; 16 had lowered values, and it is noteworthy that only two out of eight infants with less than 8 g.% of haemoglobin survived. When venous blood was examined a few hours later two infants with subnormal values in the cord blood were found to have values within the normal range of infants not recovering placental blood and this increase was even greater in capillary blood. It is therefore clear that assessment of anaemia in the newborn is much more accurately made on cord-blood samples than on post-natal venous or capillary blood. If only the latter are examined the extent of the haemolytic process may be underestimated and decisions about treatment might be adversely influenced. Some correlation also exists between the degree of anaemia and erythroblast aemia; infants with less than 10 nucleated red cells per 100 white cells had usually over 12 g.% of haemoglobin, and all of these recovered. On the other hand, 11 infants died among 33 whose nucleated red cells numbered more than 20 per 100 leucocytes; primitive forms were abundant, and in all except one the haemoglobin was below 12 g.%.

Another important criterion of severity is the bilirubin content of the blood. In normal infants the values lie between 0.8 and 2.6 mg.% (average 1.6 mg.%), whereas in affected infants the cord-blood bilirubin is raised, indicating that increased haemolysis has been going on *in utero*. Cappell⁵ drew attention to the pronounced yellow colour of the umbilical cord in affected children, an observation which may first attract the obstetrician's attention to the disease in the absence of generalized icterus. The level of cord-blood bilirubin has some prognostic significance, for six out of 11 infants with more than 4 mg.% died. In mildly affected infants left untreated, whose cord bilirubin values ranged from 1 to 3.7 mg., the amount in the venous blood rose between the second and fifth days of life to 1.3–15.8 mg. Obviously, therefore, blood bilirubin level is of prognostic importance only if the estimation is made on cord-blood samples.

In earlier studies Mollison⁴ brought forward evidence that the rate of destruction of erythrocytes does not increase after birth, being normally about twice as rapid in the first 10 days of life as at later ages. Physiological jaundice of the newborn is therefore largely due to functional inadequacy of the liver, and anaemia in the neonatal period as Faxan⁶ and Shapiro and Bassen⁷ showed, is largely due to insufficient replacement of the destroyed cells. In haemolytic disease the rate of blood destruction is maximal at birth, and the rapid onset of symptoms is due to the physiological stresses attendant upon the establishment of a separate existence.

Wiener⁸ claimed that the type of foetal disease could be accurately predicted from the nature of the maternal antibodies, Rh saline agglutinins being associated with icterus gravis, erythroblastosis, and kernicterus, whereas Rh albumin agglutinins were found in cases of hydrops and congenital anaemia. These views found little or no favour with other workers, but Wiener⁹ has recently modified them so that he now attaches little or no clinical importance to the presence of Rh saline agglutinins alone in the maternal serum and attributes all forms of haemolytic disease to the presence of antibodies of the albumin-agglutinating type, which he prefers to call univalent antibodies or glutinins. Wiener suggests that only univalent antibodies are capable of traversing the placenta, and he claims that their titre in the maternal blood is closely correlated with the severity of the resulting foetal disease: when the foetus is Rh-negative, and therefore unaffected, the univalent Rh antibody titres of maternal and cord serum are equal, but when the foetus is Rh-positive the foetal red cells become coated by adsorption of the antibodies, the titre in the foetal serum being thereby reduced. Wiener applies this concept also to cases of sensitization to A or B, holding that these are due to the development of immune univalent anti-A or anti-B; he explains the absence of haemolytic disease in most heterospecific pregnancies by failure of the normal isoagglutinins α and β to pass through the placenta in sufficient amount to cause harm.

Mollison and Cutbush, on the other hand, are less satisfied that there is any close correlation between the maternal antibody titre and the prognosis for the foetus. They agree that a high titre of albumin-agglutinin is usually associated with severe anaemia and is a bad prognostic sign, but the converse is not true and many exceptions are encountered. Cases with predominantly saline agglutinins are usually less severely affected, and none of these infants died within the first 24 hours. They stress the impossibility of separating cases sharply into the three main varieties of hydrops, icterus gravis, and congenital anaemia, and consider that these merge imperceptibly the one into the other. Their experience of titrating the Rh antibodies in the infant's serum is also rather different from Wiener's,¹⁰ and they found the amount of free antibody very poorly correlated with the severity of the haemolytic process—one infant with a titre of 1:16 was so mildly affected as to require no treatment, though the cells gave a positive direct Coombs test, while others died within 24 hours in spite of a very low titre. On the whole they favour the view that albumin agglutinins are all-important in the aetiology of the disease, since this is more in agreement with their conception of maximum haemolysis before and at birth rather than with the onset or aggravation of haemolysis after birth. In such a view none of the varieties of haemolytic disease is due to entry of maternal antibodies into the foetal circulation only during labour, nor is it necessary to postulate that the effects of blocking antibodies are increased by "conglutinin" rapidly produced after birth. Wiener's conception of this process is at variance with the morbid anatomy of the disease, as Cappell¹¹ emphasized.

In Mollison and Cutbush's series, out of 69 live births 50 infants survived, and of these only one has shown signs of cerebral damage: whereas in those dying on the second

to the fifth days nuclear jaundice was commonly present. Without doubt this complication greatly diminishes the chance of survival, but, as Parsons¹² has pointed out, this is not to be deplored. Although these infants were anaemic at birth, in some this was no longer apparent at the time of death, and a marked erythroblastæmia was evidence of rapid regeneration of red cells in some cases. Mollison and Cutbush do not accept the idea of damage to the central nervous system by the direct action of Rh antibodies on tissue cells. Their work suggests that the three forms of haemolytic disease are merely manifestations of different degrees of haemolysis. If this has been severe and long-continued before birth the foetus is profoundly anaemic and hydropic and is either stillborn or dies within 24 hours, before there is time for severe jaundice and kernicterus to develop. If the process is less severe the infant may live over the first few days; when the excessive haemolysis and functional immaturity of the liver lead to a accumulation of bilirubin and other waste products formerly excreted through the placenta; damage to the liver may follow, and this in turn may play a part in determining the occurrence of cerebral damage. The mildest cases of all, the congenital anaemias, are those in which jaundice is not severe but anaemia of varying degree develops. The paradox of absence of severe jaundice but with progressive anaemia may be partly explicable by less severe blood destruction than in icterus gravis together with a more efficiently functioning liver, while the anaemia is probably attributable not only to some excess haemolysis but, perhaps even more to an exaggerated depression of haemopoiesis such as Shapero and Bassen⁷ have shown to be concerned in the anaemia of normal infants in the neonatal period. If, therefore, haemolytic disease is due solely to the effects of the albumin agglutinins, it is a little surprising that there is not a better correlation with the titre of such antibodies in the maternal serum, and perhaps there may be some further type of antibody concerned, as Hill, Haberman, and Jones¹³ have suggested.

Mollison and Cutbush have demonstrated clearly the great value of the direct Coombs test, which they found invariably positive in affected infants; furthermore, the strength of the reaction was fairly well correlated with the maternal titre of albumin agglutinins and was to some extent of prognostic significance, in so far as a weakly positive reaction was not found in any severely affected infant. The converse, however, was frequently observed, and it is surprising to learn that the direct Coombs test may remain positive, in infants not treated by exsanguination transfusion, for longer than 93 days. If the trans-placental passage of Rh antibodies is regarded as an example of passive immunization it would appear that when the cells are destroyed the antibody may be dissociated from the antigen in a form which is capable of

function of the thyroid hormone is not clear. It is logical to assume that the increased metabolic rate which results from the administration of thyroid may necessitate an increased intake of the B vitamins. Many of the individual vitamins will give some protection against the loss in weight that occurs in experimental hyperthyroidism, although Betheil and his colleagues¹ at the University of Wisconsin have recently shown that none is as good in this respect as liver, which produces better growth and improves the chances of survival. The antithyrotoxic factor of liver is heat-stable, it is not destroyed by heating with acids or alkalis, and it does not appear to be identical with any of the known B vitamins. Work is in progress at the University of Wisconsin on the fractionation of liver preparations to obtain more information on the properties of this antithyrotoxic factor and to isolate it if possible.

MEAT INSPECTION

Meat inspection in England is far behind what is the practice in many other countries. In a paper read earlier this year at the annual conference of the National Veterinary Medical Association Mr. Horace Thornton¹ made several suggestions for its improvement, but his contention that there had been virtually no change in fifty years will not pass unchallenged. A reduction in the number of slaughter-houses from some 16,000 to under 600 during the war years and the appointment by the Ministry of Food of a team of advisers on meat inspection, mostly veterinary surgeons, have in fact resulted in a noticeable improvement. In England inspection is still done almost entirely by sanitary inspectors holding a special certificate in meat inspection, a system which many people think should give way to one supervised by veterinary surgeons.

Emergency killings—that is to say killings done without prior notice and in unauthorized places—have always caused trouble. Figures from Germany show that three-quarters of the illnesses caused by meat infected with *Salmonella* can be traced to emergency killings, in spite of the fact that there the law requires such carcasses to be detained until they have been examined bacteriologically; in Austria no emergency slaughter is allowed at all. In several countries tuberculous meat is passed after sterilization, but this has never been legalized here, and, though some meat would be saved, it is doubtful if even to-day the British public would look favourably on such a practice. In the past British standards of judgment were severe, and much good meat, when inspected at all, was condemned unnecessarily. But during the war meat inspectors began to show greater discrimination, and there is no reason to believe that they do not still pass as much meat as is possible without risk to the public.

Meat inspection in England could be greatly improved. The Ministry of Health has for over twenty years advocated the ante-mortem inspection of animals awaiting slaughter, but few local authorities have made the necessary veterinary appointments. Ante-mortem inspection reveals many animals which are obviously sick but which may show few physical signs of disease on post-mortem inspection. Such inspection is desirable, but the routine inspection of one carcass after another is dull and monotonous work which few veterinary surgeons would care to undertake even if there were enough of them, and it might be better to appoint trained and experienced men, not necessarily sanitary inspectors, to do the routine work under the general supervision of a veterinary surgeon, as

is the practice in Scotland. But such a change would not be possible unless the Government decided to restrict permanently the number of slaughter-houses. Many of them, too, need to be drastically improved. There is much to be said in favour of combining the supervision of slaughter-house inspection with the control of disease in herds, a function of the Animal Health Division of the Ministry of Agriculture.

THE PRODUCTION OF INSULIN

The demand for insulin continues to increase, since the number of patients who suffer from diabetes mellitus and remain alive grows larger every year and, in addition, patients with schizophrenia are now treated with insulin shock. The sole source of insulin is the pancreas obtained from cattle and fish, and reports received by WHO show that over a ten-year period there may be an annual deficit of 400,000,000 international units if production remains at the same level. In this country fortunately there appears to be no danger of shortage. Mr. J. C. Hanbury,¹ chairman of the British insulin manufacturers, has recently pointed out that "the production of insulin . . . is adequate to meet in full both home and export demands, and ample stocks are always maintained." The position in Germany, however, is not satisfactory, and great efforts have been made to improve the output. In order to obtain the best yield of insulin the pancreas glands should be cooled rapidly to a temperature of -20° to -30° C. This process is impracticable in the small abattoirs in Germany, and Dr. F. Lindner² has introduced a method of chemical dehydration. The fresh pancreas is collected as soon as possible after slaughtering, cleaned, and placed in cold storage at a temperature of $5-8^{\circ}$ C., which is fairly easily achieved. Some time within the next twelve hours the glands (12–15 kg. at a time) are placed on the plate of a butcher's rotary cutting machine and 700 g. of finely ground anhydrous sodium sulphate added for each kilogram of pancreas. The machine is then started and in ten minutes the pancreas has been completely disintegrated and intimately mixed with the sodium sulphate. The mass is spread on iron plates in a layer 5 cm. thick for one hour and then placed in the refrigerator. The next day the slabs are hard and are stored in a refrigerator at $5-8^{\circ}$ C. until needed, but they can be stored at room temperature, up to 30° C. if necessary, without damage. The extraction of the pancreas then proceeds in the usual way. It is stated that the yield is as good as that obtained by the freezing method, but Mr. Hanbury disagrees with this. It seems clear, however, that chemical dehydration will enable insulin to be extracted from pancreas which would otherwise be wasted and that it should help to increase the supplies of insulin in all countries in which the abattoirs have no means of freezing the fresh pancreas. Meanwhile research on the constitution of the insulin molecule continues, and success in this respect would probably soon lead to the synthetic production of insulin. Once this is achieved all anxiety about the supply of insulin should be at an end. It is to be hoped that the efforts of the chemists will soon be crowned with success.

The Milroy Lectures will be delivered by Dr. Marc Daniels, M.R.C.P., before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday and Thursday, Feb. 15 and 17, at 5 p.m. His subject is "Tuberculosis in Post-war Europe."

MODERN LANGUAGES IN THE SERVICE OF MEDICINE

BY

RAYMOND WHITEHEAD, M.D., D.Sc.

(From the Department of Pathology, University of Manchester)

At one time or another the problem of foreign languages presents itself to a large proportion of the medical profession. French and German are among the essential tools of the teacher and research worker, and are of at least temporary concern to the candidate for a higher degree by thesis. Other modern foreign languages are not widely cultivated by British medical men, but those who can read them are valued as translators, reviewers, and abstracters. For these reasons it is of interest to determine how far various languages are used by medical writers and to discuss the problems that the diversity of languages creates for medical libraries, readers, and authors.

Languages of Publications Indexed

Table I shows the publications indexed in the *Quarterly Cumulative Index Medicus* classified according to language.

TABLE I.—Languages of Publications Indexed

	Books			Journals		
	1937	1947	Changes since 1937	1937	1947	Changes since 1937
Czech	1	—	-1	6	4	-2
Danish	2	1	-1	3	3	—
Dutch	4	2	-2	7	10	+3
English	525	584	+59	417	531	+114
French	188	44	-144	197	103	-94
German	264	42	-222	176	41	-135
Hungarian	—	—	—	5	1	-4
Italian	112	122	+10	129	116	-13
Norwegian	—	—	—	2	—	-2
Polish	—	—	—	4	2	-2
Portuguese	6	13	+7	33	71	+38
Rumanian	—	—	—	7	—	-7
Russian	5	7	+2	14	14	—
Spanish	13	56	+43	85	216	+131
Swedish	1	—	-1	1	1	—
Unclassified	13	8	-5	75	44	-31
Total	1,134	879	-255	1,161	1,159	-2

The figures were calculated from lists in the *Quarterly Cumulative Index Medicus* Vols. 21 and 41. The lists relate only to the first six months of each year.

The figures for 1937 show that the leading languages were English, French, German, and Italian; in 1947, on the other hand, they were English, French, Italian, and Spanish.

The figures for other languages for both years raise doubts about the completeness of the *Index*. For example, it is difficult to accept the suggestion of the figures that only a dozen medical books in Russian appear each year or that the medical journals in this language number no more than fourteen. The figures for Swedish—one book and one journal—are likewise almost certainly too low; the catalogue of the Swedish Publishers' Association for 1946 lists sixty-three books and twenty-one journals dealing with medical subjects in the Swedish language. These comments are made not by way of criticism of the indexers, who obviously can deal only with publications accessible to them, but to indicate that a language may be used by medical writers more extensively than the *Index* would suggest.

Three languages show substantial gains since 1937—namely, English, Spanish, and Portuguese. Table II shows the contri-

TABLE II.—Main Sources of Indexed Journals in English, Spanish and Portuguese

	1937	1947	Gains since 1937	
			Actual	Percentage
British Isles	91	95	4	4.4
United States	272	372	100	36.8
Spain	13	27	14	107.7
Spanish America	68	186	118	173.5
Portugal	8	4	-4	-100.0
Brazil	23	66	43	135.7

The figures were calculated from the lists of journals indexed in the *Quarterly Cumulative Index Medicus*, Vols. 21 and 41.

butions of Europe and America to these gains. It also shows that each language gained in both Europe and America, but that the gains by each language were both absolutely and relatively greater in America.

Languages of Journals in a Library

The Manchester Medical Library takes approximately a quarter of the journals indexed; Table III shows (a) the language distribution that would be expected if its list of journals were a miniature replica of the list of journals indexed, and (b) the language distribution observed.

TABLE III.—Languages of Journals in a Library Taking a Quarter of the Journals Indexed

	Expected			Observed		
	1937	1947	Changes since 1937	1937	1947	Changes since 1937
English	104	133	+29	191	253	+62
French	49	26	-23	22	26	+4
German	41	10	-31	46	—	-46
Italian	12	22	+10	2	—	-2
Portuguese	8	18	+10	1	—	-1
Spanish	21	51	+30	1	5	+4
Others	31	20	-11	11	4	-7
Total	289	290	+1	288	288	—

The "expected" figures were found by dividing the figures in Table I by 4, "others" including both the "unclassified" of Table I and languages unspecified in Table I only. The "observed" figures were calculated from lists in the *Annual Report of the Manchester Medical Society* for 1946-1947 and 1947-1948.

In each year the observed figure for English is much higher than the expected; on the other hand, the observed figures for Spanish and Italian are in each year much lower than the expected.

Languages of Articles Abstracted and Books Reviewed

Table IV gives examples of the languages of (a) articles abstracted in *Abstracts of World Medicine*, and (b) books reviewed in the *British Medical Journal*.

TABLE IV.—Languages of Articles Abstracted and Books Reviewed

	Articles	Books		Articles	Books
Czech	1	—	Italian	25	1
Danish	5	—	Swedish	9	—
Dutch	3	—	Polish	2	—
English	816	245	Portuguese	1	—
French	56	22	Russian	11	—
German	44	15	Spanish	10	—
Hebrew	1	—	Swedish	9	—
Hungarian	2	—	Turkish	1	—

The figures relate to the first 1,600 articles abstracted in *Abstracts of World Medicine*, 1937, Vol. 2, and to the 296 books reviewed in the *British Medical Journal* in 1947.

Of the articles abstracted, over four-fifths were in English, and the only foreign languages individually accounting for more than 2% of the total were French, German, and Italian. Of the books reviewed, over four-fifths were in English and the rest of the others were in French or German.

Languages and Library Policy

The importance of various languages varies with the point of view. The most general point of view is perhaps that of a library committee, whose task is to meet the needs of a medical community. One of the main functions of such a committee is the selection of journals; according to the funds and space at its disposal, it has to provide the journals that will be most useful to the readers it serves. Its work may involve making judgments of quality between journals in the same subject, or deciding between the claims of journals in different subjects. General usefulness, as well as quality, must be considered; it would be uneconomic to take a journal, however excellent, if a language that no one could read. The decision not to take a particular journal therefore does not necessarily mean it is of poor quality; on the contrary it may be of high quality but in too small demand to justify a subscription. A decision does not entail hardship for usually borrow the journal from some

direct or through his local library; alternatively he may obtain an individual article in the form of a reprint from the author or of a photostatic or microfilm copy. In reaching decisions a library committee naturally bears in mind these various possibilities.

Comparison of the "expected" and "observed" figures in Table III shows a strong preference for journals in English. This is not surprising, since English is the language most widely read by users of the library. The library serves both practitioners and the university staff. It is known that requests for journals in foreign languages are virtually confined to the university staff, and it is accordingly their judgment that is reflected in the figures for French and German. The insignificant representation of other foreign languages probably means that few if any users of the library read them; it does not mean that the medical literature in these languages is unimportant—evidence to the contrary is provided by a steady demand for translations from them by those using the library. The language from which translations are required most often is probably Italian, and on some topics the literature in this language is substantial; for example, in a study of Still's disease (Langley, 1945) no fewer than 9 out of 30 references are to Italian papers.

Selection of Articles for Abstracting

The abundance of medical literature has led to a demand for summaries or abstracts of medical articles, and there are now, of course, several journals consisting entirely of such abstracts. The reading of abstracts is a convenient means of keeping in touch with developments in medicine, but it must always be remembered that an abstract is a second-hand account, however skilfully rendered. An abstractor has to condense pages into sentences, and must inevitably select for mention the points that he himself thinks important or interesting. As a rule, his selection of points can be made only in the light of his general experience; even if he happens to be an expert on the subject of an article, other experts might dissent from his judgment. Anyone working on a particular topic must consult an article in the original (or in translation) and form his own opinion of its value; all that he needs is a list of titles of articles such as those given in the *Index Medicus*. When all efforts to obtain access to an article have failed it is permissible to quote an abstract in the list of references at the end of a paper; such a quotation can properly be made only for information, for it would not be fair to an author to judge his work on the evidence of an abstract.

Because of their limited value, abstracts are costly. Their cost is to be measured less by the price of abstract journals than by the diversion from other work of the energies of abstractors, who are themselves often engaged in research. The preparation of abstracts is an exacting task and a severe test of critical and literary powers combined; if the text is in a foreign language great care is needed to avoid mistranslations. For these reasons the selection of articles for abstracting is a heavy responsibility, and the aim should be to provide the best possible service with the minimum expenditure of effort. Ideally, articles could be chosen for their quality or interest irrespective of the language in which they are written, but in practice the choice may fall short of the ideal owing to inaccessibility of journals or lack of linguists. The example in Table IV certainly suggests a preference for articles in English, but the best articles may in fact have been in English, in which case it would not necessarily represent a departure from the ideal policy.

Because of the widespread knowledge of English and the ready accessibility of journals in English, it might be suggested that articles in English do not need abstracting, and that abstract journals would be more useful if they confined themselves exclusively to abstracts of articles in foreign languages. Such a policy would undoubtedly have the advantage of disseminating information that would otherwise remain relatively inaccessible, but it is doubtful whether most users of abstracts would be willing to forgo the convenience of having a balanced review of the whole of current medical literature.

Selection of Books for Review

The restriction imposed by general ignorance of foreign languages is more severe for book reviews than for abstracts

and of the same nature as that influencing the selection of journals by a library. The abstractor is free to range widely in the literature in foreign languages, for many of his readers will be content with his abstracts and not read the original articles. The book reviewer, on the other hand, is largely concerned with introducing books to potential readers. Book reviews would therefore be expected to deal mainly with books in the mother tongue, and the range of foreign languages providing books reviewed would be expected to be narrower than for articles abstracted. The data in Table IV are therefore in agreement with expectation.

The Englishman already has access to a large amount of foreign literature in his own language; for English is of course the mother tongue of many foreign countries, the United States being simply first among them. At the same time the close genetic relation between medicine in the British Isles and medicine in the other English-speaking countries gives the medical literature of these countries a special interest for the Englishman, and the books they publish are often of more immediate use to him than those from countries speaking foreign languages. Books in foreign languages—especially textbooks—often reflect practice that differs considerably from that in the English-speaking countries; for this reason they are in general less interesting than books in English, and reviews are accordingly less necessary. There are of course notable exceptions, and it is most desirable that they should be reviewed; in this matter we must look to the enterprise of foreign publishers and foreign cultural representatives in this country in submitting books for examination.

Reviews for journals published in this country should preferably be written by natives of the British Isles, since the value of such reviews largely depends on their being written against the background of our own system of medical education and practice; a review of a foreign book (whether in English or some other language) by one of the author's fellow-countrymen could hardly carry the same weight. The medical profession in this country is large enough to provide reviewers of books in every important European language, and medical men with linguistic ability should be aware of this opportunity of serving their colleagues.

Languages and the Individual Reader

Medical men who have to read articles in foreign languages are mainly specialists, and therefore interested not so much in the total output in any language as in the leading journals in their own subjects. For any individual this probably means one or two journals in each of a considerable number of languages: if he cannot read a language he must have articles translated. The languages most frequently needed are French and German: anyone who has learnt both at school has thus saved himself much time and trouble. On this subject we could hardly improve on the observations of La Bruyère (quoted by Locke, 1692):

"One can scarce burden Children too much with the Knowledge of Languages. They are useful to Men of all Conditions, and they equally open them the Entrance, either to the most profound, or the more easy and entertaining Parts of Learning. If this irksome Study be put off to a little more advanced Age, young Men either have not Resolution enough to apply it out of Choice or Steadiness to carry it on. And if any one has the Gift of Perseverance, it is not without the Inconvenience of spending that Time upon Languages, which is destined to other Uses: And he confines to the Study of Words that Age of his Life that is above it, and requires Things; at least it is the losing the best and beautifullest Season of one's Life. This large Foundation of Languages cannot be well laid but when every thing makes an easy and deep Impression on the Mind; when the Memory is fresh, ready and tenacious; when the Head and Heart are as yet free from Cares, Passions, and Designs; and those on whom the Child depends have Authority enough to keep him close to a long continued Application. I am persuaded that the small number of truly Learned, and the Multitude of superficial Pretenders, is owing to the neglect of this."

French usually presents no problem, for it is commonly learnt at school and can be quickly revised if necessary. German, on the other hand, is less often studied at school and is generally considered to be the more difficult language. German is important owing to the large amount of good work

published in it before the war and will retain its value for years even if there is no revival in German medicine.

Whether any further language should be acquired is a matter for the individual to decide. The learning of French and German, especially if either has to be learnt after leaving school, may well take up all the time that can be spared for language studies, and only those with a special interest in languages are likely to proceed further. Those who do so will find that English and German together smooth the way to the other Germanic languages; Icelandic is highly inflected and at least as difficult as German, but the other important members of this group—Danish, Norwegian, Swedish, and Dutch—are all grammatically simpler than German and among the easiest of foreign languages for the Englishman. French is similarly helpful in the study of Italian, Spanish, Portuguese, and Rumanian, all five being descendants of Latin.

Tables I and IV together show that medical literature is published in fourteen foreign languages other than French and German, and the lists are almost certainly incomplete; the medical linguist thus has a wide choice, and the selection for study of a foreign language other than French and German may rightly be influenced by non-medical interests such as general literature or foreign travel. The medical reader of any foreign language other than French and German will probably attract as much work as he can comfortably cope with, and if he teaches in a university he may expect work from colleagues in any faculty.

Languages from an Author's Standpoint

The language problem for a medical author is relatively simple, for the choice lies between his mother tongue and one or other of the so-called world languages—English, French, and German—if he was not born into one of these. The advantages of writing in one's native language need no discussion, for no one can feel quite so much at home in any other; an Englishman would be the last to question an author's right to publish in his own language if he so desires. On the other hand, the disadvantages—namely, a limited public and the risk of being misunderstood by foreign readers—are equally obvious, and with many writers outweigh the advantages. Such writers vary in their choice of language, which is often determined by the traditional intellectual relations of their countries; thus German is often used by Russians and Japanese, and French by citizens of the other Latin countries. English ensures the widest public, and foremost among those who use it are the Scandinavians. Let us be grateful for their choice and hope that their example may be followed ever more widely.

Summary

Publications listed in the *Quarterly Cumulative Index Medicus* have been classified according to language. In 1937 the leading languages were English, French, German, and Italian; in 1947 they were English, French, Italian, and Spanish. English, Spanish, and Portuguese show substantial gains since 1937; each language gained in both Europe and America, but the gains by each language were both absolutely and relatively greater in America. In 1947 about one-half the indexed journals were in English and about one-fifth in Spanish; no other language accounted for more than one-tenth.

Comparison of indexed publications with (a) journals in a library, (b) articles abstracted, and (c) books reviewed shows a strong preference for journals, articles, and books in English; the implications of this preference are discussed.

The value of French and German, both as keys to medical literature and as aids to the study of other languages, is emphasized. The data show that medical literature is published in at least fourteen foreign languages other than French and German, and it is suggested that the selection for study of foreign languages other than French and German may rightly be influenced by non-medical interests. The advantages of publishing in world languages, especially English, are noted.

I am indebted to Mr. G. Wilson (Librarian) and to Mr. F. C. Hirst (Cataloguer), of the Manchester Medical Library, and to Professor S. L. Baker for their kindness in reading the manuscript.

ORDER OF ST. JOHN OF JERUSALEM

The *London Gazette* has announced the following promotions in, and appointments to, the Venerable Order of the Hospital of St. John of Jerusalem:

As Knight: Dr. C. E. C. Wilson. *As Associate Knights:* Major-General K. S. Master, M.C., K.H.P., and Dr. Jivraj N. Mehta. *As Dame:* Dr. Margaret E. Douglass. *As Commanders (Brothers):* Brigadier R. A. Hepple, C.B.E., M.C., M.B., Colonel C. P. Gaboury, O.B.E., M.D., Major E. S. B. Hamilton, M.C., F.R.C.S., Drs. C. A. Verco and C. Thompson. *As Commander (Sister):* Lady Isabel E. Hutton, C.B.E., M.D. *As Officers (Brothers):* Brigadier F. A. E. Crew, M.D., Colonel M. MacEwan, D.S.O., O.B.E., D.F.C., T.D., M.B., Lieutenant-Colonels D. W. C. Gawne, M.D., F.R.C.S., R.A.M.C., H. F. Summons, M.B.E., M.B., G. N. Morris, F.R.C.S., Majors T. D. W. Fryer, M.B., C. D. Donald, M.B., Captain S. A. Nield-Faulkner, L.R.C.P.S., Drs. I. H. Beattie, R. I. Hyder, G. A. Macdonald, J. T. Whitley, O.B.E., H. R. Mustard, E. W. Lonsdale-White, H. M. Ayres, A. Tabone, and A. W. Azzopardi. *As Associate Officers (Brothers):* Rai Bahadur Captain K. S. Roy, M.B., and Dr. G. S. Vazkar. *As Officer (Sister):* Dr. Dora E. Wheeler. *As Serving Brothers:* Lieutenant-Colonel O. L. Appleton, T.D., L.R.C.P.S., R.A.M.C., Major M. J. Bett, M.D., Captains F. R. Wilson, M.D., R.A.M.C., J. B. W. Meredith, M.B., F. E. Barclay, M.B., Surgeon Captain V. F. Walsh, L.R.C.P.S., R.N., Drs. E. Sorabjee, J. G. Morgan, G. K. Arthur, J. F. E. Burns, W. J. Collins, C. E. Mathieson, D. S. Smith, H. T. H. Dimitriou, R. A. Simpson, R. B. Hick, L. W. Bradshaw, W. S. Coutts, A. W. Ewing, G. E. Sawdon, F. R. Mutch, N. Wilson, T. D. Thorne, H. F. Sparling, M.B.E., J. M. Hain, G. R. Bourne, F. W. Gershaw, H. C. Powell, G. Saine, H. M. S. Tait, A. Parkinson, F. G. Percival, O.B.E., and V. C. F. Tet. *As Associate Serving Brothers:* Drs. E. A. Levisseur and C. K. Khey. *As Serving Sisters:* Drs. Phyllis Burns, Mary E. Rolston, and Ellice E. P. Dart.

Reports of Societies

LONDON COUNTY MEDICAL SOCIETY

Addressing the London County Medical Society at a meeting held at Furnival House, Highgate, on Jan. 5, and presided over by Dr. C. D. Coyle, Mr. J. R. M. WHIGHAM, the retiring president, said that the ideal hospital had yet to be built. Design must have some relation to function, and "job efficiency" had always to be kept in mind. Nowhere in the hospital was this more necessary than in the ward. The subdivided ward, with opportunities for recreation for those able to enjoy it, was an urgent need for the future.

For the doctor hospital medicine was not total medicine, and every opportunity should be taken to fill in the gaps so that the patient could be studied in the light of his family, his house, his job, and his pay. Close contact with the relatives was desirable, and on transference back of the patient the general practitioner should be given a full account of the case.

Though the doctor was not immediately concerned with rising hospital costs he could by careful scrutiny see that the maximum use was made of the beds of which he was in charge. The aged sick who were acutely ill, and those likely to benefit by it, should receive hospital treatment. Others should be kept at home, and no one wanted this more than the elderly patients themselves. Unfortunately some homes were not only not fit to live in, they were not even fit to die in. The hospital had to rescue these unfortunate people. It was not realized, either inside the profession or outside, how numerous were the day-to-day administrative problems in a hospital dealing with all sorts and conditions of patients. The need for "a head" remained, and, a hospital being what it was—a medical service primarily—that head was most naturally a doctor. Medicine to be at its best must flow freely and naturally and not be forced along artificial channels. No two hospitals were alike; each had its own problems, and therefore must be allowed some degree of autonomy.

SCOTTISH SURGICAL PAEDIATRIC CLUB

In view of the increasing number of surgeons whose work is wholly or mainly concerned with infants and children, a Scottish Surgical Paediatric Club has been formed. The first meeting was held in Glasgow and was attended by twenty-seven members, representing Aberdeen, Dundee, Edinburgh, Glasgow, and Inverness. A dinner was held in the Royal Faculty of Physicians and Surgeons on the evening of Dec. 17. On Dec. 18 a very full day was spent at the Royal Hospital for Sick Children, Glasgow. Four short papers were read in the morning, and the afternoon was devoted to clinical and pathological demonstrations. The next meeting will be held in Aberdeen in May.

Preparations and Appliances

ENDOMETRIAL BIOPSY CURETTE

Dr. ERNST FRIEDMANN, Fertility Department, Royal Free Hospital, writes: The importance of endometrial studies in functional sterility and long-standing amenorrhoea has long been recognized. The number of instruments which have been recommended for endometrial biopsies shows that none has really proved satisfactory, whether it be endometrial punch forceps, the intrauterine suction apparatus, the suction cannula with syringe, or models like Sharman's curette, the disadvantage of which seems to be the "dead space" in it.

I have therefore designed a curette which can readily be used on out-patients without danger and with the least discomfort. The total length of this curette is 10½ in. (26.5 cm.). It has a flat handle with a groove at the distal end to allow a comfortable but firm grip. The stem is graduated, is malleable, and terminates in an inverted V-shaped loop, in which are incorporated two cross-bars which play an important part—i.e., retain the specimen. The calibre corresponds to the thickness of an ordinary uterine sound, which in my opinion should always be passed before introducing the curette. The cervix should be steadied with a vulsellum. The curette is then drawn down the upper part of either the anterior or the posterior wall or both with slight pressure only and without undue force. On immersing the curette in the fixing solution the piece comes off readily. Only occasionally have I found it necessary to shake the curette a little.

I have used this curette exclusively since 1946 in 300 biopsies. All but those very few cases in which a uterine sound could not be passed and consequently the curette could not be inserted, the strip of endometrium was such that glands and stroma were not separated or fragmented. It was almost always a single strip which on section included practically the length of the glands with surface epithelium and stroma intact.

The instrument is manufactured by Allen and Hanburys Ltd. in stainless steel, and is available with straight or angled handle.

Edward A. Humphreys, M.D., of Columbus, Ohio, U.S.A., has been appointed President of the American Association on Mental Deficiency. Dr. Humphreys qualified in 1930; after working in the New York Psychiatric Institute and the Fifth Avenue Hospital he was for ten years Director of Research at Leitchworth Village. In 1945 he assumed his present post as Chief of the Bureau of Prevention and Education, Division of Mental Hygiene, Ohio, and has served as Acting Commissioner of Mental Hygiene for over a year.

Correspondence

Significance of Proteins in Nutrition

SIR,—Readers are supposed to serve some sort of useful service by calling attention to errors which they have detected and by making comments which may be of some interest to other readers. I hesitate to make these adverse criticisms of an otherwise excellent paper by Dr. D. P. Cuthbertson (Oct. 23, 1948, p. 731) on the significance of proteins in nutrition and their particular importance during convalescence.

1. The author at one point states, "Satisfactory nutritional preparations will undoubtedly extend the benefits of surgery," and includes in these "high-protein, high-carbohydrate diet fed where necessary by tubal methods"; yet elsewhere the contradictory statement is made, "There is little point in trying to supply the patient with food in excess of that which appetite dictates." It has become abundantly clear to me on the basis of many personal observations that nutritional depletion occurs in many surgical patients because the surgeon fails to combat anorexia. That Dr. Cuthbertson has failed to emphasize this important point is illustrated by a letter in your *Journal* (Nov. 27, 1948, p. 959) from Dr. E. Sakochansky, who quotes the Cuthbertson paper to justify reliance on the patient's appetite, saying, "Much needless anxiety would be removed thereby," and casting aspersions upon the feeling of relatives who "are apt to worry unduly because a sick person does not eat."

2. In deprecating the use of intravenous amino-acid mixtures Dr. Cuthbertson states, "Plasma and glucose are safer fluids," which is a little misleading inasmuch as these two substances can scarcely be compared on the basis of commonly observed potential reactions.

3. Spence, Evans, and Forbes (*Ann. Surg.*, 1946, 124, 131) are quoted as having made a study of a mixture of ten essential amino-acids (including their intravenous use), whereas these workers actually employed oral preparations of whole protein in their surgical cases.

4. Dr. Cuthbertson quotes a paper of mine incorrectly by stating that "90 g. of protein takes 8 to 9 hours in a volume of 2,500 ml." Actually, in my experience with thousands of injections 50 g. of amino-acid mixtures rarely require more than 3 hours, and this is given in a volume of 1,000 ml. Our routine is to give an average-sized adult patient unable to eat two litres per day, one in the morning and one in the afternoon, each requiring between 2 and 3 hours for the intravenous injection. Each litre contains 50 g. of amino-acid mixture and 50 g. of glucose, plus a little over 2 g. of sodium chloride.—I am, etc.,

Saint Louis, Minnesota.

ROBERT ELMAN.

SIR,—Dr. Robert Elman was good enough to send me a copy of his letter (see above), and I should like to consider it paragraph by paragraph.

1. My statement that "satisfactory nutritional preparation will undoubtedly extend the benefits of surgery," including "high-protein, high-carbohydrate diet fed where necessary by tubal methods," refers to pre-operative treatment of depleted patients, when it is desirable to secure as much restitution as possible of body tissue by ingested or infused food material. When I make the statement, "There is little point in trying to supply the patient with food in excess of that which appetite dictates," I am referring to the immediate phase of protein catabolism following injury, when I consider that the body is not, in general, geared to anabolic activity. I had hoped that both these points were made clear in my paper.

2. Dr. Elman will find my most recent views on protein hydrolysates and pure amino-acid mixtures in my paper on "Assessment of Knowledge Concerning the Clinical Use of Protein Hydrolysates and Pure Amino-acid Mixtures" (*Amer. J. Med.*, 1948, 5, 879), which I was invited to contribute as the concluding paper to a series of seminars on protein hydrolysates and pure amino-acid mixtures presented by a group of experts including Dr. Elman.

3 and 4. I freely admit being in error over the reference to the paper by Spence, Evans, and Forbes, and to the one by Dr. Elman. The work referred to in both cases is that by S. C. Werner (*Ann. Surg.*, 1947, 126, 169). On looking over my earlier notes I find that by some mischance the references became misplaced, though on again reading Werner's paper (para. 1) it does seem as if he is quoting Dr. Elman when he states, "To administer the equivalent of 90 g. of protein requires eight or nine hours and a volume of 2,500 ml."

I am grateful to Dr. Elman for pointing out these errors in my references.—I am, etc.,

Bucksburn, Aberdeenshire.

D. P. CUTHBERTSON.

Resistant Staphylococci

SIR.—The annotation entitled "Resistant Staphylococci" (Jan. 8, p. 64) raises the interesting and important question how much the bacteriologist can help the clinician in deciding the probable effect of penicillin in a particular case of infection due to a penicillinase-producing strain of *Staph. aureus*. The important question for the clinician is not how much penicillinase can be artificially extracted from a given organism, but whether the organism can produce the enzyme in sufficient quantity and quickly enough to permit it to grow in concentrations of penicillin obtainable in the human body. The double sensitivity test, using two different-sized inocula, is probably the most informative; and, as pointed out by Gilson and Parker, the difference is directly related to penicillinase production. Investigations of this type on 18 penicillinase-producing staphylococci recently isolated from cases of infection in this hospital gave the following results:

Greatest Concentration of Penicillin permitting Growth		No. of Strains
Large Inoculum (Approx. 1,000,000 Organisms)	Small Inoculum (Approx. 1,000 Organisms)	
50 or more u./ml.	1-4 u./ml.	7
50 or more u./ml.	0.25-0.5 u./ml.	5
25 u./ml.	1 u./ml.	1
25 u./ml.	0.25-0.5 u./ml.	2
12.5 u./ml.	0.25 u./ml.	1
12.5 u./ml.	0.03 u./ml.	1
1.0 u./ml.	0.13 u./ml.	1

It seems probable from these results that some of the strains would respond more readily to penicillin treatment than others, but there are still at least three unknown factors. First, what is the number of organisms penicillin is likely to encounter in a given infection? Secondly, do staphylococci produce penicillinase at the same rate *in vivo* as *in vitro*? And thirdly, does an organism which only produces small quantities of penicillinase acquire the ability to produce more in the presence of small quantities of penicillin?—I am, etc.,

Pensions for Diabetics

SIR.—My letter (Nov. 13, 1948, p. 875) has aroused many letters of criticism from many angles. It is impossible to deal with all, but I should stress again some facts that made me write the letter.

(1) The Army Pensions Board seems to be very generous in awarding pensions to diabetics in cases of grave hardships in the Services after which diabetes has soon followed. But the great majority of appellant cases referred to me arise in circumstances comparable with, or even less straining than, those of civilian life, certainly less tense and difficult than wartime London. If all persons developing diabetes outside the Services under comparable conditions were to be pensioned, well and good perhaps. But merely to deserve a pension because diabetes develops while on war or post-war service is the position which I criticize in relation to pension awards.

(2) It should not be forgotten that the recognition of diabetes as a pensionable disability contradicts a status of ordinary working health and capacity which most diabetics cherish. They want to be, and are, capable of housewifery and other full employment, except in some quite unsuitable jobs. They want to be accepted for superannuation and limited life assurance and not to be shut out from the posts that twenty-five years of

insulin have proved the majority to fill normally for many a year.

I have been accused of being "unsympathetic" and "hard-hearted" to diabetics in my written attitude about pensions, and this rather hurts me. I was solaced last week to receive an unexpected letter from Dr. Elliot P. Joslin, of Boston, Mass., who has done more than anyone else in the world for diabetics' interests for fifty years. He wrote to say he supported my attitude towards pensions "one hundred per cent." But I could never be 100% certain of any point of view I formed on diabetes, although this is what the legal attitude asks one to be.—I am, etc.,

London, W.1.

R. D. LAWRENCE.

Anuria

SIR.—Permit me to correct a misstatement which appears in the paper by Drs. D. A. K. Black and S. W. Stanbury on the treatment of anuria (Dec. 25, 1948, p. 1101) and in your leading article on that subject in the same issue (p. 1111). Drs. Trueta and Barclay and their colleagues did not demonstrate, neither did they describe, a *shunt* in the renal circulation. They showed that in the rabbit the application of a tourniquet to a hind limb for some hours, or the stimulation of (1) the central end of the cut sciatic nerve or (2) the distal end of the cut splanchnic nerve, resulted in a short-circuiting or a diversion, or, *more correctly stated, an alteration, of the blood-flow through the renal cortex*, so that the greater volume, practically the whole of the blood, subsequently flowed through the medulla (at increased rate), while the amount flowing through the outer- and mid-cortex was so far reduced as to fail to show radiographically.

The recent misstatements have arisen, probably, chiefly from a lack of understanding of the anatomy of the renal circulation, and it is well that correction be made now before these misstatements are referred to or repeated elsewhere. The renal circulation is primarily glomerular and is shown as (a) in the accompanying diagram: all the glomeruli are situated in the cortex, and the blood which flows through the great majority (about 85%) traverses the peritubular capillary plexuses of the cortex. The blood which flows through the most proximal glomeruli, those of the boundary zone (about 15%), passes to the medulla, whose normal (and sole) blood supply it is—hence the name juxtamedullary which I gave to these proximal glomeruli in 1941.²

When a limb tourniquet is applied, or the central end of the cut sciatic or the splanchnic nerve is stimulated, vasoconstriction in the renal arteries brings about greatest reduction in the calibre of the cortical (intralobular) arteries, so that the circulation in the outer- and mid-cortical glomeruli (circa 80%) appears to cease, while as a consequence the circulation through the juxtamedullary (15%) and some (5%) deep cortical glomeruli and the medulla is greatly augmented, the juxtamedullary glomerular capillary loop-velocity much increased and the renal circuit-time reduced by half (see (b) in the diagram).^{2,4}

In the group of conditions in which lower nephron damage is a common feature—blackwater fever, crush syndrome, incompatible blood transfusion, concealed accidental haemorrhage in pregnancy, excessive vomiting in pyloric stenosis, cholera, and yellow fever—it is most probable that the extreme reflex vasoconstriction of cortical vessels (above mentioned) does not occur, but rather is the partial renal cortical ischaemia due to an exaggeration of the normal autonomous control in the kidney by which the intrarenal blood flow is adjusted to the varied conditions of the general circulation. In discussing the

pathogenesis of the renal failure in the three conditions first mentioned Foy and his colleagues⁴ drew attention to the dehydration in such patients, and they concluded that the anuria is associated with the diminution of blood volume, of renal blood flow, and of glomerular filtration. It seems reasonable, therefore, to conclude that in respect of the reduced renal blood flow in these conditions the degree and duration of cortical ischaemia are determined by the autonomous control of the kidney which increases the tone of the renal arteries (in endeavour to maintain the renal blood flow in the face of reduced blood volume), producing proportionately greater vasoconstriction in the intralobular arteries, so that there is partial ischaemia in the outer cortex—(c) in the diagram. Anaemic anoxaemia from external or internal blood loss and pigment athrocytosis from haemoglobinuria or myohaemoglobinuria are to be regarded as additional factors in the pathogenesis of the tubular lesion and renal failure. Similar views are stated more fully in a leading article in the *Lancet*,⁷ and simple statement only need be made here to outline the intrarenal circulatory changes.

As regards true vascular shunts in the renal circulation such as those described by Steinach,⁸ Spanner,⁹ Trueta and his colleagues,⁵ and Simkin,¹⁰ the precise nature, number, and function of these are not yet fully understood.—I am, etc.,

Whither Tuberculosis?

SIR,—The letters from the pens of Drs. G. Lissant Cox (Dec. 25, 1948, p. 1118) and Stephen Hall (Jan. 8, p. 70) are valuable contributions to a survey of the present situation. Volumes might be written on "Whither Tuberculosis?" But may I take up a little of your space?

Everyone to-day has to try to encompass too much, and this in spite of specialization and the splitting up of medical practice. Again, procrastination and delay are too common because of the shortage of beds, nurses, and, to some extent, of properly trained doctors and their valuable and numerous assistants. These things are largely due to post-war conditions and to the haste, uncertainty, and incompleteness of present changes. Delay leads generally to the disadvantage of the patient.

The desire of sanatorium physicians to share in the work of the clinic and to study environmental factors is laudable: enlarging the vision and widening the interests are healthy desires. But sanatorium doctors must realize it is a whole-time job to look after the treatment of the patients under their care. To make a complete diagnosis of the whole position is a first requisite of good treatment. In so far as this may necessitate a delving into causal factors, physical and mental, it may involve a study of sociological conditions and much else.

But the first duty of the sanatorium physician is to master all the details in the treatment. For example, an artificial pneumothorax is not a simple form of treatment, as Dr. Hall has pointed out. The complications which arise in its course are lessened and the end results improved according to the skill, experience, and clinical instinct of the managing physician; and this depends even more upon his competence in carrying the treatment along and through than upon his judgment on the choice of the patients for this particular form of collapse therapy. Furthermore, apart from the necessity of keeping abreast of the developments of thoracic surgery in order to use his acumen as a physician in supervising what to do and when to do it, the introduction of specific drugs and a closer supervision of the early stages of the rehabilitation of the patient all keep the sanatorium physician busier than ever. Perhaps the day has gone by when men of the stamp of Peter Edwards—to name only one—can make valuable contributions to many branches of the combating of tuberculosis.

So again I say, no longer can we repeat, as once was done, that prevention and cure go hand in hand. Whatever can be said about prevention and treatment going together in theory, in practice to-day they must be separated (*pace* Dr. Lissant Cox), otherwise "many will overlap and wrestle with too many details." By the way, I can make out neither head nor tail of one of Dr. Lissant Cox's sentences—"Tuberculosis, environmental and clinical, now merges into a general medical directive." This is a bit of new jargon to me. And I am a little puzzled by his, "If the new chest physician . . . exalts diagnosis and treatment and ignores prevention, he may gain entry into the . . . portals of general medicine but will have lost his soul." I would like every chest physician to "have his feet on the ground" in general medicine before he ever specializes.

It seems to me that the ways of collaboration between the chest physician and his colleagues in various other spheres are complicated and have by no means been worked out yet.—I am, etc.,

Mundesley, Norfolk.

S. VERE PEARSON.

SIR,—The letters of Dr. G. Lissant Cox (Dec. 25, 1948, p. 1118) and Dr. Stephen Hall (Jan. 8, p. 70) express some of the anxieties that are troubling many of us who are employed in the tuberculosis service. Both are worried by the apparent disintegration that is taking place at many levels and in certain aspects of the service. Some of the troubles are administrative and are the result of the National Health Service Act. One hopes that with advocates such as Dr. Lissant Cox and Dr. Stephen Hall to guide our destinies many of these difficulties will be overcome in the not too distant future.

Another change about which they are both concerned is the drift of the tuberculosis officer away from social and preventive medicine to "clinical" medicine; this is surely a symptom of our nursing shortage—hence shortage of beds for the assessment and treatment of the patient's disease. The tuberculosis officer is forced to use the bed available in the patient's home and his relatives to do the nursing. With an inevitable wait of six months before "active" treatment can be started in hospital or sanatorium he is greatly tempted to do something for his patient. Through no fault of his he has entered the field of treatment, a time-consuming business, and at the expense of his other functions.

Little has been said about the training for this specialty; the success or failure of the service depends on the medical merit it attracts. Rightly the emphasis in undergraduate training is on diagnosis, but it is still the practice to teach this at the bedside rather than at the chest clinic. Most postgraduate courses (Wales excepted) are held at sanatoria or university centres: why not the chest clinic or out-patient department?

The undergraduate has little time in his curriculum for social medicine; this he must learn later in general practice or some special centre. Advertisements for tuberculosis officers now uncommonly require a candidate to have a higher degree in clinical medicine: experience in general practice or social or preventive medicine is seldom asked for. It is possibly better that the potential chest physician should not be recruited from the medical officer of health's department, but it is equally unwise that his sole experience in tuberculosis should be gained treating the disease in hospital while working for higher degrees. If plans are being laid for the training of specialists in tuberculosis it is very necessary that experience in all branches of the specialty should be included if one is to stop this drift to "clinical" medicine which your correspondents foresee.—I am etc.,

Isleworth, Middlesex.

CHARLES J. STEWART.

SIR,—The letters of Dr. G. Lissant Cox (Dec. 25, 1948, p. 1118) and Dr. Stephen Hall (Jan. 8, p. 70) express a general anxiety felt at the moment by many workers in the old tuberculosis service. The necessity for a sustained campaign against the disease, using every possible method of control, direct or indirect, is so obvious to those with practical experience of the problem that any development which might appear to threaten it is naturally suspicious.

This suspicion should not be interpreted as an indication that the tuberculosis service was regarded as perfect by those who worked in it. Far from it: the greater part of constructive

criticism over the last few years has in fact come from the service itself. The increasing complexity of diagnosis, the development of certain aspects of therapy in the dispensaries, and the ever-increasing numbers of cases of all kinds referred to them were recognized as a new responsibility requiring improved facilities, experienced staff, and a closer contact with other branches of medicine. Much has already been achieved, and the natural step now is to establish the modern type of clinic as a special hospital department like any other, with attached beds for diagnosis and assessment and treatment for "short-term" and emergency cases as may be appropriate.

It has also been suggested, and this is what Dr. Hall particularly questions, that the chest physician should have control of sanatorium beds, on the grounds that his experience of his specialty should be complete and a better continuity of control of the individual case established. This arrangement may or may not come about; there are arguments on both sides and it may in the end be found appropriate to one set of circumstances and not to another. Yet even without it there is certain to be an over-all increase in clinical responsibility on the part of the tuberculosis physician. It is thought that this may result in a diminished interest in the environmental and preventive aspects of the problem and that the conception of a really comprehensive tuberculosis service will be more difficult to maintain.

To add to the anxiety on this point, the responsibility for environmental and preventive work, rehabilitation, financial aid, and so on has been placed with other authorities, a matter already widely commented upon as introducing a distinct cleavage in what should be a single entity. Altogether there is need to watch developments very closely lest the attempt to meet well-recognized defects should result in the creation of new ones.

The new facilities made possible by the legislation of recent years must, however, be used to the full. Several important points come to mind, but there are two which if recognized will do much to achieve the desired end. First, the local area clinic must be regarded as the centre for the direction of anti-tuberculosis measures as a whole, and its medical staff permitted to exert a guiding influence over any outside organization concerned with the welfare of the individual patient or with the problem generally. Only in this way can the activities of the various authorities concerned be knit together into an effective comprehensive effort. Secondly, the training of staff for the senior specialist appointments must be thorough. There is a tendency in some quarters to regard a basic training in general medicine and in chest medicine as sufficient. This should certainly be the foundation, but it is not enough. Experience in sanatorium and in the chest clinics is the only way to obtain a true insight into the special characteristics of the disease and a clear understanding of the importance of epidemiological and environmental factors. Such experience should precede the appointment to a senior post. This would go far to ensure that the problem would be dealt with as a whole, without any particular aspect of it being neglected.

Finally, the multiplicity of authorities now involved will inevitably make administration difficult and complex. Auxiliary staff to deal with the detail of administration and the social side of the work must be adequate, and unless everyone appreciates the fact that the system is merely a means to an end the whole scheme will suffer. This is of the first importance in dealing with such a complicated problem as the control of tuberculosis.—I am, etc.,

Theydon Bois, Essex.

HUGH RAMSAY.

Anaesthesia in Ludwig's Angina

SIR,—Dr. John H. Willis (Jan. 1, p. 31) raises the question of anaesthesia in operations undertaken for the relief of acute inflammatory conditions in the neck. As he implies in his letter, the problems involved are not universally recognized even to-day. Chevalier Jackson stated that he considered the cause of death in many cases of Ludwig's angina to be respiratory failure as a result of the administration of sedative drugs. He based this conviction on the fact that many patients sent to him suffering from this condition were either moribund or dead on arrival, although they had started their journeys as healthy persons apart from the local condition; in all cases the common factor was the administration of morphine or other seda-

tive by well-intentioned practitioners in order to render the patients comfortable for the journey to Jackson's clinic.

The explanation of the sequence of events is clearly described by Macintosh and Bannister.¹ Briefly it is that the conscious patient is able to compensate for the early stages of respiratory obstruction by using his accessory respiratory muscles. As long as this extra thoracic effort maintains the alveolar oxygen tension at a sufficient level the patient will remain conscious. If, however, the condition is not relieved, the accessory respiratory muscles will become fatigued. Alternatively, the administration of a sedative drug will depress the respiratory centre, with consequent diminution in respiratory muscular efficiency. In either case the result is the same: the alveolar oxygen tension falls, the vital centres become anoxic, and the patient quietly stops breathing—usually without even developing laryngeal spasm.

All agents which produce unconsciousness are to a greater or lesser degree respiratory depressants at some stage in their action, and it therefore follows that to induce unconsciousness as a preliminary to surgical intervention in cases of Ludwig's angina is to court disaster. The three agents named by Dr. Willis—"pentothal," cyclopropane, and chloroform—are all potent respiratory depressants and are in my opinion contraindicated as inducing agents in the type of case under discussion unless a certain preliminary step is taken.

The rational preliminary approach to anaesthesia in cases of respiratory obstruction resulting from Ludwig's angina, carcinoma of the thyroid, and injuries involving the upper respiratory tract is either to perform a tracheotomy under local analgesia or to pass an endotracheal tube after "cocainizing" the larynx. This latter procedure is easily accomplished with the aid of a Macintosh or a Kenton spray. Kuhn's observation² that laryngeal intubation enables the surgeon to become and remain master of the field is probably never better exemplified than in this method of anaesthetizing such cases of respiratory obstruction, for when the field has been mastered by laryngeal or tracheal intubation any general anaesthetic agent may safely be used, according to the indications present, to induce unconsciousness and enable the surgeon to relieve the pathological condition.—I am, etc.,

Bristol

- ² *Arch. Rhinol. Laryng.*, 1911, 25, 95. (Quoted by Gillespie, N. A., in *Endotracheal Anaesthesia*, 1948, p. 34, Wisconsin.)

SIR,—Dr. John H. Willis (Jan. 1, p. 31) comments upon the danger of using intravenous anaesthesia for the incision of acute inflammatory swellings of the neck, and I would like to carry the question one stage further back. Surely no "resident" (and here I use the term to refer to a man within a year or so of qualifying) should be expected to undertake the responsibility of anaesthetizing a patient with Ludwig's angina; the operation is rarely so urgent a matter that an experienced anaesthetist cannot be obtained.

Some residents seem frequently to be asked (or told) to give anaesthetics to dangerously ill emergency cases. I recall a well-known anaesthetist who was asked what advice he would give to a resident who had to deal with an acute intestinal obstruction; and his significant reply was, "He shouldn't: it's a specialist's job."

A "post-operative chest" following a simple herniotomy or other cold case may be regarded as a disgrace by some, but it appears that in some circles such a complication is looked upon almost as the rule after a serious upper abdominal emergency operation. Such complacency is tragic, especially when this added condition may well tip the balance fatally for the patient. So grave a responsibility surely should not rest on the shoulders of a junior but of a specialist.—I am, etc.,

Essex, Essex.

ERIC K. GARDNER.

Spinal Anaesthesia for Caesarean Section

SIR,—We feel that the statements of Mr. D. Stanley-Jones (Dec. 25, 1948, p. 1121) on this subject cannot be allowed to go unchallenged. It is true that there have been cases of collapse during caesarean section under spinal anaesthesia, both reported and unreported. But the fact remains that others who have developed safer techniques, including the use of smaller

dosages, have reported large series of cases with no fatalities attributable to this method of anaesthesia. Resnick,¹ Thomas,² and Malkin³ have reported between them more than 1,200 cases without a single anaesthetic death.

One of us has used spinal anaesthesia for caesarean sections over a period of more than ten years without observing the effects described by Mr. Stanley-Jones. Instead of the "massive vasodilatation of the largest and bloodiest organ in the body" we have invariably found caesarean sections under spinal anaesthesia to be associated with greatly reduced bleeding from the uterus, which contracts unusually well. Other authors have reported the same finding.^{1,2,4} Recent work has shown that, provided adequate oxygenation and capillary circulation is maintained, even a severe fall in blood pressure need have no untoward effects on the patient. However, there is no difficulty in maintaining the blood pressure within normal limits with the aid of "methedrine."⁵ The danger lies not so much in vasomotor "collapse" as in respiratory paralysis.^{6,7} The gravid uterus, filling and distending the abdomen, interferes with the descent of the diaphragm. If to this is added intercostal paralysis extending to a high segmental level, grave anoxia may occur rapidly and insidiously. We have seen this happen on two occasions. Once in the presence of a large ovarian cyst, and once at the beginning of a caesarean section. In each case inhalation of 100% oxygen, or inflation of the lungs with oxygen, prevented any serious consequences, and in each case respiration returned to normal after removal of the abdominal tumour.

It is now becoming generally recognized that for caesarean section analgesia should be limited to the level of the xiphisternum. This means in practice a smaller dose than that usually used for appendicectomy, for instance. If this is done, respiratory embarrassment is avoided, but as a precaution an efficient means of inflating the lungs with oxygen should always be available for immediate use in emergency, and the uterus should be emptied while "controlled respiration" or 100% oxygen inhalation is maintained. The steep head-down tilt adopted in the belief that this will assist the blood pressure merely increases the respiratory embarrassment and makes matters worse. Also, when using "gravity-controlled" solutions it should be remembered that the spinal curves are altered in late pregnancy. We are now using an isobaric solution of amethocaine diluted with spinal fluid to a concentration of 1 in 1,000. We find that 8 to 10 ml. is quite adequate for caesarean section, although 12 ml. would normally be used for, say, a hysterectomy.

From the foetal standpoint spinal anaesthesia is ideal, as the babies usually cry as soon as their noses are born and they are free from the effects of respiratory depressants. The method is therefore especially valuable with premature or otherwise handicapped babies.

To deride as malpraxis a method which has over a period of years given such good results in the hands of experienced obstetricians is unworthy of your columns. We feel that so long as attention is paid to the precautions described spinal anaesthesia remains a safe and effective procedure in the absence of shock or severe bleeding, and it is especially valuable when caesarean section is performed in the interests of the baby.—We are, etc.,

Breast-feeding

SIR,—After having read Dr. James S. Hall (Jan. 8, p. 72), especially where he states that mothers are relinquishing the almost impossible task of synthesizing wholesome milk from snock, scraps, and sausage meat, I feel still more ought to be added to the recent controversy on the subject of breast-feeding.

Although of course the present-day rations contain substantially more and better items than those mentioned by Dr. Hall, it is only too well known that most inadequate nourishment of

the mother still assures a very high quality breast milk. I have spoken to doctors, and also with mothers, who have survived Hitler's concentration camps, and they were unanimous in saying that many children were born in these camps and all of them had to be breast-fed, as no other milk was available. The mothers often dying in the last stages of pulmonary tuberculosis still often managed to breast-feed their babies, and it was only in cases of extreme dehydration, when the mother was suffering from dysentery, etc., that one had the pathetic spectacle of seeing a mother putting the baby to a dry breast.

In addition I should like to say that Dr. Hall's belief of the equality of breast milk and the baby foods must be based on the knowledge that all the known chemical substances contained in breast milk are present in the artificial products. But even the most biochemically inclined paediatricians know that there are many other, mostly as yet unknown, factors present which make breast milk the superior nourishment.

The recognition of the importance of breast-feeding seems not only well established everywhere, but is increasing; this conclusion I draw from the fact that to-day in case histories, not only of babies but of younger and even older children, the mode of feeding as an infant has its definite place.—I am, etc.,

Whitehaven, Cumb.

JOHN ABELS.

SIR,—Picking up my *Journal* of Jan. 8 I find first (at p. 59) a very favourable review by Professor Charles McNeill of my book on breast-feeding, in which he remarks that "paediatricians proclaim and extol its importance"; and then, turning to a later page (p. 72), I find Dr. James S. Hall again taking up the cudgels for the bottle-fed infant. I am sure that Dr. Hall is right in saying that his cases of fully fed bottle babies compare very favourably with the under-fed breast babies which appear to be common in his practice. In my own practice, however, where no baby is underfed, whether it be on the breast or on the bottle, I do find a very real difference in morbidity rates between the two.

As feeding problems are attended to at the surgery, where I hold a weekly weighing and consultative session, my visits are genuinely for sickness. I have collected and recorded (the results are to be published shortly in the *Lancet*) the visits required during the first year of life by 100 consecutive babies in my practice. Briefly, the bottle babies required more than five times as many. Moreover, 73% of the breast-fed babies did not require a visit at all, as compared with 9½% among the artificially fed. In the present days of National Health Service and payment by capitation this argument for breast-feeding should at least appeal to the general practitioner, if only through his pocket.

I note that Dr. Hall, and the Dr. Hutchinson whom he quotes, are considering these children from the point of view of "adulthood or later life." I do not deny that the bottle-fed child may achieve both health and immunity in later life; but I prefer to save the mother the worry of the higher incidence of disease in infancy. What simply appals me is his picture of "maternal unhappiness and misery" caused by breast-feeding. None of my lactating mothers is unhappy or miserable. If they were, of course, they would undoubtedly underfeed their babies.—I am, etc.,

York.

F. CHARLOTTE NAISH.

SIR,—Dr. J. S. Hall (Jan. 8, p. 72) is still not impressed. In his first letter (Nov. 20, 1948, p. 919) he said: "I cannot determine that artificial feeding has any deterrent effect whatsoever. . . . I am of course open to conviction should sufficient modern evidence be available to the contrary." I have supplied him with some evidence; but he passes it off with a light laugh because it comes from America, and is, he infers, a sort of medical Marshall aid.

The reason I quoted American figures was that this is the largest series available. By a *petitio principii* Dr. Hall chooses to ignore the data on pyloric stenosis (despite the fact that the series was not lease-lent, but came from Westminster). Of 46 bottle-fed babies with pyloric stenosis 5 died. Of 100 breast-fed babies with the same disease none died. If Dr. Hall (or any other reasonable person) were told that his next infant was destined to suffer from congenital pyloric stenosis would he still allow it to be artificially fed?

It may be that in England now (owing to the lack of domestic help, or the snook, or some other factor) artificial feeding is easier than breast-feeding; but, Sir, the *British Medical Journal* goes all over the world. Please do not let us disseminate any authority from the medical profession for a further decline in breast-feeding.—I am, etc.,

Bristol.

HUGH R. E. WALLIS.

* This correspondence is now closed.—Ed., *B.M.J.*

Rhesus-testing in Pregnancy

SIR,—Doctors engaged in the practice of midwifery are now well aware of the importance of blood replacement in the treatment of the haemorrhages of pregnancy. Increasing use is therefore being made of the emergency resuscitation services which most maternity hospitals maintain for the purpose of transfusing women too ill to be removed into hospital.

It is, however, evident that some practitioners do not realize that blood transfusion cannot be undertaken with safety unless the rhesus status of the patient is known. The blood group can be determined at the bed-side, but the rhesus grouping can be ascertained only by a somewhat elaborate laboratory technique.

As one who has had some experience in emergency transfusions I write this letter to urge on all doctors responsible for the care of pregnant women the necessity to take steps to determine early in pregnancy the rhesus grouping of the patient. Too often one is summoned to women critically ill from blood loss only to find that the rhesus status is unknown, thus increasing the hazards of blood replacement. It is the bounden duty of all doctors who make themselves responsible for the care of the pregnant woman to see that the rhesus grouping is carried out as early as possible in the pre-natal period. The doctor who neglects this precaution is most certainly failing in his duty to the mother and her child.—I am, etc.,

Sheffield.

W. J. CLANCY.

Senile Deterioration of the C.N.S.

SIR,—I was very interested to read the article by Dr. Trevor H. Howell on senile deterioration of the central nervous system (Jan. 8, p. 56). I must, however, disagree with the conclusions reached. In assessing central-nervous-system physical signs in this age group, one important factor seems to have been omitted—namely the state of the vascular system. In addition the defective absorption of vitamins must be considered—achlorhydria being a not uncommon “normal” finding in this age group.

Any attempt to explain these phenomena by a central lesion seems to me erroneous. I would say that the factors operating are: (1) peripheral vascular occlusion which, although not gross clinically, has been sufficient to impair the blood flow to the vasa nervorum of peripheral nerves; and (2) vitamin B deficiency, which has again led to peripheral nerve lesions and also to mid-brain lesions with pupillary changes.

It is then on a basis of a peripheral neuropathy that I would explain the lesions found. In support of this I note that the pyramidal tracts are normal in practically all cases, and lesions in the legs are more pronounced than in the arms—a not uncommon finding in peripheral vascular disease.—I am, etc.,

Leeds.

RAYMOND C. GLEDHILL.

Cotton-dust Disease

SIR,—The following quotation is from your leading article (Dec. 18, p. 1069): “It seems more likely, however, that there are only two diseases, perhaps only one: mill fever is almost certainly the early stage of byssinosis, and the remaining two conditions are very similar to other diseases caused by mouldy organic matter such as grain, flax, hemp, jute, and bagasse.” This is not correct. There are three distinct conditions, distinct clinically and occupationally.

1. *Mill Fever*.—This will affect anyone unaccustomed to cotton mills, whether spinning mills or weaving sheds. It is a very mild febrile attack with anorexia after a day in the mills. After a night's sleep it is gone, giving protection, which, however, disappears if the visits to the mills are discontinued. I have often experienced it.

2. *Strippers' and Grinders' Asthma*.—This is a very chronic disease which takes many years to develop. It only concerns

men in spinning mills exposed to dust arising from raw-cotton bales. It is not seen in weaving sheds or among those who tread the spinning frames and self-acting mules to which the cotton sliver proceeds from the carding engines. I was the first to describe the condition in 1908.

3. *Weavers' Cough*.—This condition is only seen among cotton weavers, and only among weavers preparing cotton cloth for the bleachers and dyers. If the cotton thread being woven for this purpose gets damp on the warp beams, under conditions described by me in 1914, offensive moulds may grow on the threads, which become dark and smell badly. When such threads are woven the operatives experience epidemics of acute illness lasting several months and clinically resembling active pulmonary tuberculosis.

What byssinosis is I have often wondered. Βύσσις is a Greek word for linen.—I am, etc.,

Lossiemouth, Morayshire.

EDGAR L. COLLIS.

Mallet Finger

SIR,—Perhaps it is wise first to define the deformity “mallet” finger as a lesion of the mechanism controlling extension of the terminal joint of any finger (the thumb is excluded).

From experience in the treatment of this very common industrial and domestic lesion we suspected that it was not a simple problem, and that the pathological anatomy of the tears might be as varied as the end results we observed to follow routine plaster immobilization with flexion of the proximal joint and hyperextension of the distal interphalangeal joint. Following this routine we were not unduly worried when flexion of the terminal joint persisted at the end of treatment; as Dr. W. J. Lloyd (Jan. 1, p. 30) has observed, most workmen can accommodate themselves to this deformity and are not concerned with the appearance of a useful working finger. (Precision workers, however, find the loss of complete control of the terminal joint of the index or middle finger a real working disability.) We were worried, however, by a group who after treatment complained of such pain in the distal interphalangeal joint that they could not return to work, and this pain persisted for a long period.

Therefore six years ago this hospital undertook a planned investigation of the problem, continued its close study for almost two years, allowed a period of time to elapse before assessing all the patients included in the study, and finally published a detailed description of the varying surgical anatomy of these tears and a detailed account of the end results to be expected after surgical treatment.

From this study it is obvious, I think, that mallet finger cannot always be treated by a reassuring word, as Dr. Lloyd would seem to suggest. The open mallet finger caused by a grinding wheel, cutting or crushing violence—a not infrequent industrial injury—is an undisputed surgical matter.

The closed mallet finger, which may cause very troublesome and prolonged pain in the joint, is caused by the avulsion of a fragment of bone from the base of the terminal phalanx, taking with it a variable amount of articular cartilage. If the very disabling and painful traumatic arthritis of the joint is to be avoided, then early and accurate reduction of the fracture, in our view, is essential. If closed reduction fails, as it sometimes does, then early open reduction with internal fixation is essential.

The fracture type of mallet finger accounted for 25% of our series. Three-quarters of our patients had tears of the extensor tendon at varying levels, the level of the tear presenting its own problem in treatment—e.g., if any part of the tear was situated proximal to the joint, the prevention of adhesions between the tendon and the neck of the middle phalanx with the subsequent inability of the tendon to pull the joint into full extension still remains a problem.

The prognosis after surgical treatment of mallet finger seen early is not as bad as Dr. Lloyd's impressions indicate. In a close study of 61 consecutive mallet fingers treated by surgery, 20 regained full extension and a good range of flexion, the remainder had flexion deformities ranging from 10° to 30° and a good range of powerful controlled flexion. In the treatment of this condition there is undoubtedly an economic angle—we can both over-treat and under-treat: to do either may be unnecessarily expensive.

In my experience a common type of mallet finger is the partial tear in the middle-aged. The patient presents a terminal

joint with 20° to 30° flexion deformity with an ability to fully flex the joint and extend it to 20° or 30° of its full range. If such a tear is not associated with a fracture there is, I believe, a real place for the "reassuring word" in treatment. Most workmen can continue most jobs with such a finger, and within four or five weeks have accommodated themselves completely to the disability. The reassuring word, however, has no place in the economic treatment of the fracture type of mallet finger with extensive articular cartilage involvement. Symptoms of traumatic arthritis can be very prolonged. The treatment of painful arthritis by arthrodesis of the joint involves many months before the joint is so soundly fused that the finger has regained powerful and painless function.

The surgical and economic treatment of mallet finger is not a simple matter; it demands a clear understanding of the underlying pathology, very skilled technique in active treatment, and a degree of judgment in assessing those to treat and those to leave alone.—I am, etc.,

Classical Caesarean Section

SIR,—The recent correspondence on the merits and demerits of the classical caesarean operation has had a good deal of interest, mainly reminiscent, and the views of my own generation will of course stay coloured by the excitement we experienced some twenty years ago when we found that with the lower-segment operation post-caesarean peritonitis need no longer be a dread, and that at last we had a conservative alternative to the high forceps operations and the perforations. This then seemed more important even than the risks of later rupture of the scar. Nowadays, although the risks of infection no longer bear the same weight, most would agree that technically the lower-segment operation is much sounder, and until the other week I would have said from the experience of quite a number of cases that it could always replace the classical operation. I then met the following case.

A primigravida had a transverse lie which could not be corrected. The usual lower-segment operation was begun. The anaesthesia used was gas, ether, and curare. After opening the abdomen I could not correct the oblique lie and extract the child, either as a breech or a vertex, so firmly was the uterus moulded round the child. The situation was exactly similar to a failed internal version for a shoulder presentation. In order to deliver the child it was necessary to make a free longitudinal incision upwards into the body of the uterus. This left an unpleasant T-shaped wound to be stitched.

Part of the difficulty may have been due to the oxytocic effect of the curare, and it might have been avoided by a deep relaxing anaesthesia, but deep anaesthesia is no proper solution to this sort of problem, and should I meet another case in which the uterus is contracted down on a transverse lie I would give serious thought to the advisability of an elective classical operation.—I am, etc.,

Liverpool.

PERCY MALPAS.

Carcinoma of Cervix

SIR,—My attention has just been called by a doctor long in practice in Kenya to the letter of Dr. E. Malcolm Clark (Dec. 4, 1948, p. 999) in which he attributes the relative freedom of Jewish women from carcinoma of the cervix to "some racial factor which we do not as yet fully understand," and disputes my conclusion that they are protected from the disease by the circumcision of Jewish males in infancy. He records a personal experience of twelve cases of carcinoma of the cervix among 82 cancers in Kikuyu women.

My correspondent says, "I feel that in fairness to you Dr. Clark should have made it plain that circumcision as practised by the Kikuyu differs in some important respects from circumcision as practised by Jews. Kikuyu males are circumcised in or about puberty, and the operation is so performed that a large spur of preputial tissue remains, extending outwards on each side of the fraenum. It is very characteristic of the Kikuyu . . . the Kikuyu attach great importance to this tag of tissue."

It is hardly surprising that late and partial circumcision fails to give the female as much protection against cervical carcinoma as the complete operation in infancy. East Africa, with its

complex mixture of circumcised and uncircumcised tribes and its primitive codes of sexual conduct, is not a field where unequivocal evidence on the subject can be obtained. In Fiji, on the other hand, where 90,000 circumcised Fijians live alongside 70,000 uncircumcised Indians without mixing, during the year 1925–32 the Suva Hospital admitted only three cases of cervical carcinoma in Fijian women and 26 in Indian women. I have no statistics of penile carcinoma in Fiji, but my attention was drawn specifically during my visit to its occurrence in Indians and its absence in Fijians.

The evidence from Fiji shows that circumcision, even done as late as puberty, has much protective value for the female. I also negatives the postulated racial immunity of Jewish women. Hoffman's statistics for Amsterdam (1919–29) showed a high incidence of cancer of the breast, rectum, liver, and gall-bladder among Jews than among non-Jews.

In conclusion let me say that I have never advocated the general adoption of circumcision in this country. I believe that all its advantages could be obtained without removal of tissue by the simple operation of universal dorsal preputiotomy in the first days of life.

I am indebted to the medical superintendent of the Suva Hospital for the information that from January, 1947, to November, 1948, twelve cases of malignant uterine tumour in Indians have been admitted and only a single case in a Fijian.—I am, etc.,

London, W.1.

W. SAMPSON HANDLEY.

Pre-suppurative Amoebic Hepatitis

SIR,—Dr. J. T. Harold (Dec. 11, 1948, p. 1034) states that no recent record exists of an amoebic abscess in a patient who had never been abroad. Dr. Francis Lowe (Jan. 1, p. 31) records a case, and I should like to report a second.

A male patient, aged 54 years, recently died in this hospital. He was admitted six months previously with an empyema of the right pleural cavity; there was no previous history of diarrhoea. Three months after admission he developed a typical amoebic dysentery motile vegetative amoebae being found in the stools and later in the pleural pus. Surgical treatment and emetine therapy were of no avail, and the patient died six months after admission. A necropsy revealed an amoebic abscess of the right lobe of the liver which had tracked through the subphrenic space into the pleural cavity. The patient had lived nearly all his life in Bolton and had never left this country.

—I am, etc.,

Townleys Hospital, Bolton.

M. W. JOHNSTONE.

Estimation of Prothrombin

SIR,—The report of the meeting of the Medical Society of London (Jan. 1, p. 26) contained statements concerning the control of dicoumarol therapy which might lead to misunderstanding. It is of great importance that ambiguities concerning the estimation of prothrombin should be avoided. Accidents have occurred in the past during dicoumarol treatment because of lack of appreciation of the many pitfalls encountered in the calculation of results and the confusion which exists in their interpretation.

Dr. Paul Wood is quoted as saying that the prothrombin concentration should be kept to "round about 30 to 40 mg. per 100 ml." Mr. Dickson Wright is said to have stated that "when less than 20 mg. per 100 ml. no dicoumarol was given. If the figure fell below 10 units (my italics) menadion bisulphite 30 mg. was given intravenously." In these two statements the prothrombin concentration is expressed both in "mg. per 100 ml." and in "units," neither of which is a customary procedure in this country. So far as I am aware there is no routine method for the estimation of prothrombin in milligrammes. It is nearly always expressed as a percentage of the concentration found in normal plasma, and it seems likely that the above quotations should read "30 to 40%," "20%," and "10%" respectively. If this is so, the minimum safe level advised by Mr. Dickson Wright is only half of that advocated by Dr. Wood.

It is not sufficiently realized that when prothrombin is estimated in dicoumarol plasma by a one-stage method^{1,2} the result depends upon the technique employed. It varies with the thromboplastin³ and also with the diluent used in the construction of the reference curve. Thus, if reference curves are

constructed by saline dilution of normal plasma and prothrombin is estimated in a dicoumarol plasma using venom-lecithin as thromboplastin,² the result will be higher than when brain emulsion¹ is used and very much higher than the result obtained with ox-lung extract.⁴ If the prothrombin is estimated by the two-stage method³ the result will probably differ from all three of those obtained by the one-stage procedures, though it will be nearest to that found by using venom-lecithin as thromboplastin.⁴ Not only is the reference curve obtained when prothrombin-free plasma is used for diluting normal plasma entirely different from that obtained when saline is used, but curves obtained with different prothrombin-free plasmas differ from one another, depending on the method used for the removal of the prothrombin.⁵

It is therefore important that any criteria for the limits of safety in dicoumarol therapy should be accompanied by a precise definition of the method used for the estimation of prothrombin. Differences in technique probably account for the apparent discrepancy which appears in your report between the recommendations of Dr. Wood and Mr. Dickson Wright.—I am, etc.,

Temperature Recording

SIR,—Professor Alan Moncrieff and Dr. B. J. Hussey (Dec. 4, 1948, p. 972), as well as the author of the annotation (p. 991) on temperature recording, overlooked the basic fact, often noted in "Any Questions?", "Correspondence", and "Notes and Comments" (*British Medical Journal* since 1943), that it takes ten minutes for the mercury clinical thermometer to reach stability with the temperature of the surrounding media irrespective of the site. Orally there may be an appreciable difference of 0.2°–0.5° F. (0.1°–0.25° C.) between a 2–3-minutes reading and one of 10 minutes; the same difference may also be noted between a site under the tip of the tongue (the usual site the nurse chooses) and further back at the side of the faenulum.

While it requires great care—traumatic recto-urinary fistula from a thermometer may occur (*Medical Annual*, 1946, p. 53)—the rectal method, being the least sensitive to the atmospheric environment, is the best. In the ambulant patient the oral may be as misleading as the axillary; this was noted by the late Sir Thomas Lewis in the low-grade fever of bacterial endocarditis (*Diseases of the Heart*). Even during the diurnal cycle the maximum difference between oral and rectal (5–6 cm.) temperatures varies from 0.6°–1.2° F. (0.3°–0.7° C.), approximating on the upgrade and diverging on the downgrade, but the nexus may be neither proportionate nor constant. Allowance, of course, must be noted for the slight deviation of individual thermometers.

With low-grade fevers, as for example in rheumatic carditis, cited by the authors, the pyrexia may recur regularly or irregularly at times other than the usual maximum periods of 1 p.m., 7 p.m., or 11 p.m. Accurate thermometry would abolish much of the unnecessary routine laboratory tests in many chronic febrile diseases. Active rheumatic infection rarely may be present, as shown by the B.S.R. and leucocyte count, even if the normal rectal range of 97.7°–99.5° F. (36.5°–37.5° C.) is not exceeded; when the maximum rectal temperature is around 99° F. (37.2° C.) quiescence is assured (by the laboratory tests, the sleeping pulse, and the absence, at rest, of mild sensible perspiration day or night) in such cases.—I am, etc.,

Dublin.

A. D. MACDOWYER.

Spontaneous Amputation of Cervix

SIR,—As an interesting contrast with Mr. Walter Calvert's report (Jan. 8, p. 58) of difficult labour following surgical amputation of the cervix uteri, I beg to recall, in retirement, the following case.

Between 30 and 20 years ago a midwife summoned me to see something she did not understand in the vulva of a young primipara

after a normal, easy labour. Delivery was complete; the placenta and membranes were normal, and there had been no undue haemorrhage.

I found it to be a plum-coloured fleshy mass which I had no difficulty in recognizing as the whole undilated cervix, 1–1½ in. (2.5–3.75 cm.) in length, the os being about ½ in. (0.6 cm.) in diameter. Since it was attached by only a shred of tissue anteriorly I snipped it off and gave it subsequently to Professor Carlton Oldfield for the museum of the Leeds School of Medicine. It was clear that the child had been born through the split in the cervix at or near the internal os. The puerperium was normal.

Within two years the midwife called and told me that the patient had had another baby, born in a labour so quickly and easily that even she had not been able to get there in time. Again recovery was normal.

Can it be that a woman can amputate her own cervix better than even the most skilful gynaecologist?—I am, etc.,

Totland Bay, L.o.W.

W. ARNOTT.

Lithium Ionization for Gout

SIR,—As one who has derived much personal benefit from lithium ionization in the treatment of an acute attack of gout. I deprecate the slighting reference to this treatment in the annotation on physiotherapy (Dec. 25, 1948, p. 1114). In the early days of my career I practised electrotherapy at a time when accurate medical ionization had only recently been introduced by Leduc and Lewis Jones, and I did some research and published papers on this subject.^{1,2} The effect of lithium ionization in many cases of acute gout is extremely striking, because it commences immediately. I have had a patient come into my consulting-room on crutches who at the end of the treatment was already able to walk on the affected foot. Other patients have come to me repeatedly to abort successive attacks. I looked up the reference to Sir Henry Cohen's article, and this by no means makes the sweeping condemnation suggested in your annotation. Actually lithium ionization is not mentioned, and the reference to lithium is probably to oral medication.—I am, etc.,

London, W.1.

POINTS FROM LETTERS

Manganese Therapy

Dr. C. A. ALLAN (Dundee) writes: Recent additions to the knowledge of the biochemistry of manganese have shown it to be concerned with antibody formation (Walbrun, L. E., *Acta path. microbiol. scand.*, 1944, 21, 3; Petherick, M. H., *et al.*, *Proc. exp. Biol.*, N.Y., 1944, 59, 254), and also that it is an activator of a number of important enzymes. . . . This has suggested to me that there may be other and as yet unexplored uses for manganese therapy, among which sensitization dermatitis, as a derangement of the body's normal defence mechanism, may possibly be included. With the object of testing this hypothesis manganese was recently used in two cases. The first was a bus driver, aged 39. From 1940–5 he was a motor transport driver in the Army, always in contact with diesel oil. He developed local skin irritation on legs and arms. From 1945–8 he had frequent absences from work as a bus driver; he was still in contact with diesel oil. He remained resistant to all treatment until colloidal manganese was used. Three doses of 1 ml. intramuscularly arrested the skin irritation, and he has remained free from any sort of this trouble to date, although still working daily with diesel oil. The second patient was a cook, aged 45. She was said to have had soap dermatitis for the past six months; arms and wrists affected, also neck. Prescription of soap, etc., had little effect. Again three doses of manganese, 1 ml., intramuscularly completely arrested this form of skin irritation. A routine examination of all the systems was made in each case and, seen recently, both have remained well.

Screening Aid for Mass Radiography

Dr. R. TREHARNE JAMES (Reading) writes: I was interested to read the description of a daylight screening aid for mass radiography units by Dr. S. W. Vivian Davies (Dec. 25, 1948, p. 1117). We have encountered the same difficulties as his unit in darkening our working sites and have for some months been using a similar screening hood. Though it is extremely useful it has one drawback. I think, in that the radiographer and his assistants are excluded from viewing the appearances. Time does not permit the examination to be repeated by several persons, nor does radiation dosage. Also it is desirable that the hood be removable easily and rapidly for laundering.

Obituary

STANLEY RAW, M.D., F.R.C.S.Ed.

Stanley Raw, who died with tragic suddenness at the age of 70 on Dec. 26, 1948, was one of the outstanding surgeons in the North of England. He was a student at the University of Durham, and he graduated M.B., B.S. in 1901. He proceeded M.D. in 1903, and took the F.R.C.S.Ed. in 1905. Raw was senior resident medical officer at the Sunderland Infirmary before starting in general practice in that town. He was later elected surgeon to the Children's Hospital. In 1915 he joined the R.A.M.C. and was surgeon to the Liverpool Merchants' Hospital, and spent some years in France. On his return he was appointed surgeon to the Royal Infirmary, Sunderland, and he gave up general practice. He also became surgeon to the Sunderland General Hospital. In 1931 the Durham colliery owners asked Mr. Raw to become medical officer to some of their groups. In 1945 he reached the retiring age and became consulting surgeon to the Royal Infirmary and to the General Hospital, but continued with his other work. He was chairman of the Sunderland Division of the B.M.A. in 1924-6 and a former president of the Northern Counties Clinical Society.

Raw was an accomplished surgeon with a leaning towards gynaecology. His results were good, and his surgical opinion was eagerly and widely sought. No one had more thought for the welfare of his patients, and his daily morning and evening rounds continued to the end. As a colliery medical officer, although there may have been disagreements from time to time, no pitman ever doubted his fairness, though sometimes his task was difficult. Raw's great interest was in the Royal Infirmary, Sunderland, and at endless discussions and innumerable committee meetings he did everything he could to advance its scope and improve its facilities. His ideas of hospital administration were much ahead of his time, and the Royal Infirmary, with which he was associated for forty-seven years, owes him an enormous debt. From 1930 to 1943 he was chairman of the medical board of the Infirmary. Sometimes a difference of opinion might become a personal disagreement and lead to temporary estrangement, but Raw himself had had some disappointments in earlier professional life.

He had climbed mountains, sailed small boats, and was golfing to the last. He was always advocating travel. Personally he was acute, astute, a wise counsellor, and a good companion. Being without children, he was most attached to his nephews and took great pride in their achievements. To those he was interested in or liked he was generosity itself. In his own world he was a very considerable figure; with some change of fortune he might have been much more widely known. Stanley was a personality with an English character; latterly he was an institution with a touch of magnificence. To his widow, who was his companion and helpmate for so many years, the sympathy of all his colleagues will be extended.—P.A.

H. L. Duke writes: As an Englishman who was privileged to enjoy close personal association with van Hoof during the fifteen months' sojourn in Uganda of the League of Nations Sleeping Sickness Commission, I should like to add a brief tribute to your account (Jan. 1, p. 34) of the personality of a very charming colleague. Van Hoof was a first-rate mixer, at home with all and sundry, high or low, black or white, peaceful or obstreperous. As a host he was ideal; an admirable raconteur, genial, with an acute sense of humour and a temperament imperturbable and placid. He loved a joke, practical or otherwise. He had a wonderful way with the natives, and his staff worshipped him and rendered him unquestioning loyalty. He knew all about a motor-car, and was a truly invaluable companion on the long empty stretches of the tsetse country in which the Commission spent so much time. His English was excellent, and his knowledge of human nature apparently inexhaustible. Yet one felt in those days that his main concern was his scientific work, and he was always ready at a moment's notice to switch off into a serious discussion of the programme. A gallant gentleman and a sad loss to his many friends.

Dr. JAMES RUST died at Malvern on Dec. 10, 1948, at the age of 79. After completing his early education at the Aberdeen Grammar School, he took his M.A. degree as a student of Aberdeen University in 1889, graduating M.B., C.M. in 1892, and proceeding M.D. in 1895. He was house-surgeon to the late Sir Alexander Ogston before taking up an appointment in China. Returning to England, he bought a practice in Gt. Colmore Street, Birmingham, where he remained until his retirement about ten years ago. Before his retirement he had been operated on for pyloric stenosis; he recovered from this operation and enjoyed fairly good health until last year, when signs of heart failure preceded his death from coronary thrombosis. Dr. Rust was a kind and generous friend, well loved by everyone, and he will be greatly missed. He was medical officer to the V.A.D. Auxiliary Hospital in Birmingham from May, 1915, to December, 1916, and was also divisional surgeon of the St. John Ambulance Brigade. He was a member of the panel committee for several years, and also prime mover in the formation of the Aberdeen University Club for Birmingham and the Midlands, of which he became the first president. He presented a silver cup to be competed for by the golfing members of the club. Dr. Rust, who was unmarried, never really recovered from the death of his sister, who was devoted to him.—A. H. M.

Dr. ALEXANDER BROWN JAMIESON, who since 1919 had been a member of the tuberculosis service of the Lancashire County Council, died suddenly at his home in Great Ecclestone, Lancs, on Dec. 16, 1948. Dr. Jamieson graduated M.B., Ch.B. at Edinburgh University in 1910. For many years he worked in the districts served by dispensaries at Eccles, Leigh, Stretford, Farnworth, and Pendlebury, and also at the Peel Hall Pulmonary Hospital, Little Hulton. In February, 1945, he was appointed a member of the senior staff and became medical superintendent of the Elswick Sanatorium, near Kirkham, and consultant tuberculosis officer for the Fylde dispensary area. Recently the Manchester Regional Hospital Board established an enlarged dispensary area, bringing in Blackpool County Borough, and Dr. Jamieson became the chest physician of the Victoria Hospital in that town. Dr. Jamieson leaves a widow and one son. He was of a quiet disposition and was universally liked by his colleagues of the medical, nursing, and clerical staffs.

Medico-Legal

DURATION OF AGGRAVATION

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A soldier contracted bronchitis while serving in the Army before the war. He was passed fit for service in 1939 and was put on guard duties which exposed him to the weather. In January, 1940, he became ill with influenza and a specialist reported that he was suffering from chronic bronchitis. For the next two years he was constantly on the sick list, and he was discharged in May, 1942. Seven months later a medical board found that his working capacity was reduced owing to shortness of breath. In 1944 his claim for a pension was rejected by a pensions appeal tribunal. In 1947 it was again rejected by a special tribunal which found that he had been in the Army for nearly three years, during which he was subject to no conditions which could be supposed to have exercised any influence on his bronchitis. He appealed to the court, and Mr. Justice Denning¹ held that the finding of the tribunals could not be reconciled with the evidence, and that the only reasonable conclusion was that at the date of the appellant's discharge his complaint had been aggravated by war service.

The question was raised whether the aggravation due to war service had not passed away, and whether a tribunal making such an award could say for how long the aggravation had continued, and if and when it had passed away. His lordship thought a tribunal could do so, provided that both parties had notice that the point was to be considered. A claim made immediately on discharge, he said, took some time to reach a pensions appeal tribunal, and the claimant usually pleaded not only that the disease was aggravated at the date of discharge but also that it remained aggravated at the date of the hearing. When the Minister rejected such a claim, he said that the

BURROUGHS WELLCOME & CO. (The Wellcome Foundation Ltd.) LONDON

THE PROBLEM OF
Seborrhæic
affections

CHRONIC skin diseases such as acne, seborrhœa
oleosa, and rosacea are very distressing to the
patient. In the case of women it is particularly difficult
to treat facial lesions without further disfigurement.

Genatosan Products offer two happy solutions to the
problem. Dermatological Cream No. 10 (Zinc. Sulph.
3%, Potass. Sulphurat. 3%) contains the active in-

gredients in a non-greasy base. For day use the cream
may be employed as a powder base without detracting
from its therapeutic value, and your patients will
appreciate the lack of restriction on the use of cosmetics.

Alternatively, or additionally 'Fissan' Ichthammol
Powder (2% Ichthammol) is flesh tinted and can be used
as a face powder.

Information and literature upon request to the Medical Department.

For chilblains
'PERNIVIT'

Tablets of Acetomenaphthone
and Nicotinic Acid B.D.H.

Considerable success in the treatment of chilblains has been reported following the use of acetomenaphthone in one group of patients and of nicotinic acid in a second group.

It may be that abnormal venous permeability and prolonged blood clotting time on the one hand and venous stasis from vasoconstriction on the other are both contributory causes of chilblains.

Trial of a combination of acetomenaphthone and nicotinic acid collaterally, therefore, seems justified. 'Pernivit' is now available as tablets, each containing

Acetomenaphthone 7 mg.
(Prokayvit Oral)

Nicotinic Acid 25 mg.
Bottles of 50 and 500 tablets

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Jan. 1.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available

* Measles and whooping cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county) will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county) and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Influenza

Deaths certified as due to influenza in the 126 great towns rose to 47 in the week ended Jan. 8, compared with 29 in the previous week. This is the largest weekly total since the spring of 1947. The rise is not disproportionate for the season and suggests that virus influenza had not reached epidemic proportions in England and Wales. There is, however, confirmation that influenza has spread across Europe from the south-east. The disease appeared in Italy early in December, 1948, and had crossed to the Haute-Savoie about Dec. 15. It spread up the eastern border of France between Dec. 15 and Dec. 20 and affected most of the country, sparing only a few departments. It seems that it was not present in Paris until about Dec. 20, and the attack rate increased about Christmas. In Paris it took about fourteen days for the disease to reach a maximum incidence. There is, so far, no sign of regression. A conservative estimate of incidence up to the present is 15% of the population of France. Some communities have experienced attack rates up to 30 or even 40%.

The spread to the Northern European countries continues. In Holland the disease entered at Eindhoven on Dec. 31 and appeared in Leiden seven days later. Outside France and Italy, according to telegraphic reports received in Geneva up to Jan. 11, there had been no abnormal increase in influenza in Scandinavia, Spain, Hungary, and the American zone of Germany. The disease was prevalent in the Vorarlberg Tyrol of Austria. In Switzerland thirteen cantons were affected, particularly Tessin, Geneva, and Basle. To the east there were small foci in certain towns in Turkey, but no epidemic. In Northern Europe the epidemic was still confined to South Holland.

Clinical Features.—The disease occurring in France is typical and easily distinguished from the benign seasonal catarrhs. The average case has an abrupt onset with headache, weakness, muscle pains, and fever. Apart from a sore throat, signs referable to the respiratory system are few at onset. In the ordinary case the illness lasts seven days and is followed by some debility. Complications are few and encephalitis has not been reported. Pulmonary complications have killed elderly people. A few deaths from acute pulmonary oedema in the first thirty-six hours of the illness, particularly in children under 2, have been mentioned.

Virus.—In a previous announcement "virus B" was mentioned. It now seems more probable that the virus mainly responsible is more closely related to virus A. Identification experiments at the World Influenza Centre laboratory at Hampstead are incomplete.

Local Health Authorities.—The Ministry of Health has advised local authorities in England and Wales that the increased incidence of influenza in parts of Europe may foreshadow an early outbreak in this country, although there are no signs of this at present. It is suggested that medical officers of health and local authorities should plan in advance the arrangements which may have to be made if there is an unusually heavy incidence of influenza. These measures will be related to the local health authorities' services under Part III of the National Health Service Act, and the home nursing and domestic help services may both have to meet considerable extra demands. In a circular issued recently the Ministry urges that at the moment local health authorities should do no more than shape precautionary plans against the possibility of a large-scale outbreak.

Annual Report of England and Wales for 1946

The crude death rate during 1946 was 12.0 per 1,000, but when corrected for age the Comparative Mortality Index was 0.881 and was the lowest value yet recorded. Infant mortality was 42.85 per 1,000 live births and was the lowest value ever recorded. The neonatal mortality of 24.46 was 0.30 below the value for 1945 and 0.11 above the value for 1944. Maternal mortality decreased from the previous lowest level of 1.47 in 1945 to 1.24 per 1,000 total births. The death rates per million children under the age of 15 were 40 for diphtheria, 3 for scarlet fever, and 22 for measles, and were the lowest rates ever recorded; the rate for whooping-cough was 91, an increase of 12 on the 1945 rate but appreciably lower than the pre-war average.

Discussion of Table

In England and Wales during the week under review there were increases in the notifications of measles 2,162, acute pneumonia 258, whooping-cough 224, diphtheria 42, and dysentery 23. The only decrease was in the incidence of scarlet fever 29.

The largest increases in the notifications of measles were Lancashire 484, London 184, Staffordshire 157, Cheshire 146, Somerset 117, and Berkshire 116. The largest changes in the incidence of whooping-cough were increases in Lancashire 96

and Warwickshire 52, and a decrease in Glamorganshire 50. There was an increase of 12 in the incidence of diphtheria in London. Little change was recorded in the local incidence of scarlet fever. A rise in the notifications of acute pneumonia occurred in every region of the country.

The largest returns of dysentery were Lancashire 12 (Liverpool C.B. 7) and London 9 (Hackney 7). Two of the 3 cases of paratyphoid fever and 4 of the 7 cases of typhoid fever were notified in Lancashire. Only two counties had more than one notification of acute poliomyelitis: Worcestershire 4 (Kidderminster M.B. 3) and Derbyshire 2, both notified in Whaley Bridge U.D.

In Scotland there were decreases in the notifications of whooping-cough 80 and measles 45, while rises were reported for acute primary pneumonia 36 and dysentery 11. A small increase in the incidence of dysentery was recorded in all except the northern areas. The rise in the incidence of pneumonia occurred mainly in the north-eastern and eastern area.

In Eire increases of 52 in the notifications of measles and of 31 in the notifications of pneumonia were the only changes of note. The largest outbreak of measles was at Laoighis, Athy No. 2 R.D. 32.

In Northern Ireland a fall from 11 to 2 in the notifications of diphtheria was the chief feature of the returns.

Quarterly Returns for Northern Ireland

The birth rate for the September quarter was 21.5 per 1,000 and was 1.3 below the average for the third quarters for the preceding five years. Infant mortality was 41 per 1,000 registered births and was 12 below the five years' average. The general death rate was 9.9 per 1,000 and was 0.4 below the average for the five third quarters. Deaths attributed to the principal infectious diseases numbered 56 and included 26 from infantile diarrhoea and enteritis, 14 from measles, and 10 from whooping-cough. No deaths were due to diphtheria. Deaths from pulmonary tuberculosis numbered 166 and from other forms of tuberculosis 48; these totals were 14 and 9 respectively below the averages of the five preceding quarters.

Week Ending January 8

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,022, whooping-cough 2,306, diphtheria 126, measles 13,185, acute pneumonia 1,181, cerebrospinal fever 43, acute poliomyelitis 19, dysentery 81, paratyphoid 2, and typhoid 4.

Medical News

Dr. Anne Gibson Survives Air-crash

On the basis of information in the daily press we announced last week the "death" on Jan. 5, 1949, as the result of an air crash, of Dr. Anne Gibson, of St. James's Hospital, Balham, S.W.12. Happily Dr. Gibson survived the disaster. We much regret the error and any distress the announcement may have caused Dr. Gibson, her relatives, and her friends. Dr. Gibson was a passenger in an airliner which crashed in Brazil while on its way to Chile. The medical superintendent of St. James's Hospital informs us that a message has recently been received from Dr. Anne Gibson stating that she is alive and well.

King Edward's Hospital Fund

His Majesty the King has sent an annual subscription of £1,000 for 1949 to King Edward's Hospital Fund for London. The Fund has also received a further instalment of £150,000 from the Nuffield Trust for the Special Areas. In founding this Trust Lord Nuffield provided that any sums that might be available by way of repayment of loans or otherwise from his Trust for the Special Areas should pass to King Edward's Hospital Fund for London. A total sum of £1,150,000 has now been received.

Prospective Parliamentary Candidate

Dr. A. D. D. Broughton has been chosen by Batley and Morley Labour Party (Yorks) as prospective candidate in the by-election caused by the death of Captain Beaumont. In 1945 Captain Beaumont had a majority for the Socialist Party of 11,592.

London County Medical Society

At the annual general meeting of the London County Medical Society on Jan. 5 the following officers were elected: president, Dr. C. D. Coyle; vice-president, Mr. Iain Matheson; hon. treasurer, Dr. L. T. Hilliard; hon. secretary, Mr. J. Gabe. A full programme for the forthcoming year is being arranged. The next meeting of the Society will be held on Thursday, Feb. 3, at 4.30 p.m. at

Mile End Hospital, Bancroft Road, E.1. Dr. A. F. Mohun and Dr. J. Rubie will open a discussion on streptomycin in the treatment of tuberculosis. The annual subscription of five shillings is now due and should be sent to Dr. L. T. Hilliard, the Fountain Hospital, S.W.17. Membership is open to any medical practitioner. Inquiries should be addressed to Mr. J. Gabe, F.R.C.S., St. Alfege's Hospital, Vanbrugh Hill, S.E.10.

French Award

The French Government has recently conferred the Médaille de la Reconnaissance Française on the following: Lord Moran, P.R.C.P., Dr. K. E. Eckenstein, Dr. N. M. Goodman, Dr. Dorothy Gough, Mr. Holmes Sellors, Dr. L. E. Houghton, Dr. J. Moore, Dr. A. J. Morland, Dr. Eugene Nassau, Dr. P. G. Stock, Dr. R. E. Stuart-Webb.

COMING EVENTS

National Health Service Act

Dr. Charles Hill, Secretary of the Association, will address a meeting of members of the Metropolitan Counties Branch on Thursday, Jan. 27, at 8 p.m., in the Great Hall, B.M.A. House, Tavistock Square, London, W.C. The title of the address will be, "Terms of Service."

Guild of St. Luke, SS. Cosmas and Damian

A dinner-dance organized by the Westminster Branch of the Guild of St. Luke, SS. Cosmas and Damian will be held at Dorchester Hotel, Park Lane, London, W., on Thursday, Feb. 3, at 7.30 p.m., when guests will be received by His Eminence Cardinal Griffin. Tickets (£1 11s. 6d. each) may be obtained from the honorary secretary, 5, Wimpole Street, London, W.1 (Tel.: Langham 3230).

Edinburgh Lectures

A series of Honyman Gillespie Lectures has been arranged, in association with the Edinburgh Postgraduate Courses, to take place during the spring term in the West Medical Theatre of Edinburgh Royal Infirmary on Thursdays, Feb. 10, 17, and 24, at 5 p.m. The lectures are open to all graduates and senior students. Details will be published in the diary columns of the *Journal* week by week.

Public Health and Hygiene

The Royal Institute of Public Health and Hygiene announces that the next course of instruction for the Certificate in Public Health and for the Diploma in Industrial Health (Part I) will commence on March 25. Prospectuses, enrolment forms, and full details may be obtained from the secretary of the Institute, 28, Portland Place, London, W.1.

Banting Memorial Lecture

Professor John Beattie, Bernhard Baron Research Professor at the Royal College of Surgeons of England, will deliver the Banting Memorial Lecture at Toronto next month.

Rheumatic Diseases Conference

The 7th International Congress on Rheumatic Diseases will be held in New York City on May 30-June 3 under the auspices of the International League against Rheumatism (*Journal*, Dec. 4, 1948, p. 1003). The date by which information on the presentation or discussion of papers is requested has been extended to Feb. 15. Information may be obtained from Dr. Ralph Pemberton, 1901, Walnut Street, Philadelphia, Pennsylvania, U.S.A.

Congress of Life Assurance Medicine

The Third International Congress of Life Assurance Medicine will be held in Rome on June 6-9. The titles of the subjects for discussion and the names of the opening speakers are as follows: "Medical Examination on Life Assurance—Its Difficulties and Pitfalls": Professor H. Courcoux (Paris), Dr. R. de Beden (Trieste). "The Influence of Heredity on Mortality": Professor R. Sand (Brussels), Professor V. Bisceglie (Catania). "Heart Disease and Life Assurance"—(a) "Valvular Defects": Dr. H. D. E. Milders (Rotterdam), Dr. Terence East (London); (b) "The Arrhythmias": Dr. J. R. B. Hutchinson (Washington), Dr. V. Mortensen (Copenhagen). "The Lessons of the War in Relation to Preventive Medicine": Professor Ch. Richet (Paris), Dr. F. Kaufman (Zurich), Professor G. Mazzetti (Florence), Dr. A. Starna (Rome). All doctors interested in life assurance medicine are entitled to attend, and any wishing to take part in the discussions should communicate with the secretary of the Congress at Piazza San Bernardo 101, Rome, not later than the end of March, 1949, sending a summary of their communication, which should not exceed 200 lines and which should be accompanied if possible by translations in French, German, and Italian, the three official languages of the Congress. Information about travelling arrangements and accommodation can be obtained from the secretary of the Life Assurance Medical Society—Dr. Kenneth Dickson, 3, Lombard Street, E.C.3.

SOCIETIES AND LECTURES

Saturday

SOUTH EAST METROPOLITAN REGIONAL TUBERCULOSIS SOCIETY.—At Preston Hall, Aylesford, Kent, Jan. 22, 10.30 a.m. General meeting.

Monday

UNIVERSITY COLLEGE LONDON.—At Physiology Theatre, Gower Street, London, W.C., Jan. 24, 4.45 p.m. "The Ultracentrifuge and Electrophoresis Apparatus in Protein Research," by Dr P. Johnson, Ph.D.

Tuesday

EUGENICS SOCIETY.—At Royal Society, Burlington House, Piccadilly London, W., Jan. 25, 5.30 p.m. "The Work of the Galton Laboratory," by Professor L. S. Penrose.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Jan. 25, 5 p.m. "Histopathology of the Skin," by Dr. I. Muende.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Jan. 25, 11 a.m. "Infections of Urogenital Tract Due to *Candida Albicans*," by Dr. W. N. Mascall.

UNIVERSITY COLLEGE LONDON.—At Physiology Theatre, Gower Street, London, W.C., Jan. 25, 5.15 p.m. "Respiration," by Dr. E. A. Underwood.

Wednesday

BRITISH ASSOCIATION OF PHYSICAL MEDICINE.—At St. Thomas's Hospital, London, S.E., Jan. 26, 5.30 p.m. "How to Examine a Joint." Demonstration by Dr. J. H. Cyriax.

INSTITUTE OF PSYCHIATRY (UNIVERSITY OF LONDON).—At Maudsley Hospital, Denmark Hill, London, S.E., Jan. 26, 2.45 p.m. "The *Thalamus*," by Professor W. E. Le Gros Clark.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Jan. 26, 11 a.m. "Ocular Manifestations of Venereal Disease," by Dr. A. H. Harkness.

LONDON UNIVERSITY.—At School of Pharmacy, 17, Bloomsbury Square, London, W.C., Jan. 26, 5.30 p.m. "The Use of Radio-active Tracers in Biological Research," by Professor F. A. Paneth, F.R.S.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, 242, St Vincent Street, Glasgow.—Jan. 26, 5 p.m. "Some Aspects of the Surgery of the Spleen," by Professor J. R. Learmonth.

Thursday

DEWSBURY: STAINCLIFFE GENERAL HOSPITAL.—Jan. 27, 9 p.m. "Clinical Problems in the Diagnosis and Treatment of Thyroid Disease" by Professor R. E. Tunbridge.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Jan. 27, 11 a.m. "Chancroid," by Dr. W. N. Mascall.

LONDON UNIVERSITY.—At School of Pharmacy, 17, Bloomsbury Square, London, W.C., Jan. 27, 5.30 p.m. "The Use of Radio-active Tracers in Biological Research," by Professor F. A. Paneth, F.R.S.

MEDICO-LEGAL SOCIETY.—At 26, Portland Place, London, W., Jan. 27, 8.15 p.m. "The Coroner, the Doctor, and the Public," by Robert Forbes.

ROYAL SANITARY INSTITUTE.—At Town Hall, Wolverhampton, Jan. 27, 10.15 a.m. Discussions. "The Present Housing Problem—Is New Legislation Necessary?" to be opened by Mr. F. B. Hartley. "The Scope of Care Work and Who Should Undertake It," to be opened by Dr. G. Ramage.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—At Large Lecture Theatre, Jan. 27, 4.30 p.m. Lecture demonstration. "Neurology."

UNIVERSITY COLLEGE LONDON.—At Anatomy Theatre, Gower Street, London, W.C., Jan. 27, 1.15 p.m. "Some Modern Views on Evolution," by Professor J. B. S. Haldane.

Friday

KENT AND CANTERBURY HOSPITAL, Canterbury.—Jan. 28, 5 p.m. to 7 p.m. Clinical meeting.

LONDON CHEST HOSPITAL, Victoria Park, E.—Jan. 28, 5 p.m. "Extrathoracic Pain in Cardiovascular Disease," by Dr. J. L. Lovibond.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, London, W.—Jan. 28, 8 p.m. General meeting. "Modern Interpretations of Serum Tests," by Dr. I. N. Orpwood Price.

NORTH OF ENGLAND SOCIETY OF ANAESTHETISTS.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Jan. 28, 7.30 p.m. Third meeting. "Dental Anaesthesia," by Dr. Bernard Johnson.

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—Jan. 28, 8 p.m. Debate.

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHARMACOLOGY.—At Physiology Theatre, Gower Street, London, W.C., Jan. 28, 5.15 p.m. "The Relationship Between Physico-chemical Properties of Drugs and Their Pharmacological Activities," by Dr. F. Bergel, Ph.D.

Saturday

NORTH OF ENGLAND OTOLARYNGOLOGICAL SOCIETY.—At Eye and Ear Infirmary, Myrtle Street, Liverpool, Jan. 29, 2 p.m. Clinical meeting.

APPOINTMENTS

CASSON, F. R. C., M.B., D.P.M., Clinical Assistant, Department of Psychological Medicine, King's College Hospital, Denmark Hill, London, S.E.
COWAN, KENNETH, M.D., D.P.H., County Medical Officer and School Medical Officer for Essex.

FOGARTY, T. N., M.B., B.Ch., D.M.R.E., Consultant Radiologist, Lurgan Banbridge, Portadown, Dungannon, and Armagh City Hospitals.

FRASER, JOHN, M.B., Ch.B., Medical Superintendent Edinburgh Convalescent Hospitals Group, Scottish South-Eastern Regional Hospital Board.

HARVEY, F. C. B., M.R.C.S., L.R.C.P., Full-time Medical Officer of Health for District No. 9 (including Abergavenny Borough and Rural areas), Wels Board of Health.

HILDITCH, J. HAWORTH, M.B., Ch.B., D.P.H., Medical Officer for Wigan.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.—House physicians, M. G. Philpott, M.B., B.S., M.R.C.P., H. J. W. Fisher, M.B., B.S., M.R.C.P., House-surgeon, M. E. Larg, M.R.C.S., L.R.C.P., D.R.C.O.G., Medical Registrar and Pathologist, S. D. V. Weller, M.D., M.R.C.P. Registrar to the Department of Psychological Medicine, R. Meyer, M.B., B.Ch., M.R.C.P.

HURFORD, J. V., M.D., M.R.C.P., D.P.H., Physician-Superintendent, King George V Sanatorium, Godalming, Surrey.

LONGBOTTOM, DONALD, M.B., Ch.B., D.P.H., Divisional Medical Officer and Medical Officer of Health to the Altrincham Division Cheshire County Council.

OWEN, EVELYN D., M.B., B.S., D.P.H., Full-time Medical Officer for Cwmbran and Caerleon Urban Districts (Area No. 8), Monmouthshire.

SILVERTON, M. I., M.R.C.S., L.R.C.P., Medical Officer of Health, Battul Rural District, Sussex.

SOUTH-WESTERN REGIONAL HOSPITAL BOARD.—The following appointments are announced: J. A. Pitt Evans, M.B., B.S., Pathologist, Cheltenham General Hospital; N. R. W. Simpson, M.B., B.S., Director of Physiotherapy, North Gloucestershire Group of Hospitals.

TATTERSALL, P. E. R., M.D., M.R.C.P., Physician, Tyrone County Hospital, Omagh, under Northern Ireland Health Service.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Lee.—On Jan 7, 1949, at Liverpool Maternity Hospital, to Hazel (née Green) wife of Dr. David Lee, 1, Storr'sdale Road, Liverpool, a son.

Mansour.—On Jan 4, 1949, at Liverpool Maternity Hospital, to Enid Eilee (née Huston), wife of Dr. Joseph Mansour, a son.

O'Hagan.—On Dec 23, 1948, to Dorothy (née Pledge, M.B., B.S.), wife of Stanley A. O'Hagan, M.B., B.S., D.P.H., of Winterringham, Scunthorpe a son—Michael Stanley.

Ritchie.—On Jan 13, 1949, at Edinburgh, to Professor Anthony and Dr. Elizabeth Ritchie, University of St. Andrews, a son.

Rosser.—On Dec 25, 1948, at the Birmingham Maternity Hospital, to Peggy (née Dash, M.B., B.S.), wife of Brinley M. Rosser, a son.

DEATHS

Bainbridge.—On Jan 8, 1949, suddenly, Dr. Matthew McLintock Bainbridge of 316, Monument Road, Birmingham. Dearly loved husband of Eva and second son of the late Reverend Philip and Mrs. Bainbridge, of Makerstoun Kelso.

Barker.—On Jan 11, 1949, at 3, Randolph Place, Edinburgh, Duncan McFarlan Barker, M.B., Ch.B.

Blake.—On Jan 10, 1949, at 6, Regent Road, Great Yarmouth, Valentine Henry Blake, M.B., B.S.

Denmark.—On Jan 10, 1949, Alexander George Denmark, M.D., of Burleigh Bishopsteignton, Devon.

Foggie.—On Jan 13, 1949, at Dundee Royal Infirmary, William Edward Foggie, D.S.O., M.D., F.R.C.P.Ed.

Graham.—On Jan 2, 1949, Thomas Graham, M.C., M.B., Ch.B., of 46, Cranston Avenue, Bexhill, aged 72.

Grant.—On Jan 11, 1949 John Wemyss Grant, M.B., C.M., D.P.H., Lieutenant Colonel, I.M.S., retired of 29, Carlton Avenue, Broadstairs, Kent, aged 79.

Hewitt.—On Dec 28, 1948 at Canford Lane, Bristol, John Hewitt, L.R.C.P.&S.I. and L.M., of Clevedon Road, Weston-super-Mare, aged 73.

Hodgson.—On Jan 2, 1949, at 162, Northway, Maghull, Liverpool, Albert Ernest Hodgson, M.D., D.P.H., aged 68.

Holthouse.—On Jan 2, 1949, Edwin Hermus Holthouse, F.R.C.S., of 6, Gilbert Road, Ramsgate, formerly of 1, Park Crescent, London W., aged 93.

Hutchinson.—On Jan 11, 1949, at Bournemouth, Leslie Thomson Ross Hutchinson, M.D., D.P.H., Lieutenant-Colonel, I.M.S., retired.

Leach.—On Jan. 9, 1949, at Royal Northern Infirmary, Inverness, William John Leach, M.B., Ch.B., of Eileandonan, Beaully, Inverness-shire.

Lees.—On Jan 10, 1949, Edwin Leonard Lees, M.D., of Clifton, Bristol, aged 85.

MacLaren.—On Jan 6, 1949, at 10, Scarsdale Villas, London, W., James Alexander MacLaren, M.B., C.M.Ed., aged 89.

Messer.—On Jan 1, 1949 Andrew William Messer, M.B., C.M.Ed., J.P., of Lemington-on-Tyne, Northumberland, aged 82.

Nicol.—On Jan 7, 1949, at a Bournemouth nursing home, Alexander Campbell Nicol, M.R.C.S., L.R.C.P., formerly of Springfield Crescent, Parkstone, Dorset, aged 76.

Rees.—On Nov 21, 1948, Thomas Rogers Rees, M.R.C.S., L.R.C.P., of Cardiff, aged 56.

Russell-Cargill.—On Jan 7, 1949, at 162, Ashley Gardens, London, S.W., James Alexander Russell-Cargill, M.B., Ch.B.Ed.

Rust.—On Dec 10, 1948, at Graham Road, Malvern, Worcs, James Rust, M.D., aged 79.

Sadlier.—On Jan 5, 1949, at Masterton, New Zealand, Horace William Sadlier, M.B., B.Ch.

Sands.—On Jan 6, 1949, at his home, Gringley-on-the-Hill, Doncaster, Howard Sands, M.B., B.Ch., late of Chapelton, Sheffield, aged 83.

Watt.—On Jan 2, 1949, at Perth Royal Infirmary, John Watt, L.R.C.P.&S.Ed., I.D.S., of St. Margarets, Muthill, Perthshire, eldest son of the late J. W. J. Watt, Glasgow.

Wild.—On Jan 6, 1949, at New End Hospital, London N.W., Granville Burnett Wild, M.B., Ch.B., Lieutenant-Colonel, R.A.M.C., aged 57.

HANDS AND THE MAN . . . NO. 5

Mr., Thoracic Surgeon

PNEUMONECTOMY. In these skilful hands is the excised lung under post-operative scrutiny with the carcinoma clearly exposed. A thoracic operation demanding from the surgeon exceptional courage and dexterity, during which he can rely upon ligatures and sutures only of the highest integrity. Ethicon sutures are the continual and specialised concern of the largest organisation of its kind in the world. Every Ethicon suture sold in the United Kingdom is of British manufacture.

All orders for Ethicon and Ethicon Measurements should be sent to your usual wholesaler

MEYERSONS (SUTURES) LTD
ST. JOHN'S HILL · EDINBURGH · SCOTLAND

An effective new antidote for ARSENIC, MERCURY & GOLD POISONING

Originally introduced during the war for the treatment of Lewisite gas poisoning, B.A.L. has now been applied to the treatment of poisoning by other arsenical compounds as well as mercury and gold salts.

Injection of B.A.L. consists of a sterile 5 per cent. solution of 2, 3-Dimercaptopropanol in arachis oil containing 10% Benzyl Benzoate. Supplied in boxes of 12 x 2 c.cm. ampoules.

B.A.L

(BRITISH ANTI-LEWISITE)

Further information gladly sent on request to

For early control of urinary infections

'Mandamine' is a valuable urinary antiseptic which combines the well-established antibacterial actions of mandelic acid and methenamine in one chemical compound. The tablets are effective against a wide range of organisms encountered in urinary infections and are indicated in: cystitis, prostatitis, pyelonephritis, and infections accompanying renal calculi and neurogenic bladder. Its safety and facility of therapy make 'Mandamine' especially suitable for administration during pregnancy, to children, and in stubborn cases where treatment is necessarily prolonged.

Each enteric-coated tablet contains 0.25 g. (3½ gr.) methenamine mandelate

Samples and literature on request

MENLEY & JAMES, LTD.
123 Coldharbour Lane, London, S.E.5

5 ADVANTAGES OF 'MANDAMINE'

1. Virtual freedom from side-effects
2. Wide range of bactericidal effectiveness
3. No supplementary acidification is required
4. No dietary control or restriction of fluid intake is necessary
5. Early control of the infection is the characteristic response

'Mandamine' is the registered trade mark of Nepera Chemical Co. Inc., New York, to designate its brand of methenamine mandelate

'PALUDRINE'

TRADE MARK

The New Antimalarial

Extensive clinical investigations have established that 'Paludrine' is a highly efficient antimalarial with important advantages over mepacrine and quinine.

- 'Paludrine' controls the clinical symptoms of all forms of malaria and terminates the attack.
- 'Paludrine' is a true causal prophylactic in malignant tertian malaria and a partial causal prophylactic in benign tertian malaria.
- It produces radical cures in malignant tertian malaria and controls relapses in benign tertian malaria indefinitely on a twice-weekly dosage.
- 'Paludrine' is a colourless drug and in normal dosage does not produce unpleasant symptoms of any kind.

Tablets of 0.1 gramme (containers of 30, 100 and 1,000). Tablets of 0.025 gramme (containers of 20 and 500). Solution: Ampoules of 2 c.c. containing 0.1 gramme as 5% solution. Boxes of 5 and 25.

Literature on request.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Home-cured Tobacco and Amblyopia

Q.—Is there any evidence to support the suggestion that the smoking of home-cured tobacco may lead to tobacco amblyopia more readily than the smoking of tobacco cured commercially?

A.—Before any attempt is made to guess at the possible results of the use of home-cured tobacco, it may be as well to consider the factors generally accepted as leading to tobacco amblyopia. This is due to a breakdown in tolerance to nicotine and occurs when the intake of toxic substances exceeds the capacity of the liver to deal with them. The problem concerns the functions of the liver, and especially its formation of glycogen, in addition to the local reaction in the eye. Schepens was able to observe a large number of cases in Belgium during the recent war (*Trans. ophthalm. Soc. U.K.*, 1946, 66, 309). He found that tobacco amblyopia, a rarity before the war, had increased about ten times. Several factors must be considered in each case—type of tobacco, alcohol consumption, food deficiency, and mental strain.

Tobacco as sold commercially has a small nicotine content owing to the breakdown of that substance by fermentation during the process of curing. In "green" tobacco the fermentation has not been completed and the percentage of nicotine is high. The stalks and ribs are more toxic than the leaf, and so, if they are not to be removed, they must be well crushed and broken up to allow of better fermentation. It was found in Belgium during the war that a poor quality of tobacco, as judged by the smoker, need not be as toxic as an apparently better tobacco. It was also found that the home-grown leaf was responsible for more cases of amblyopia than the commercial brands. In the past it has been taught that a high consumption of alcohol, especially spirits, predisposes to amblyopia. The pendulum is now swinging in the opposite direction, and many assert that alcohol has little or no influence in making the eyes more susceptible. Food deficiencies, especially in proteins and fats, are definitely in the picture. Many cases of amblyopia were seen by Dr. Wecker in the Siege of Paris in 1870, and the numbers were found to be increased in Germany after the 1914-18 war. With such deficiencies recovery is slower and sometimes minor lesions are to be detected in the fundus. Despite the prominent position of vitamins in the dietary, a reduced intake probably has no influence at all on the occurrence of tobacco amblyopia. Mental strain seems to increase susceptibility to the disease, and this was obviously present during the Siege of Paris, in Germany during the war of 1914-18, and in Belgium in the last war. It may have an effect *per se*, or lead to a greater consumption of tobacco in order "to soothe the nerves" and allay hunger.

Amblyopia is most prevalent between the ages of 55 and 60, but under the adverse conditions listed above cases have been recorded at 30. The lesion is now considered to be primarily in the retina itself, the optic nerve being only secondarily affected at a late stage. Cure of the condition usually confers immunity, and recurrence is rare. To sum up, home-grown tobacco need not be toxic and produce tobacco amblyopia if it is properly fermented and cured before use. The danger, however, is greatly enhanced if there is any dietary deficiency or excessive mental strain.

Threatened Abortion

Q.—(a) Has progesterone any place in the treatment of threatened abortion in the absence of facilities for a pregnanediol excretion test? (b) Please recommend the routine most likely to be successful in preventing abortion when a woman, three months pregnant and with no apparent abnormality, starts to bleed.

A.—(a) There is still some dispute, but the evidence so far available suggests that progesterone should not be given indis-

criminate to all cases of threatened abortion. Only about 40% of cases show evidence of progesterone deficiency as determined by pregnanediol excretion tests, and the administration of progesterone to the others may encourage abortion. Therefore the overall results for any large series of cases are probably better if progesterone is not used at all.

(b) The most important part of treatment is complete rest in bed, and that for at least a further seven days after all bleeding has ceased. This may be supplemented, at any rate in the initial stages, with morphine or such sedatives as the bromides or phenobarbitone. If possible, arrangements should be made for a biological test for pregnancy and for a pregnanediol estimation to be carried out on a first morning specimen of urine, and progesterone therapy should be withheld until the result is available. Synthetic vitamin E, 30 mg. thrice daily, appears to help sometimes and can do no harm. After the symptoms have settled down the patient needs to live a restful life, avoiding coitus and travelling, and she may continue to take vitamin E.

Combined Pertussis Vaccine and Diphtheria Prophylactic

Q.—There seems to be some difference of opinion about the combined injection of pertussis vaccine and A.P.T. Is there any contraindication? The anti-pertussis vaccine is sometimes given at monthly and sometimes at weekly intervals. Which do you advise, and why?

A.—The main objection at present to the combination of a pertussis vaccine with diphtheria prophylactic is that we still cannot tell whether any particular pertussis vaccine will prove an effective immunizing agent or not. If, therefore, a poor pertussis antigen is combined with A.P.T. its failure to protect children against whooping-cough may adversely affect the attitude of parents to diphtheria immunization and they may decide that prophylactic injections in general are of little value. Another objection is that immunization against whooping-cough should be begun as early in life as possible, say at 3 months, since infections may occur early and are most severe in infancy. On the other hand, diphtheria prophylactic is more useful and probably more effective if given towards the end of the first year of life.

The optimum dosage or interval of injection with pertussis vaccines is still not known. There is some evidence that a better antibody response is obtained by injections at three- or four-week intervals than by weekly injections, and the present tendency is to give two or three injections of 10,000 million to 30,000 million organisms at monthly intervals. The combination of pertussis vaccine with diphtheria prophylactic has no inhibitory effect on the antibody response to either antigen; indeed, the antitoxin response to diphtheria prophylactic is usually enhanced when a combined antigen is used.

Intravenous Iron

Q.—What is the present opinion of parenteral iron preparations? What are the methods of use and dosage? I have a woman patient, aged 27, who has a severe iron deficiency anaemia which responds rapidly to iron therapy. Unfortunately, in spite of trial of every oral form of iron, she shows a marked intolerance to this treatment, which causes abdominal pain and diarrhoea whenever it is given. Her haemoglobin level is now about 50%.

A.—Intramuscular injections of iron are not widely used in Britain, as an adequate amount cannot be given without risk of toxic symptoms and the injections tend to be painful. Nissim (*Lancet*, 1947, 2, 49) reported the use of intravenous saccharated iron oxide. The commercial preparation "ferrivenin" is now available for the treatment of hypochromic anaemias which prove refractory to oral therapy. Each 5-ml. ampoule contains 100 mg. of elemental iron as an iron-sucrose preparation, and it is claimed that there is "100% utilization" of such iron as compared with about 14% for ferrous sulphate and 1.5-3.0% for ferri et ammon. cit. taken by mouth. A test dose of 1.5 ml. is injected intravenously on the first day, 3 ml. on the second, and subsequently 5 ml. or 10 ml. either daily or on alternate days until a "satisfactory response" is obtained. Intravenous injections should be carefully performed, and it is important to prevent any of the iron solution escaping into the tissues.

Reactions—for example, malaise, pain in the back, etc.—may occur, but are uncommon. When injections are given slowly (about 2 ml. a minute) venous thrombosis does not often take place and no "washing through" of the needle with glucose saline is necessary. As 25 mg. of iron are calculated to raise the haemoglobin 1% it is reckoned that each ampoule should increase the haemoglobin by about 4%. A large infusion of 5% glucose with 2% ferrivenin has been suggested in order to avoid repeated venopuncture. Further reports of the latter technique are awaited. In the case mentioned, intravenous iron would seem well worthy of trial. In every case of so-called refractory iron deficiency anaemia, however, it is all-important to make sure that the anaemia is not secondary to such conditions as reticulosis, neoplasm, or nephritis, and that there is no evidence of blood loss.

Fat Intolerance

Q.—A man of 56 is very intolerant of fat, and it is thought that recurrent infections may be due to too low a vitamin A intake. All the usual preparations of vitamin A cause digestive disturbances. Could carotene be given instead? Is it unwise, in general, to give vitamin D in concentrated form to elderly people?

A.—There is no evidence that recurrent infections in man are due to a low intake of vitamin A. If it is desired to give this patient supplements of vitamin A, liquid vitamin A conc., B.P., may be administered in daily doses of 1½ minims (0.09 ml.). This is suspended in oil, but surely so small an amount would be tolerated. In any case, it could be administered in food without the patient's knowledge. Carotene can be given instead, if necessary, in the form of tablets containing 4,500 units (daily requirement, 4,000 units). Actually carotene is equivalent to just over half its weight of vitamin A, so that the dose would be two tablets daily. Carotene is absorbed from the gut and converted into vitamin A in the body. There is no objection to old persons taking vitamin D concentrates, provided they do not take more than approximately 800 units daily. Why not give the patient a combined preparation of vitamins A and D? There are preparations available 1 minim (0.06 ml.) of which contains a day's requirements of vitamins A and D.

Ammoniacal Dermatitis in Infants

Q.—What causes ammoniacal urine and the associated dermatitis in babies, and what can be done to prevent it?

A.—There are two main theories about ammoniacal dermatitis in infants. The first is that a urea-splitting ferment in the napkins sets free ammonia. Hence the treatment is to kill the ferment by boiling the napkins after soaking them in perchloride of mercury solution overnight, and to apply soothing powders or calamine lotion to the inflamed skin. The other view is that ammonia is set free by the action of soda in the napkins upon combined ammonia salts in the urine. If excessive acid bodies are being passed as a result of fever or too much fat in the diet, then there is more combined ammonia in the urine as the outcome of a renal compensatory mechanism, with a greater chance of ammonia being liberated. Here it is important to reduce fat in the dietary, to give alkalis by mouth, such as citrate 5 to 10 gr. (0.32 to 0.65 g.) three times a day, and to use boric powder freely in the napkin area to mop up free ammonia. If the dermatitis in boy babies goes far enough to produce a meatal ulcer, then boric ointment should be applied. Either theory or both may be correct. Experience in welfare-centre work suggests that adoption of the second view gives better practical results as a working basis.

Insulin Sensitivity

Q.—A woman aged 75 suffers pain on injection of protamine zinc insulin, and subsequently reddened, indurated, tender swellings appear at the sites of injection. Bacterial contamination has been excluded. I am informed that all brands of insulin now come from a common "pool." If this is the case, is there any other form of insulin that can be tried?

A.—The varieties of insulin available differ to some extent, since the processes of extraction from the pancreas and methods of purification are not identical. As one brand of protamine zinc insulin is causing local reactions, the two others should be tried and the one which gives the least reaction persevered with.

The swellings will probably soon disappear, but if they do not the method of desensitization outlined in the answer to the question on sensitivity to insulin (*British Medical Journal* Sept. 20, 1947, p. 475) should be adopted.

Athlete's Foot

Q.—It has been reported to me that there was an increase of athlete's foot last summer and that the persons affected had attended the public swimming-baths. Now it is winter, what is the best way to disinfect the duck-boards, as they appear to be a possible source of infection? What would be the best way to disinfect them in the summer, apart from scrubbing them with soap and water daily?

A.—It is doubtful if duck-boards, etc., are a very serious source of infection, but in winter a thorough treatment with formalin would probably be wise, followed by scrubbing with soap and water. This measure could also be employed occasionally in the summer.

NOTES AND COMMENTS

Leukoplakia and Kraurosis Vulvae.—Mr. STANLEY WAY (Newcastle-upon-Tyne) writes: In "Any Questions?" (Dec. 4, 1948, p. 1005) your writer gave a brief and concise account of kraurosis and leukoplakia of the vulva, and, in giving the incidence of the association of carcinoma of the vulva with leukoplakia, quoted along with the figures of Bonney and Taussig my own findings as published in my recent Hunterian Lecture to the Royal College of Surgeons. In your issue of Jan. 1 (p. 42) Dr. Elizabeth Hunt states that when cancer occurs in association with leukoplakia it is found on the internal surface of the vulva only, and from this she concludes that excision of the vulval skin is not justified. This statement is completely erroneous. I cannot give the exact figures for my last 100 cases, but I can state with certainty that in the last 20 cases of cancer of the vulva which I have treated and in which leukoplakia existed the external surface of the vulva was affected by tumour in every one. In six both the external and internal surfaces were involved with tumour, and only in two was the tumour confined to the mucous surface, but this was extensively affected by leukoplakia. Is Dr. Hunt not aware that both the skin and the mucous surfaces can be affected by this disease? I think it is probable that some cases of leukoplakia of the vulva may never become malignant, but there is absolutely no means of telling which are which, and therefore I feel most strongly that immediate excision of the leukoplakic vulva is the right and proper treatment. Cancer of the vulva is one of the very few examples of malignant disease in which prophylactic treatment can be applied with a fair measure of success. It seems a pity then that your readers should have doubts about this put before them by such an authority as Dr. Hunt. Finally, whilst I would agree with Dr. Hunt that there are lesions of the vulva which are wrongly called leukoplakia, there are far more lesions which are given high-sounding names by dermatologists but which are in fact the disease which less ambitious gynaecologists are content to call leukoplakia.

Rh Factor and Pregnancy.—Dr. S. A. DOXIADIS (Sheffield) writes: In "Any Questions?" (Jan. 1, p. 42) it is stated that in the presence of Rh antibodies in the mother's blood the infant should be transfused "without delay if its cells are found to be sensitized to Coombs's test." May I suggest that unless the writer had in mind replacement transfusion his advice is contrary to the opinion of many experienced workers? To give an ordinary transfusion to an infant before it becomes anaemic is unjustified and potentially dangerous. It is further stated that "there is little or no danger to the first foetus from this cause (presumably haemolytic disease of the newborn) unless in twin pregnancy." As far as I am aware twins are not more likely to be affected by this disease than single foetuses either in the first or subsequent pregnancies. Should there be any evidence for such a likelihood a reference to it would be much appreciated.

Correction.—In the note in "Books Received" (Jan. 15, p. 104) on *Cardiology* by Dr. W. Evans, we should have stated that his book is intended for postgraduate students and medical practitioners as well as medical students.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JANUARY 22 1949

THE SECRETARY REPORTS

THE BETTERMENT FACTOR

185% FOR PROFESSIONS

The B.M.A. has recently taken the opinion of an expert economist on the change in the cost of living for professional families from mid-1939 to the end of 1948. The data available have enabled him to make the comparison between 1938 (average) and October, 1948, but he considers that the comparison holds true for the other dates because prices in the middle of 1939 were about 1% higher than in 1938, and a little higher at the end of 1948 than in October, 1948. The increase in the cost of living is the percentage increase in money income needed by a family—in this case an average professional family—to obtain the same satisfaction or to maintain the same standard of living as in a given base period (1939). A family is assumed to make all the substitutions (e.g., cheaper for dearer items) which it can make under the existing market conditions.

In practice a rather different index is obtained—namely, one showing the increasing cost of a fixed budget. The amounts actually bought in the base period are repriced at the ruling prices at a subsequent date, no substitutions are allowed and no account is taken of rationing, controls, and other limitations on consumer choice.

Incompleteness of evidence precludes a precise formulation of a cost-of-living index for other than working class families, the corresponding indexes for middle class families can be estimated only very roughly. An additional difficulty in inferring a middle-class index from a working-class index is that, even if the two types of family paid identical prices for every individual item, the fixed budget used in the comparison is different for the two classes. A reliable figure for the increase in cost for working-class families from 1938 to October, 1948, is 75%. In making the working-class figure applicable to the middle classes two modifications are required.

The index is based on eight groups of commodities budgeted for—food, rent and rates, clothing, fuel and light household durables, miscellaneous goods, services drink and tobacco. The first step is to raise the price changes in three groups for upper middle-class families—food, clothing, and miscellaneous goods—to allow for the fact that these families purchase "luxury" items in these groups and that the prices of luxuries have risen more than the average. The price increase from 1938 for household durable goods is probably higher for middle class families. But this is offset by the fact that middle-class families consume more spirits and less beer and more electricity and less gas than working-class families. The price increase is less for spirits than for beer, while the price of electricity is actually lower than in 1938. The distribution of expenditure on these eight groups is apportioned differently for working-class and middle-class families therefore the second step is to allow for this by "weighting". This makes a good deal of difference in the final index figure, since the weights—i.e., the

distribution of expenditure—are very different. In percentages, the costs of the pre-war budget at prices in June, 1947, are given in Table I.

Tables II and III illustrate the indexes of retail prices with those for 1938 (average) taken as 100.

TABLE II—Working class Families Index of Retail Prices

	Weights	Average 1938 = 100			
		Average 1946	Average 1947	June 1947	Oct., 1948
Food	348	129	137	138	148
Rent and rates	88	105	103	110	109
Clothing	97	171	175	175	200
Fuel and light	65	142	147	145	163
Household durables	71	205	219	215	234
Miscellaneous goods	35	140	145	145	158
Services	79	138	145	145	153
Drink and tobacco	217	241	274	285	316
All	1 000	150	160	161	175

TABLE III—Upper Middle class Families Estimated Index of Retail Prices

	Weights	Average 1938 = 100			
		Average 1946	Average 1947	June 1947	Oct., 1948
Food	122	190	213	215	232
Rent and rates	50	105	103	110	109
Clothing	172	204	210	210	240
Fuel and light	6	142	147	145	163
Household durables	67	205	219	215	234
Miscellaneous goods	140	175	185	185	202
Services	317	138	145	145	153
Drink and tobacco	126	241	274	285	316
All	1 000	167	178	179	194

In round figures the increase from 1938 in the cost of the pre-war budget of upper middle-class families was, in 1946, 67%, in 1947 78%, and in 1948 94%. Nevertheless, these figures do not represent the increased cost of living. If there were free choice of goods and services the figures would generally be biased upwards. But choice is limited at present in various ways (e.g., by rationing), though in a few cases it is still possible to substitute cheaper for dearer items—e.g., greater use of electricity, which is no dearer than in 1938, as compared with gas, which has risen considerably in price.

The index given assumes controlled rents and is appropriate only to families still renting houses at pre-war rentals. Families occupying houses bought before the war will have somewhat higher housing costs than pre-war because of an increased repair bill, for families who have rented or bought houses since the war the rental or housing cost can be considerably higher than before the war, but the effect would not be large on the over-all index.

The index is one of market prices—i.e., prices inclusive of indirect taxation and after allowing for subsidies. The economist considers that in relating prices to salaries it is better to use an index of factor prices (deducting indirect taxes and adding back the subsidies). No official index of factor prices is available and he has assumed that for upper middle-class families it may be 5-10 points lower than the index of market prices given here.

He concludes that a fairly conservative estimate for use in determining professional salaries would put the level of prices at the end of 1948 at about 185% of that at the end of 1939.

TABLE I

	Food	Rent and Rates	Clothing	Fuel and light	Household Durables	Misc. Goods	Services	Drink and Tobacco	All
Working-class families	34.8	8.8	9.7	6.5	7.1	3.5	7.0	21.7	100
Upper middle-class families	12.2	5.0	17.2	0.6	6.7	14.0	31.7	12.6	100

National Health Service

SPECIAL REPRESENTATIVE MEETING

A Special Representative Meeting will be held in March in accordance with a decision taken by the Council at its meeting on Jan. 12, a report of which appears on another page.

SPECIALISTS' REPRESENTATIVES

The following are the members of the Joint Committee of Consultants and Specialists, which represents these practitioners in discussions with the Government:

Chairman.—Sir Lionel Whitby.

Royal College of Physicians.—Lord Moran, Professor W. G. Barnard, Dr. H. E. A. Boldero.

Royal College of Surgeons.—Lord Webb-Johnson, Mr. E. F. Finch, Mr. R. McNeil Love.

Royal College of Obstetricians and Gynaecologists.—Sir William Gilliatt (deputy chairman), Mr. H. J. Malkin.

Royal College of Physicians of Edinburgh.—Dr. J. D. S. Cameron.

Royal College of Surgeons of Edinburgh.—Sir Henry Wade.

Royal Faculty of Physicians and Surgeons of Glasgow.—Dr. W. R. Snodgrass.

Consultants and Specialists Committee established by the British Medical Association.—Dr. T. Rowland Hill, Mr. C. E. Kindersley, Mr. W. S. Mack, Mr. A. M. A. Moore, Mr. R. L. Newell, Mr. T. Holmes Sellors.

N.H.I. FINAL SETTLEMENT

The Distribution Committee, on which the B.M.A. has representatives, will meet at the end of January to decide the final payments due under the N.H.I. scheme. The settlement will include those payments due for the first four days of July, 1948.

NATIONAL MORBIDITY INQUIRY

PROFESSIONAL SECRECY MAINTAINED

The Hospital In-patient Summary—a form used to provide information for the National Morbidity Inquiry—requires for its completion full details of the patient's clinical condition as well as of his identity (name and National Registration number). The completed form will pass through lay hands, and the profession has objected that confidential information obtained in the course of professional work will be disclosed. The Ministry of Health agrees that professional secrecy must be preserved, and, at the B.M.A.'s representation, has altered the instructions on filling in the form so that only the patient's initials and the numerical part of his National Registration number are required.

AREAS CLOSED BY M.P.C.

SECOND LIST

The Medical Practices Committee has decided that the number of doctors providing general medical services in the following places is adequate (for first list see *Supplement*, Dec. 11, 1948, p. 214):

Fairford district (Gloucester county and city).

Garston district (Hertfordshire).

Hastings

Helmsley district (North Riding of Yorkshire).

Irby, Heswell, Barnston, and Pensby (Cheshire).

Lustleigh, Bovey Tracey, and Moretonhampstead (Devon).

St. Helens and Sea View district (Isle of Wight).

Stanmore district (Middlesex).

Sussex West (districts in West Sussex adjacent to Hindhead, Grayshott, and Haslemere districts in Surrey).

Washington, Ashington, Dial Post, Sleepy Hollow, and Storrington (West Sussex).

HEARD AT HEADQUARTERS

Hospital Appeals

When Mr. Bevan announced that hospitals must no longer appeal for money by means of flag days, advertisements, and so on he emphasized "that boards or committees should not participate directly or indirectly in appeals or in collections for their hospitals." Mr. John Dodd, Honorary Secretary of the British Hospitals Contributory Schemes Association (1948), protests that this interdict must not apply to the members of these boards or committees taking part in the existing contributory schemes. There are 35 schemes providing benefits to their members and dependants supplementary to those obtained free under the National Health Service, and some in addition collect charitable contributions for medical research and medical charities. Government spokesmen have agreed that there is still an important place for such work. We can see no reason why members of hospital boards should not continue to devote some of their time to such an entirely worthy purpose as charity for the sick.

Display Cards

One of the difficulties that the Whitehall administrators have to face is that most men do not like being administered. Apparently many insured persons are failing to quote their National Insurance number when claiming National Insurance benefits. This causes delay in payment of the benefit and additional administrative work. The Ministry of National Insurance has therefore prepared a card for exhibition in suitable places reminding people to quote their number when claiming. The Ministry would like the card to be displayed in doctors' waiting-rooms, among other places, and they are sending them round to executive councils with the request that they should be distributed to doctors. On being consulted by the Ministry about this, the B.M.A. told them that doctors must decide individually whether they want to show the cards or not; the B.M.A. sees no objection to their doing so.

Sorry to Trouble You

A doctor sends us the following letter which he received from a patient:

Dear Dr. X.,

Many thanks for sending permit to buy vacuum flask. I should be grateful if you will kindly send me permits as below:

(1) Surgical shoes.

(2) Bi-focus glasses (my reading-glasses were stolen from Rest Room).

(3) Artificial teeth.

When not too busy, perhaps you would call in, if further explanation is necessary? So sorry to trouble you. With many thanks in anticipation,

Yours sincerely,

A. B. C.

P.S.—Since leaving off cow's milk, the indigestion is very much reduced. Nestle's condensed milk suits fine. But the allocation is insufficient. My grocer says, "Ask your Dr. for a permit, and the Food Office will supply."

I should like 6 tins per month. So please:

(4) Permit for Nestle's Cond. Milk.

Nutrition Survey

The documents considered and the reports prepared by the special B.M.A. committee on nutrition already make a considerable library. A subcommittee was set up to examine data on family consumption of food, but it felt that the word "family" was too restricted and therefore decided to investigate all the available information about food consumption during and since the war. Yet at the end of its heavy labours this small committee confesses its concern at the lack of recent data, and one of its recommendations will be that machinery should be provided for ascertaining at regular intervals the consumption of food by representative groups. The result of its investigation is very much what might have been concluded from individual experience—that the supply of calories has been maintained and of most nutrients increased, but there has been deterioration in variety and palatability. This is supported by a mass of authoritative information.

British Medical Association

PROCEEDINGS OF COUNCIL

Wednesday, Jan. 12, 1949

A meeting of the Council was held at B.M.A. House, London, on Jan. 12, with Dr. H. Guy Dain in the Chair.

The death was reported of Dr. Lewis Lilley, who was a member of Council for 12 years and for a much longer time a member of the Insurance Acts Committee. The Chairman, in a brief tribute, spoke of Dr. Lilley's quiet but effective service and his versatility. The members stood for a few moments in silence.

The Council congratulated the 25 members of the Association whose names were in the New Year Honours List.

It was agreed that the business proceedings of the Annual General Meeting at Harrogate should take place, following the Representatives' Dinner, on Monday evening, June 27, and that the Sections should start their work on the Tuesday morning, though the Annual Representative Meeting could continue on that morning if necessary.

It was intimated that Mr. Zachary Cope, having been appointed chairman of the Ministry of Health committee which is to make a full inquiry into the question of auxiliary medical services, had resigned the presidency of the Board of Registration. The Council nominated Mr. A. M. A. Moore, already a member of the Board, for the presidency, and Mr. N. Ross Smith to fill the vacancy in the membership.

Dr. James Fenton and Dr. J. A. Ireland were appointed by the Council to attend the congress of the Royal Sanitary Institute at Brighton in May, and Lord Horder was invited to represent the Association at a conference on cremation to be held at Hastings in June.

REMUNERATION IN THE NATIONAL HEALTH SERVICE

Demands for Special Representative Meeting

A number of resolutions from Divisions were before the Council concerning remuneration in the National Health Service. Eight of them called for a Special Representative Meeting.

The Secretary (Dr. Hill) made the announcement which appeared in last week's *Journal* that as from July 5, 1948, the Mileage Fund, which had stood at £1,300,000 a year, would be raised to £2,000,000 a year, an increase of more than 50%. Of the £700,000 increase £200,000 would come from the Special Inducements Fund, but half a million was new money. The enlarged fund would meet general mileage and mileage for rural practitioners under the maternity scheme. The General Medical Services Committee, jointly with the Joint Committee of Consultants, was proceeding immediately to deal with the betterment factor. The betterment factor could not await the Whitley Council arrangement, for until this factor was determined the remuneration of consultants and specialists could not be fixed.

Dr. H. H. D. Sutherland said that the announcement concerning mileage was satisfactory, but practitioners could not live on mileage grants alone. There was a great deal of discontent throughout the country, and he hoped that a Special Representative Meeting would be summoned. Dr. N. E. Waterfield said that the profession was entirely dissatisfied with the capitation fee, and a number of doctors were facing financial disaster because of its inadequacy and the decline of private practice. Dr. W. Jope said that the discontent arose over the matter of the betterment factor. Dr. S. F. L. Dahne said that there was immense dissatisfaction, and it was important for the Council to have a clear policy.

A resolution from the Harrogate Division urged that immediate steps be taken to ascertain the legal position, if necessary by a test case in court, with regard to the withholding of free drugs from private patients. It was stated to be the legal view that under the Act as it stood at present public prescriptions could be presented only for N.H.S. patients; the remedy was a clause in the Amending Bill. Dr. J. A. Gorsky said that the

legal opinion was based on Sect. 38 of the Act, which placed a duty on local executive councils to provide free medical services for all who had signed on doctors' lists, but Sect. 1 still remained, which declared that it was the duty of the Ministry to provide free medical services for all. In reply to Sir Ernest Graham-Little the Minister had said that he could not allow the provision of free medicines for private cases, because diagnosis, treatment, and provision of drugs must all be regarded as part of one process. That, of course, was an *ipse dixit* of the Minister—not a regulation. Later the Minister seemed to have changed his position, and in reply to Sir W. W. Wakefield he said that the reason he would not allow free medicines for private patients was because the doctor would have no responsibility for observing the general provisions governing prescribing at public expense. Again, in reply to Mr. Thorneycroft, the Minister agreed that a pregnant woman might engage a doctor privately and pay his fees for her confinement without losing the nursing and other benefits available under the N.H.S. If nursing and other benefits could be provided freely to private patients in maternity cases there was surely no justification for denying to private patients the right to free medicine under the Act.

Dr. J. A. Pridham raised the question of the Special Inducements Fund and the effect of its depletion in order to increase the mileage allowance. The Chairman said that the Ministry had stated that there had been very few applications for grants from the Special Inducements Fund. A request had been made to the Minister that the "lid" should be taken off that fund, which should be made available to practitioners to any extent necessary, but the answer was that practitioners were chary, apparently, of making applications.

On the general question of practitioners' incomes, the Secretary stated that even though the overall picture in Lancashire or anywhere else might prove to be mainly satisfactory, individual doctors, particularly in the higher-class or mixed suburban areas, had lost substantially in income. It seemed necessary to move away from the mathematical overall application of "Spens" and get closer to the actual position as it affected groups of practitioners, particularly those with lists of average size and less. The Chairman added that the "Spens" income was intended to be for a reasonable amount of work, but it was now discovered that the practitioner with a moderate list as well as the one with a large list was being overworked.

In reply to a question concerning payment calculations it was stated that certain payments had not yet been made, as, for example, for July 1 to 4—the final payments under National Health Insurance—and the temporary resident payments; these were some of the unknowns, but there were also certain "knowns," the 5% for contingency, and the amount retained in respect of the practitioner's contribution to super-annuation and the amount existing in respect of the Government's contribution. When this was taken into account it was conservatively estimated that the quarterly cheque, multiplied by four, with 20% added, represented the annual income. In the case of rural practitioners these figures required to be modified by the new mileage arrangement.

Special "Panel" Conference and Special Representative Meeting

Following this general discussion the Council agreed to suggest to the General Medical Services Committee that when it had completed its survey of the information available it should consider the desirability of calling before the end of February a Special Conference of Local Medical Committees to express the general practitioner view on remuneration. The Committee would consider this request at its meeting on Jan. 19. Dr. Gregg pointed out that it was necessary for the material for this Conference to be well considered; it must not be a flash in the

pan—a yell of protest with no weight or mass of evidence behind it. The Council also decided, following the expressions of opinion already made, to summon a Special Representative Meeting in March, before which the conclusions of the Special Conference would be placed.

Mr. Lawrence Abel mentioned the position of consultants, many of whom, he said, were suffering extreme degrees of hardship, having sustained not a 25 or 50% but in some cases a 90% diminution of income. The Chairman said that the Council very fully appreciated the hardships of consultants.

Lord Horder raised the question of the demise of the Negotiating Committee, and asked whether it was a case of homicide or *felo de se*. The Chairman said he had sent out a letter to the members of the Committee, and had had no suggestion from any member for its continuance. With the setting up of the General Medical Services Committee and the Joint Committee for Consultants and Specialists it seemed advisable now to revert to the ordinary machinery. Lord Horder said that he agreed, but it was a constitutional point, and the Council which had originally set up the Negotiating Committee and had invited other bodies to participate should be consulted on its dissolution. The Council formally approved the action taken by the Chairman in bringing the Negotiating Committee to an end.

The Council set up a committee to draw up a full list of amendments to the Act required by the profession in the light of experience. The subcommittee consisted of the Chairmen of Council, of the Representative Body, of the Conference of Local Medical Committees, of the General Medical Services Committee, and of the Consultants and Specialists Committee, with Mr. Lawrence Abel, Dr. Frank Gray, Dr. J. A. Gorsky, Dr. A. Staveley Gough, and Dr. N. E. Waterfield.

PROPOSED REORGANIZATION OF CENTRAL COUNCIL

Dr. J. A. Pridham, chairman of the Organization Committee, introduced certain proposals for the reform of the method of election to the Central Council of the Association. He said that it was a very difficult task to rearrange the method of election of an elected body. For a considerable time it had been evident to some of them that there was a weakness in the link between the Council and the periphery. The Winchester Division, which had taken an immense amount of trouble over this subject, had issued a memorandum which had gone out to the Divisions. The Organization Committee found itself in general agreement with the aims of that Division though it might differ on details. Resolutions had also been received on the subject from the North of England Branch. It was axiomatic that members of Council should be well known to the rank and file of the Association, and that the rank and file should have a good voice in choosing them. As matters stood, however, out of a possible Council membership of 66, only one-third were directly elected by members in the Divisions and Branches at home. The chief point in the Committee's proposals was that this number—22—should be increased to 42, but without any significant enlargement of the total membership. This would be effected chiefly by the elimination of certain of the *ex-officio* members, who now numbered 12, and by the abandonment of the method of electing twelve members of Council by grouped representatives at the Annual Representative Meeting. It was considered by the Committee that the eight members of Council elected by the Representative Body as a whole offered a sufficient opportunity for "elder statesmen" to have a place on the Council and also for those who had demonstrated their capacity at Representative Meetings to gain a place. But the election of twelve by grouped representatives had tended rather to become a means of temporary escape from disappearance from the Council on the part of those who had completed their six-year tenure of office as members directly elected by the Divisions and Branches.

The new Council, if the Committee's proposals were accepted, would consist of 8 *ex-officio* members, 42 directly elected by home Branches, 8 directly elected by the Representative Body as a whole, 3 Service members, 2 members representing the Public Health Service, 1 woman member, and up to 7 members from overseas. The distribution of seats of the 42 directly elected members would be 31 for England, 3 for Wales, 6 for Scotland, and 2 for Northern Ireland, which retained, but did not increase, the "weighting" in favour of the three latter

countries. Dr. Pridham concluded by saying that this would be a gesture to show that the Council was fully alive to its duties and responsibilities by making drastic and even self-sacrificing alterations in its constitution.

Dr. O. C. Carter considered that the Winchester memorandum was ill-informed when it stated that the Council was out of touch with the rank and file of the profession. Had it been so they would have heard of it, and they had not heard of it. The increased membership of the Association was not an argument for changing the method of election to the Council; it was not as if a new geographical area had been brought in. He thought that there were many arguments for retaining the election of twelve members, by grouped representatives.

Dr. Waterfield said that electoral areas were much too large, and if there were more directly elected members it would be possible to have smaller areas. He himself spoke as representative of the Southern and Surrey Branches, but it was rather a hardship to Hampshire that it should continue to be represented by a Surrey member.

Dr. Dahne and Mr. A. S. Gough supported the proposals, the latter saying that, while the election by grouped representatives had much to recommend it, the electors knowing their candidates, the disadvantage of losing this method would be offset by having smaller electoral areas in the country.

Dr. S. Wand considered that the Organizing Committee had failed to recognize that the geography of this country from the medical point of view had changed during the past year. It had become a country of regions, and whether for the purpose of elections those regions should be divided into two or three segments or whether two or three members should be elected by the region as a whole was one which the Committee should discuss. In the Association they would have to think in terms of regions rather than of Branches. He thought also that a Council of over 70 members was too large, that it was unnecessary to retain three Service members, and that power of co-option should be given. Dr. P. J. Gibbons also thought the reorganization should be regional, but Dr. J. G. Thwaites held that there was no valid reason why, because hospital organization was regional, the Association, which had completely different functions, should be organized on a regional basis. Dr. A. Beauchamp thought the Council should see the whole picture of the new constituencies before arriving at a decision.

Dr. F. Gray said that the advantage of election by grouped representatives was that people were elected who were personally known to those electing them; they were likely to be people attending frequently at Headquarters and whose work for the Association was known and appreciated. With the disappearance of that mode of election a valuable element would be removed from the Council. The weak link in the Association was not between the Council and the periphery but between the members of the local executive or those who came regularly to Association meetings on the one hand and the rest of the profession on the other, and that would not be strengthened by these proposals.

Dr. R. G. Gordon held that before these proposals were discussed in detail it should be considered whether a new distribution of Branches was desirable. As things stood, the cart was being put before the horse. Dr. J. C. Arthur considered that full information should be given about the distribution of electoral areas and the possibility of fitting Branches into hospital regions before reaching a decision.

The Chairman suggested that in view of the discussion the Organization Committee should give the Council an opportunity of seeing a map of the constituencies in their relation to regions.

Dr. Pridham said that the Committee had had a map before it and had some ideas on redistribution but had not wished at this stage to put them before the Council. He undertook to bring the matter forward again at a later meeting of Council with this additional information.

Public Health Salaries

On the recommendation of the Public Health Committee, presented by Dr. R. H. H. Jolly, the Council resolved to inform the Minister of the serious unrest and dissatisfaction among members of the public health service occasioned by the continued delay in opening negotiations on the new scales and

conditions of service, and, further, that if negotiations through approved Whitley machinery were not begun by the end of February advertisements from local authorities would not be accepted by the *British Medical Journal* unless the salaries offered were in conformity with the Association's own proposals for the new scales. The recommendation was passed by the Council unanimously. It was pointed out that the Association's proposals for the new scales and conditions were submitted to the Ministry as long ago as July, 1948, and in spite of repeated efforts it had not yet been possible to open negotiations.

General Medical Services Committee

Dr. Wand, presenting the report of the General Medical Services Committee, covered again some of the ground of the earlier discussion in the Council on remuneration. He said that the Committee was exploring all possible methods of improving the position of general practitioners who had suffered financial hardship as a result of the introduction of the National Health Service. It was collecting information from four county areas and two county boroughs which would enable it to form a reasonably reliable estimate of the extent to which the *Spens* recommendations were being implemented. A pilot inquiry was also being made into the extent to which the volume of work had increased since the introduction of the Service. One point which was being taken up with the Ministry was the question of the number of general practitioners in the Service in excess of 17,900, the figure on which the Central Practitioners Fund was based. The Ministry had been asked to agree the correct figure as soon as possible with a view to the increase of the fund by the appropriate proportion. He hoped it might be left to his committee to deal with this and other points as they arose.

Dr. G. MacFeat said that the Highland and Islands Committee and the Rural Practitioners Committee in Scotland had discovered that practitioners did not like to apply for Special Inducements Fund payments because they regarded it as the acceptance of charity. The practitioners concerned had been asked to state their working expenses and an endeavour was made to build up a case from these. Dr. J. A. Ireland said that one of the reasons why claims on the fund were not made was because practitioners were not yet in a position to know exactly how much they were down on their practices.

Consultants and Specialists

Mr. R. L. Newell presented the report of the Consultants and Specialists Committee. The terms of reference of the Committee had given rise to some doubts, and the Committee proposed and the Council agreed to amend them so that they would read that the Committee

"shall be an autonomous body with full powers to determine policy and action on consulting and specialist and hospital matters through the administrative machinery of the Association. The decisions of the Committee within that sphere shall not be subject to approval of the Council or the Representative Body."

Mr. Newell reported that after much discussion a joint committee had been formed with the Royal Colleges and Royal Scottish Corporations, thus providing an appropriate and effective machinery for presenting the views of consultants and specialists through one channel to the Ministry. Sir Lionel Whitby, President of the Association, had accepted the chairmanship of the joint committee.

Dr. Wand drew attention to the financial position of junior hospital staff. The method of appointment of new house-men at the moment was causing anxiety because men studying for a higher degree found that the jobs which would be suitable for them with that end in view had already been taken by men holding that degree, of whom there were at present a large number available. He hoped that a subcommittee would be set up to deal with this problem and would include young men who could give first-hand information. Mr. Newell said that his committee was aware of these facts and had drawn the attention of the Ministry to the financial position of these junior officers, many of whom were over 30, married, and with a family. The Committee was deeply concerned in all aspects of the problem.

Private Practice

Dr. Wand, on behalf of the chairman of the Committee, Dr. I. D. Grant, who is not a member of the Council, also presented the report of the Private Practice Committee. Some of the

subjects included in this report were recorded in the account of the Committee proceedings in the *Supplement* of Jan. 8 (p. 13).

Women Medical Officers in the Armed Forces

Sir Percy Tomlinson, chairman of the Armed Forces Committee, asked the Council to rescind a resolution which it passed in June, 1947, in support of the Medical Women's Federation in its representations to the Government on the employment of women doctors in the armed Forces. He recapitulated the points he had made at the previous meeting of the Council, to which a reply had now been made by the Executive Committee of the Federation. He considered that the equality for which women doctors asked was not really equality but privilege. Physically a woman could not perform a number of jobs which fell to a man in the Army; she could not be in the front line; as a doctor she was the equal of man, but on the military side she was not equal. The Council had passed its resolution in 1947 without being aware of what was to be said from the military point of view. In the Navy no women were sent to any fighting ship, and on inquiring into the position in the U.S. Army and Air Force he had been informed that the existing regulations made no provision for commissioning female physicians and surgeons into the medical corps.

Dr. Janet Aitken said that women doctors had never claimed that they should or could do in the armed Forces exactly the same things as men. All they had said was that if they were called up as doctors they should be called up in the military forces. They did not seek privilege; they sought only the same opportunity as men to do their duty to their country. It was said that because women doctors could not conveniently go into the front line they must not be commissioned in the R.A.M.C. This was to forget that large numbers of men doctors in the R.A.M.C., as in other branches of the Army, never went into the front line, nor even left this country, but no one thought of saying that they should not be in the R.A.M.C. During the war the Navy had women doctors in its service under exactly the same terms as men, and this was true of the American Army and Air Force, whatever might be the position in peacetime.

Surgeon Rear-Admiral W. H. Edgar, R.N., said that it seemed likely that in the near future women would be entered in a women's corps and seconded for service in the R.A.M.C. Air Commodore J. Kyle described the position in the R.A.F. Two points in the women's service in the R.A.F. differed from men's: the women were taken into the W.R.A.F., and so far as their terms of service were concerned a permanent commission with pension was not visualized. Dr. W. M. Knox pointed out that in modern warfare not more than 25% of the forces were ever in the front line, so that the main argument of the Armed Forces Committee did not seem to hold water. The Council would make a great mistake if it rescinded this resolution.

The Chairman said that the Government was at the moment considering the establishment of women's units. Should the Council go back on anything it had done in the past when it was likely to be confronted very soon with a new set of circumstances? It would be wise to wait until the nature of the new set-up was known. The Council would never give way on the question of the equality of medical women as such, but there were other problems which arose in connexion with the fighting Services.

It was agreed to pass to the next business, the Council's resolution of June, 1947, still standing.

Medical Ethics

It was agreed on the recommendation of the Central Ethical Committee that a further edition of the *Medical Practitioner's Handbook* should be prepared at an early date, as it seemed essential for the principles and details of medical ethics to be brought to the notice of all newly qualified members of the profession.

The Council also expressed the opinion that while the position in law might be that a practitioner suitably qualified might enter his name on two or more lists under the National Health Service, for example, as a general practitioner and an optician or a pharmacist or both.

"This possibility is deplored on the ground that it is beneath the dignity of the profession so to act and may promote unethical practices."

One member mentioned that a certain practitioner, in addition to being on the medical list and the ophthalmic list, was on the pharmacists' and the opticians' lists, though now on these latter lists the word "limited" was added to his name.

The Committee, in reply to a request, had also recorded its opinion that it was undesirable for an optician to use a doctor's surgery, as it might lead to unethical practices. A request had been received for a ruling on the association of doctors with central clinics established by dispensing opticians without the approval of local ophthalmic medical practitioners.

Finance and Journal

The Treasurer (Mr. A. M. A. Moore) reported that up to the previous day, Jan. 11, subscriptions had been received from a rather larger number than had paid during the first eleven days of 1948. There was no indication of any extensive change in the membership of the Association. The membership now topped 60,000. Regional offices had been established at Oxford, Cambridge, Leeds, Sheffield, and Liverpool, and shortly there would be a regional office in Manchester.

Dr. O. C. Carter, for the Journal Committee, explained certain difficulties in carrying out the suggestion that the *Supplement* should be stitched separately and inserted loosely in the middle of the *Journal* so that it could be taken out and filed. Other suggestions were being considered.

The Chairman congratulated the Journal Committee, the Editor, and the Secretary of the Association on the recent improvement in the appearance of the *Supplement* and in the informational value of its contents.

Dr. G. Ostlere was appointed on probation an assistant editor of the *Journal*.

Special Committees

Lord Horder presented an interim report on behalf of the Committee on Nutrition. He said that the work of the Committee had proved to be rather larger than was expected. Four subcommittees had been formed, and a great deal of information had been collected and authoritative opinions obtained. Four reports would be published, together with an introduction, and it would be for the Council to decide what should be done with the report, and whether some more popular presentation of the conclusions should be made. He said how highly the Committee appreciated the exceptional help given by its secretary, Dr. A. Macrae.

Dr. Mary Esslemont presented a report from the Committee on Nursing. It dealt with the proposals for nursing legislation which had been submitted confidentially by the Ministry of Health. The Committee had made certain observations on these proposals, and the Council agreed that further representations should be made to the Ministry in accordance with these observations, and that steps should be taken to secure appropriate amendments of the proposed Nursing Bill.

Dr. J. G. Thwaites introduced a further report of the Joint Committee (with the Magistrates' Association) on Psychiatry and the Law. The Committee has prepared a memorandum on criminal law and sexual offenders, and the Council agreed that this be approved, published in the *Journal*, and also circulated in appropriate quarters. Several members of Council spoke in praise of the document as containing most constructive and sensible suggestions.

Dr. R. P. Liston reported for the Film Committee. He said that the Committee was anxious to encourage the production of medical films, but it could not commit the Association financially for such a purpose. Certain reputable pharmaceutical houses, however, undertook the production of medical films, which had generally found favour with the profession and had been ethically acceptable, although, of course, the firm concerned obtained a certain advertising value. The Committee was anxious to sponsor the production of a film on the treatment of infections of the fingers and hands, and the opportunity had arisen for the production of such a film under auspices which would ensure that the work was of high standard and formed a valuable contribution to the subject.

The Council agreed to a recommendation that such a film be made.

Scottish and Welsh Committees

Dr. G. MacFeat brought forward a report for the Scottish Committee on Whitley Council machinery for those employed

in the National Health Service. The Committee, for reasons which were set out in the report, favoured the early institution of standing Whitley Council machinery' to deal with the terms and conditions both of doctors employed under the National Health Service Acts and those employed by local authorities. He brought forward a recommendation that it should be a condition of the Association's acceptance of such machinery that it covered all doctors in these categories, and that it should contain a provision for a standing Scottish Committee of the medical functional council to which should be referred matters needing special consideration in the light of Scottish experience. This recommendation was agreed to, and, on the Chairman's suggestion that Scotland should not proceed further until a Whitley Council was established for the whole country, Dr. MacFeat agreed to defer consideration of certain further detailed proposals.

A proposal for the appointment of an Assistant Scottish Secretary was referred to the Staffing Committee, the Secretary being asked to make a report to the Committee.

Dr. H. R. Frederick reported that the Welsh Committee was making continued efforts to secure increased representation of the medical profession on hospital management committees. The Committee was also reviewing its own constitution and functions.

Other Business

Dr. Dain reported for the Committee on the Constitutional Position of the Association, which had held two meetings. It was hoped to have a report available for a special meeting of the Council in February so as to enable the report of the Council to be submitted to a Special Representative Meeting in March. The Council favoured the proposal that the Special Representative Meeting should be called for two days, one day to be devoted, as already decided, to terms and conditions under the National Health Service, and the other to the constitutional problem.

The Coroners Acts Committee, following upon representations from the Consulting Pathologists Group Committee, brought forward certain amendments in detail of the recommendations concerning mortuary accommodation and pathological facilities which appeared in the last Annual Report of Council. The Committee and the Council agreed: (1) To amend Clause iv of the recommendation contained in paragraph 118 of the Annual Report of Council, 1947-8, and approved by the A.R.M., 1948, as follows:

(iv) That mortuaries be made available at central points in each coroner's jurisdiction, equipped with refrigeration and a separate viewing room for relatives, the post-mortem room being furnished with good lighting, heating, and an ample supply of running water, and with facilities for the collection of specimens for histological and toxicological examinations; that the assistance of trained mortuary attendants be made available; that adequate transport facilities for bringing cadavers to the central post-mortem establishment from outlying mortuaries be provided; and that exception be not taken to the use of the local hospital mortuaries for the conduct of necropsies provided the pathologist nominated by the coroner is given facilities to use these premises for the purpose.

(2) To substitute the following recommendation for that contained in paragraph 119 of the Annual Report of Council, 1947-8:

That as an interim measure urgent consideration be given to the adoption of practical steps for mobilizing pathologists and enabling them to travel to the various outlying mortuaries, but that whenever practicable the cadaver be brought to the pathologist for examination.

Dr. R. G. Gordon reported that the Committee on the Post-graduate Education of General Practitioners had been fortunate enough to secure the services of Sir Henry Cohen as its Chairman.

The Council resolved to appoint as its delegates to the British Commonwealth Medical Conference at Saskatoon from June 7 to 9 the President of the Association or, failing him, the Immediate Past-President, and the Chairman of Council or, failing him, the Chairman of the Representative Body.

It was agreed to appoint a part-time Public Relations Officer for Scotland.

Routine reports were presented on behalf of the Office, Building, Charities, and certain other committees.

Questions Answered

Superannuation and Pension

Q.—Is a G.P. entitled to superannuation as well as retirement pension at 65 years of age? My son is a full-time student (medical), and I do not see much point in paying for unemployment stamps for him (except for a hypothetical widow's benefit) if he is not so entitled.

A.—For entrants to the National Health Service after July 5, 1948 (as distinct from those who entered on July 5, 1948), the contributions and pensions payable under the Health Service Superannuation Regulations will be reduced to take into account the National Insurance retirement pension of 26s. a week. This is being done in all public service schemes. The reduction in the Health Service pension varies for different classes, but in general it will be in the neighbourhood of £1 14s. a year for each year of contributing service during which the reduced contributions have been paid.

Change of Job

Q.—I cannot afford to continue in practice here. Will you please say when and whether I can claim compensation and refund of superannuation contributions if (a) I enter another branch of medicine, (b) I enter some occupation outside medicine?

A.—Under Regulation 13 of the National Health Service (Medical Practices Compensation) Regulations, 1948, the compensation payable to a practitioner will be paid on his retirement from practice or death, whichever occurs first. For the purpose of this regulation retirement from practice means retirement from practice as a medical practitioner providing general medical services under Part IV of the Act or under Part IV of the National Health Service (Scotland) Act, 1947. A practitioner receiving compensation on retirement from practice in the Service does so without prejudice to his right to engage in other fields of medical work.

In regard to superannuation, a general practitioner's superannuation rights are preserved if he enters another branch of medicine within the National Health Service—for example, if he accepts a hospital appointment. If he leaves the Health Service without having become entitled to any of the benefits of the superannuation scheme his contributions will be refunded with 2½% compound interest.

Schoolboy from Overseas

Q.—I am resident and domiciled in Jersey. How does the N.H.S. affect my son, aged 8, who is at a preparatory school in the United Kingdom? He is on the school doctor's list, but how is the doctor paid? Jersey being outside the U.K., the N.H.S. does not apply, and we pay no contributions.

A.—The benefits of the National Health Service are not limited to those who are contributors under the National Insurance Scheme. Neither are they limited under the Act as it stands at present to the people of England and Wales. The Minister has announced that the facilities of the Service are available to visitors from overseas. Your son is therefore entitled to general-practitioner attendance under the Act, and if his name has been placed on the list of the school doctor that doctor will receive remuneration by way of the ordinary capitation fee.

Leave with Pay

Q.—I assume that the holders of resident B appointments in the N.H.S. are entitled to leave with pay. If a practitioner has a six-months contract, how much leave is he entitled to take, and can it be taken during the end of the six-months period or has he to wait until it is completed?

A.—Present position: Hospital residents are part of the "transferred" staff of hospitals during the interim period. Their terms and conditions of service have been unaltered, and consequently if there was any agreement with regard to holidays that arrangement would still stand. If no agreement exists it would be perfectly reasonable for a resident to ask for, and expect to receive, two weeks' leave in six months. This has

generally been the custom in connexion with resident appointments—e.g., in the old Middlesex County Hospitals residents were allowed to take two weeks at the end of their six-months appointment and often took their two weeks' pay for holiday following the termination of the appointment.

Provision will be made for the holiday leave of residents in future contracts.

Pensions and the Elderly

Q.—I was 68 when I entered the Service on July 5, 1948. Although it seems to say in the regulations that a doctor is entitled to a pension after 10 years' service, the Ministry has told me that, owing to my age, even though I do 10 years' good service, I shall not be entitled to a penny of pension. Why is this? Also, the Ministry of National Insurance has told me that, owing to age and having been a non-contributor before July 5, neither I nor my wife, who is 20 years younger than me, can stamp cards and get 26s. a week and 16s. respectively when I retire. Why is this?

A.—"Service," for the purpose of the regulations, means service after attaining 18 years of age and before attaining pensionable age. "Pensionable age" is the age at which contributions cease to be payable and service ceases to count. This is normally 65 years of age, but for practitioners on executive council lists it may be extended by the Minister up to but not beyond the age of 70. A practitioner who enters the Service after the age of 60, therefore, cannot qualify for a pension on retirement on age grounds, though he may qualify for an injury pension in the event of permanent incapacity through accident or injury arising from his duties (for which there is no qualifying period). If no benefits are payable under the scheme, the practitioner's contributions are refunded with 2½% compound interest.

On the second point the Ministry of National Insurance states:

"Your correspondent is not eligible to pay contributions under the main National Insurance scheme, and neither he nor his wife will therefore be able to qualify for its benefits.

"The position of elderly persons in relation to the National Insurance Act, 1946, received very careful consideration when the National Insurance Bill was being framed. It was decided, however, that it would not be possible to bring within the scope of contributory benefits persons who had already reached pensionable age (i.e., 65 for a man and 60 for a woman) and had no insurance qualifications at the start of the new scheme of National Insurance.

"The scheme is based on insurance principles and assumes that, in the normal way, benefits will be provided in return for contributions paid throughout working life until pensionable age is reached. In the case of a man this is a period of 49 years. Although considerable concessions have been made in the case of elderly persons who are liable to pay contributions up to the 65th birthday (60 for a woman) enabling them to qualify for a retirement pension after a minimum qualifying period of 10 years, it would not be possible to go further than this and extend the contributory benefits to persons who were over pensionable age at the start of the scheme."

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

SECRETARY TO LONDON MEDICAL COMMITTEE

At a recent meeting of the Executive Committee of the Wandsworth Division, Dr. Alexander proposed, and Dr. Walshe seconded, the following resolution: "That this meeting of the Executive Committee of the Wandsworth Division of the B.M.A. heartily congratulates Dr. Frank Gray on his appointment as Secretary to the Local Medical Committee for the County of London; expresses its grateful thanks to him for his invaluable services to the Division over a great number of years; and extends to him its sincerest good wishes for his health, happiness, and success in his new sphere of activity." The resolution was passed with acclamation.

Correspondence

Lack of Support for Negotiators

SIR,—A letter from Dr. G. M. Woddie (*Supplement*, Jan. 8, p. 16) has a sinister significance. He relates that the Nottingham Branch of the B.M.A., worried by the plight of rural practitioners, called a meeting on a Saturday afternoon to discuss what measures could be taken to correct it. Invitations were therefore sent to 120 members of the Branch, giving the purpose of the meeting, and only 15 attended, of whom seven were members of the executive.

One hears similar stories of sparsely attended Divisional meetings throughout the country. There are several explanations. Doctors are grievously overworked, dispirited, suspicious of their leaders, and generally apathetic and indeed despairing. I want to point out what I think may be a very serious outcome of this absenteeism from meetings. A large part of the administration of the general practitioner service will be in the hands of local executive councils and local medical services committees. Both of these bodies have a delicately balanced composition. On both committees half the members are lay and half professional, with a lay chairman. If the professional members are slack in their attendance the lay members certainly will not fail to take advantage of the position, and a situation may come about in which the profession will be largely governed by local authorities, a fate which was feared and which was stoutly resisted at successive meetings of the Representative Body, whose opposition finally defeated the earlier proposals offered by the Coalition Government, which would have placed the local authorities in control of the profession. *Verb. sap.*

The framers of the N.H.S. Act, 1946, consistently sought to diminish the share allotted to the profession in the administration of the Health Services. A recent incident illustrates this tendency. At a meeting of the board of governors of a great London teaching hospital one of the newly added lay (Socialist) members broke into the discussion with the truculent observation, "It is time the medical staff realized that not they, but we, the lay members, are running this hospital now." The senior physician to the hospital, a member of the board, from whom I had this story, blandly countered with, "Perhaps you would prefer to run the hospital without the medical staff."—I am, etc.,

House of Commons

E. GRAHAM-LITTLE.

SIR,—The Honorary Secretary of the Nottingham Branch of the B.M.A. writes a complaint (*Supplement*, Jan. 8, p. 16) about the non-attendance of rural practitioners at a special meeting held in Nottingham on a Saturday afternoon. He appears to require a little instruction on the "facts of life" as they affect the rural practitioner (and others) at present. The simple truth is that the average G.P. has no time to attend meetings on Saturday or any other afternoon. Two long "surgeries" and visits sandwiched between give little time for travelling to Nottingham at this time of the year. I can assure him that most of us would consider attendance at such meetings a luxury or relaxation.

He also says that "to safeguard our interests we must act in an organized fashion." Now where have we heard that one before?—I am, etc.,

ewark, Notts.

J. J. KENNEDY.

Payment per Item of Service

SIR,—It is to be hoped that the survey of sample practices being investigated will yield some information on the question of average payment per item of service under N.H.S., a point I have never yet seen mentioned. I believe that under N.H.I. the figure was about 1s. 6d. when the capitation fee was 9s. 6d. At present N.H.S. rates it is therefore unlikely to be more than 2s. 3d., and probably much less, since more women, elderly patients, and children are now at risk.

When one considers that 10s. 6d. is considered a fair fee for an antenatal examination carried out at the surgery, the average payment for other services is economically ridiculous, and on this basis the capitation fee should be at least trebled. If we cannot obtain payment on an item-of-service basis, like

our dental or New Zealand colleagues, then we should at least receive a capitation fee that gives us a fair average payment.

Another point which must be borne in mind in considering sample practices is the amount of private practice remaining in them. Any loss of income shown by them is likely to increase as time goes on and private practice contracts still further, so that in addition to actual loss shown at present some estimate should be made for increasing loss.

If it is found that the average payment per item of service under N.H.S. is, say, 2s. 3d., then we are $x-2s. 3d.$ worse off each time we see one of our erstwhile private patients, where x = the fee previously paid. In effect, it may be argued that we are subsidizing our old private patients so that they may maintain their standards of living. This was well exemplified by a remark made to a colleague by a patient: "I am afraid I shall have to join the Health Service after all. I have had so many expenses lately. I have just had to buy a new fur coat."

In spite of what I have just written about capitation fees I still consider that the New Zealand system is fairest and would be most acceptable to doctor and patient alike. The latter is relieved of financial worry, the former is paid on a basis of actual work done, and by raising his fees in certain instances above the Government level he can receive extra payment for special attention and services, or use that means as a deterrent to the over-demanding patient. It is, moreover, a means of raising standards to those of the best private practice instead of lowering them to the worst panel standards, as is bound to happen under the present system, which will also lead to a lowering of quality in future entrants to general practice. What inducements now exist to the prospective entrant to take higher degrees or do a series of postgraduate appointments when he is ranked by the Minister on the same level (16s. a head) with a man with minimum diplomas and no special experience?—I am, etc.,

Malvern, Worcs.

G. JAMIESON MEIKLE.

Some Fundamentals

SIR,—In the smother of words poured out before and since July 5 we are inclined to forget the fundamentals for which we should assiduously campaign:

- (a) A bigger capitation fee.
- (b) A country doctor with 2,500 on his list to have income parity with a city doctor with 4,000.
- (c) That compensation be related to a special cost-of-living index based on, say, the price of a car and several articles of clothing and food. (What will the position of the £1 be in 30 years when some are claiming their compensation?)
- (d) Paid locums for illness and holidays.

And the better to implement these, our Association should go ahead without delay and become a firmly knit trade union.—I am, etc.,

Dungannon, Co. Tyrone.

C. MCCLUSKEY.

A Quarter's Pay

SIR,—I have kept a careful record of the daily number of visits and consultations during the last quarter, and I find that the cheque (gross, before the deduction of superannuation) recompenses me by the amount of 3s. 7d. per visit or consultation, leaving nothing for telephone consultations, letters, certificates unaccompanied by visit or consultation, telephone charges for calls incurred on behalf of patients, or postage ditto. This 3s. 7d. rate is applicable also to minor operations performed in my consulting-room and to sewing up heads after accidents. I am interested to find that I have visited more patients than I have seen at my house.—I am, etc.,

Bristol.

H. K. V. SOLTAU.

Contact Between Hospital Bodies

SIR,—Sir Frederick Menzies calls attention (*Supplement*, Dec. 11, 1948, p. 220) to the "staggering" increases in hospital costs since 1939; he estimates the current annual cost of the available 582,000 beds at not less than £200 million, and suggests a survey to secure reductions without which "the enormous cost may have serious repercussions on the medical services other than hospital work." It may be questionable whether a survey would serve the purpose for the following reasons. Up to July 5 last the position, as may be seen from the *Hospitals*

Year Book, was due to the progressive upward trend of all commodity prices and wages. These are not amenable to reduction by a survey confined to hospitals. From July 5 last onwards the State Service has introduced new elements, but it is not yet possible to assess the cost of reshaping the management, administration, supply, and staffing of the hospitals under the new conditions. It is, however, safe to prophesy that the costs for 1948-9 will be well above the highest yet recorded.

The situation is undoubtedly serious and demands that any practicable step to examine all its implications should be taken without delay. Might not one such step be to secure a closer association between those responsible for policy (the Departments of Health) and those responsible for carrying it out (the regional hospital boards, boards of governors, and hospital management committees)? There has been plenty of communication, devolution, and directive downwards. Ought there not to be an adequate corresponding channel upwards through which the various statutory hospital bodies, and others directly connected with hospital affairs, could discuss their problems and submit considered views based on their day-to-day experience? Two-way contact of this kind, particularly if established in the early and formative stage, would enable the many problems (including costs and such economies as could safely be introduced without detriment to the Service) to be brought under continuous review and could not but be beneficial to the development of the Service in every way.—I am, etc.,

J. P. WETENHALL,

Editor of the *Hospitals Year Book*.

London, W.1.

Father Christmas

SIR.—I received the enclosed letter to-day from a patient who has recently come on to my N.H.S. list. He has never consulted me professionally. It is such a beautiful example of the new status of the G.P. in his patient's eyes that I feel its publication might cause some rueful amusement.

"Will you please let me have a note for the chemist to obtain the following:

2 bottles Compound Syrup of Cocillana—for my cold.
75 'Benerva' vitamin B 3 mg (Roche product) for lumbago.
100 'Veganin'.
100 'Aspirin'. } for Mrs. A. and emergency.
100 'Anodin'. }

I enclose stamped addressed envelope Thank you."

—I am, etc.,

Seaview, I.O.W.

PAUL C. CONRAN.

* See also "Heard at Headquarters."—ED., *B.M.J.*

Unnecessary Night Calls

SIR.—It must, I am sure, be the lot of most doctors that they are from time to time called out at night-time absolutely unnecessarily. I was called out of bed at 12.30 a.m. not long ago by a woman's husband, who stated that his wife was "in agony with her throat." I hurried round prepared for an emergency, only to find the woman sitting up in bed and actually smiling. There were no abnormal physical signs whatever, and I did not mince words about this triviality for which they had had the effrontery to bring me round, and for their utter thoughtlessness.

I find that people on the whole are, if anything, ultra-considerate in their anxiety not to disturb a doctor at night. For the recalcitrant few who behave as the people I have described above I consider that there should be some redress for the doctor besides his prerogative in removing them from his list. I suggest that the doctor be paid a special fee by the local executive council, recoverable by them from the patients concerned. In this way these abuses would be considerably reduced, if not entirely eliminated.—I am, etc.,

B. SWEETMAN.

London, S.W.10.

Directives

SIR.—You have appended a footnote to my letter on directives (*Supplement*, Jan. 1, p. 7). I wish to let you see the directive as sent out on Dec. 10. It reads:

"I am requested by Mr. J. P. Mallett, the secretary of the Local Hospital Management Committee, to draw your attention to the fact that patients requiring medical and surgical appliances through the hospital services should be referred with a letter to the consultant

surgeon of the week at the Royal Salop Infirmary, Shrewsbury, and should attend on Wednesdays.

"It has been the practice of some practitioners to issue E.C.10's to patients requiring medical and surgical appliances which are supplied through the hospital service, and I shall be pleased if you will refrain from using these forms in future."

Now, I think you will agree that the last paragraph in particular does not make it clear that articles such as those mentioned in your note can be ordered on E.C.10. In fact, I have received word privately from the Clerk to the Salop Executive Council and from the Senior Administrative Medical Officer, Midland Region, admitting that such things as trusses can be so ordered. The point is, no amending directive has to date been issued although I have asked that this might be done.

We are all paying through the nose for this so-called Health Service. The administrative side of it is clearly costing so much that last week it was rumoured in the Press that in reply to a request from the M.P.U. the Minister replied that he had no more money to increase the capitation fee. We have the right to expect an efficient administrative branch at the price, and members of it making blunders such as this directive and refusing, it seems, to admit their mistake by issuing an amending directive should in my opinion be replaced by a more intelligent bureaucrat.—I am, etc.,

Ludlow, Salop.

VICTOR N. FENTON.

Basic Salary Warning

SIR.—I think a warning should be given to our colleagues who contemplate resigning from the State medical scheme not to do so until their claim for basic salary has been disposed of. The Clerk of the London Executive Council informed me to-day that the fixed annual payment of £300 is not granted to those practitioners who resign. I have therefore worked the scheme for six months under an illusion and at a financial loss.—I am, etc.,

London, S.W.6.

N. J. CALDWELL.

Promising to Resign

SIR.—I am in entire agreement with Dr. R. C. McIntosh (*Supplement*, Jan. 1, p. 8). The doctor has doubtless calculated that in advising the profession to resign there are some who approve the terms of service, some who do not disapprove, and many others who, though disliking them, are not prepared to take definite action. To render his proposal effective it will be necessary that he should appoint an accredited secretary (and why not himself?) to whom all who think as he does should write in the following terms: "I, X.Y.Z., hereby promise to resign from the N.H.S. on July 5, 1949, provided that 8,000 general practitioners do likewise. I enclose cheque for £100." 8,000 resignations is the smallest number which can be counted upon to be effective. The £100 is returnable after July 5, but would be retained for medical charity in any event of "ratting."

I only regret I cannot be one of the 8,000, since, fearing this very state of affairs, I refused to join the Service.—I am, etc.,

Braintree, Essex.

A. M. ROBERTS

Dentists' High Expenses

SIR.—The difference in gross income allowed to medical and dental practitioners appears less "farcical" than Dr. Gibson suggests when it is recalled that the Spens Committee found average dental expenses to be 52%, while in the higher income groups overhead expenses are often between 65% and 75% of gross receipts. There is also enormous initial and substantial recurring capital outlay, upon which a dentist is entitled to expect financial return.

All will agree that doctors carry far greater responsibility and have longer hours of duty (not work), but fewer perhaps appreciate the intense nervous strain involved in carrying out, often under water and by indirect vision in a very limited field upon a highly sensitive part of the body, operations which would entail great concentration even if carried out "on the bench." The intensity of this strain is revealed in the high incidence of nervous breakdowns, duodenal ulcers, etc., and by the very high death rate among dentists between the ages of 40 and 50.—I am, etc.,

Bognor Regis.

GORDON JEFFERY.

Prescribing in Rural Practice

SIR.—Under the N.H.S. the provision of medicines for patients living in country districts follows closely the arrangements made thirty years ago under the N.H.I., and little account seems to have been taken of the fact that transport in the country is now very much easier for the patient than it was in those days. To-day if my patient lives more than two miles from a chemist he has to come to my surgery to obtain his medicine. This may entail a journey for him of five miles or more. I would suggest that it be left to the discretion of the rural practitioner to decide in individual cases as to whether it is easier for the patient to obtain the medicines from the chemist than from the doctor. Such an arrangement would have other advantages too. A dispensing doctor can hardly be expected to provide a pharmaceutical service of the same range that a chemist provides. He may wish his patient to have some little-used drug which he himself has not stocked. A tedious delay is involved in the doctor's ordering it from a chemist and the patient's then obtaining it from his doctor. I suggest it could easily be made possible for such delay and inconvenience to be obviated altogether.

I would suggest that dispensing doctors be provided with prescription forms differing in some distinct manner from the present E.C.10. A different colour would be an obvious solution. The dispensing doctor would then, when conditions call for it, prescribe for his patient on this form, and the pricing bureau would know at once that it was issued from a dispensing doctor, and the doctor would be surcharged at the end of the quarter with all the prescriptions he had issued. As things stand at the moment there is a strong temptation for the dispensing doctor to avoid supplying any medicines to his patients that involve the tedious method at present required. No doubt this would involve an increase in administrative work, but surely the Minister would not shirk this. He would undoubtedly wish that, if the Service can be improved by harder work on the part of the doctors, then the doctors should work harder. The same surely should apply to the administrative side.—I am, etc.,

Wolston, Warwickshire

G. CAMPBELL.

Elderly G.P.s

SIR.—May I draw your attention to a manifold injustice which the older general practitioners are to suffer under the new Health Act? Those who were over 55 on July 5, 1948, do not qualify for pension until they have done ten years' service under the new Act, no matter how many years they may have put in in the underpaid service of the N.H.I. In the case of a doctor aged 61 before the new Act, who has completed twenty-nine years' service under the N.H.I. (apart from war service), there is no pension. If allowed to remain in the N.H.S. after the age of 65, he would have to be over 71 before completing ten years' service.

Surely, if the Minister is sincere in wishing all doctors to serve under his scheme, he should take practical steps to ensure the future of those now elderly practitioners who have given the greater part of their lives to the National Service in one form or another? With private practice largely destroyed, incomes reduced, living expenses increasing, what likelihood is there of saving enough to support old age?—I am, etc.,

Brighton

F. E. GORDON WATSON.

Supplementary Ophthalmic Service

SIR.—Your note in the *Supplement* of Jan. 8 (p. 13), entitled "Supplementary Ophthalmic Service," is a bit watered down from the circular letter to ophthalmic surgeons dated December, 1948. The latter with its veiled threats was a very unwise document, and I will not repeat the terms in which I described it in writing to our local representative on the Ophthalmic Committee. If a few men are sending in claims for large daily lists, it should have been a simple matter to warn them, or to place a ceiling on the number of cases to be paid for daily or monthly to any one individual. The rush of eye patients is phenomenal and they must be dealt with by somebody, and it is common knowledge that there are large waiting-lists in every centre. This is not the fault of the eye specialists, and our representative should keep on pointing out to Mr. Bevan that he has made a bad miscalculation instead of letting the idea

get abroad that the wicked eye specialists are making far more money than they are entitled to. What the country needs is more eye specialists, and any move now to lower fees will be a fatal blow at the recruiting.

All this talk about spending an average of half an hour with each patient is only eyewash. It isn't the minutes that will cure the patients if the skill isn't there or the examiner conscientious. I can quite understand an ophthalmic optician taking at least half an hour to do his examination, as he has never had enough training or knowledge to recognize an abnormality quickly, but it is just nonsense to say that every eye specialist must spend at least half an hour with every patient, especially when he can have all the actual clerical work done by somebody else.

Would he be subject to rebuke if he spent an hour making sure of an incipient glaucoma and then only quarter of an hour on each of two middle-aged presbyopes? All over the provinces there are responsible ophthalmic surgeons with busy hospital appointments who are trying to work off large waiting-lists of refraction cases in supplementary eye centres, and if they do see 20 to 25 cases in the days they can allot to this kind of work it is only done by the sweat of their brows and at the expense of what remains of their private practices. Moreover, I very much doubt if they gain much increase on their gross takings. If, as I fear, there is a scheme to lower the fees they would be justified in saying, "Not good enough," as they had to do in the bad old days of the N.O.T.B.; then the waiting-lists would be so lengthy that most of the sensible patients will save up enough for a prompt private consultation and the careless remainder will entrust themselves to opticians.

If this occurs Mr. Bevan's scheme will have failed irretrievably, and recruiting of enough young eye specialists will never materialize.

My advice to every ophthalmic surgeon is to write without delay to his regional representative and say that he will never agree to a reduction of the present fees, not alone because of his own circumstances but equally because of his hopes for the future.—I am, etc.,

Galton, Devon.

CECIL B. F. TRY.

Payment by Patients

SIR.—After six months' experience of the new Health Service we must agree that the major cause of dissent by both patient and doctor is finance. To the layman free treatment is off-hand treatment. I suggest a patient pays a nominal fee, say 1s., to consult his doctor and to prove his *bona fides*.

The trade unionist with his large stipend would be little affected, and there should be little repercussion on the mob vote. Our proctor's seat remains safe. The "vermin" need not approach us with diffidence, as is their present tendency, as pauper patients with no means of showing gratitude. It will deter the "something-for-nothing" brigade, and the doctor feels that his work is rewarded.—I am, etc.,

High Wycombe, Bucks.

G. E. CHURCH.

Basic Salary

SIR.—I would like to endorse the views of Dr. John A. Fraser (*Supplement*, Dec. 18, 1948, p. 232), who doubts the wisdom of the Negotiating Committee in opposing Mr. Bevan's proposal of basic salary for all practitioners joining the Service, which was amended later by him to basic salary for all practitioners who want it.

When the profession was asked to vote for or against basic salary the majority may have voted against basic salary because this question was at that time tied up with another more vital question regarding the ownership of goodwill. But when it became obvious that the B.M.A. could not persuade the Minister to allow practitioners to retain the ownership of their practices the majority of the practitioners must have felt that they had to assume the status of branch managers in a State-owned multiple store, and therefore it no longer mattered whether the remuneration was by salary or by capitation or both so long as it was adequate. This is obvious, without going to a third plebiscite, by the number of practitioners who voted against salary and have since applied for it and actually feel disconcerted owing to the refusal of their executive councils to make the award.

Moreover, for many practitioners who in the past have relied for most of their income on private practice built up after many years of service of a quality seldom to be found in any panel or State practice, and who now face great hardship, the basic salary was the only bright spot in the whole of the N.H.S. scheme. It is a great pity that the B.M.A. went to such lengths with the Minister to blot it out. It makes one wonder if it would not be better for the practitioners if the B.M.A. confined its activities to social and scientific proceedings, and left the representation of their financial interests in the hands of some other body better fitted for the task.—I am, etc.,

Nottingham.

G. CHAND.

POINTS FROM LETTERS

Cut in Dentists' Earnings

Dr. F. W. CHEESE (Stourbridge, Worcs) writes: . . . Mr. Bevan should have known the following facts, and if he did know them he should not have ignored them. Here are the facts: (1) A shortage of dentists has been known for many years. (2) That many dentists were called up for duty with the Services, resulting in the civilian population being left with a very depleted staff of dentists. (3) Most doctors have advised many of their patients to seek dental treatment and in many cases this advice was not acted on because of the expense. (4) For over five years the public have been promised free dental treatment when the new Health Act came into force. (5) Now the accumulated arrears of dental defects have come to harvest. Had the dentists been allowed to carry on without this threat to their earnings the vast arrears of work would very probably have been cleared off within two or three years. The rush of work would be over and dentists' work and incomes decline.

Act Now

Dr. J. McL. LEES (Walsall, Staffs) writes: Why are we bound to "Spend"? Let us demand a capitation fee (with only super-annuation deducted) which we consider adequate. If not granted, let us get out, and stay out, of the Health Service until our demands are met. . . . Professional ethics and our duty to patients have little if anything to do with our dealings with this Minister of Health. Let us give "Strike" Bevan the only argument he understands. Let us do it quickly. Enough of this awaiting reports—the *Journal* correspondence speaks for itself. Let us act now; it may soon be too late.

Employment of Assistants

Dr. W. B. HOWELL (Brenchley, Kent) writes: In his second letter (*Supplement*, Jan. 1, p. 8) Mr. Donald M. O'Connor suggests that I should read his first letter (*Supplement*, Nov. 13, 1948, p. 177) with more attention. I can still find little else in his letter but that he was disgruntled when he discovered that he could not carry an assistant employed by him on July 4 forward into the new Service and charge the expenses up to the Training of Assistants Scheme. If this was not the real point he wished to make in his original letter why introduce his first quarter's figures, as these were only relevant in so far that they indicated that he had been badly hit as the result of his being misled by paragraph 6 of the circular "Remuneration of General Practitioners"? The last sentence of this paragraph, that is, "Further details will be announced later," surely suggests that at the time of publication of the circular—April, 1948—the final details of the Training of Assistants Scheme had still to be decided upon, and that with so many more urgent problems awaiting negotiation these details would not have been settled in time to allow Mr. O'Connor to continue to employ his previous assistant on July 5 at public expense. . . .

* This correspondence is now closed.—ED., *B.M.J.*

The Ministry of Health states that the number of hospital nurses and midwives working full time in England and Wales rose by nearly 3,000 between June and September, 1948. In June, 1947, there were 115,500; in June, 1948, 118,000; and in September, 1948, 121,000. This total includes those trained and in training. Part-time nursing and midwifery staffs in hospitals show a rise of 2,000 between June and September, 1948, and of 9,000 over the 15 months from June, 1947. Comparative figures are: June, 1947: 10,700; June, 1948: 17,400; September, 1948: 19,500. There has also been an increase on the domestic side as follows. *Full-time domestic staff*: June, 1947: 99,400; June, 1948: 99,700; September, 1948: 99,700. *Part-time domestic staff*: June, 1947: 18,100; June, 1948: 21,600; September, 1948: 23,100. This general increase in hospital staffing has made it possible to institute a 96-hour fortnight in more hospitals, as well as to reopen beds closed through lack of staff. The point has now been reached when every addition to hospital nursing and midwifery staff means the opening of more beds or the improvement of working hours and conditions—sometimes both.

H.M. Forces Appointments

REGULAR ARMY: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Substantive Major W. H. R. Lumsden has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel.

War Substantive Captain W. Fabisch has relinquished his commission and has been granted the honorary rank of Major. (Substituted for the notification in a *Supplement to the London Gazette* dated July 6, 1948.)

Captains G. Grant and P. Venables have relinquished their commissions and have been granted the honorary rank of Captain.

Captain R. M. Ingliis has relinquished his commission on account of disability and has been granted the honorary rank of Captain.

War Substantive Captain J. D. McGregor has relinquished his commission on account of disability and has been granted the honorary rank of Major.

War Substantive Captains F. L. Potter, M.B.E., A. Gild, C. E. Hunter, S. Chatterjee, J. Sharkey, and W. C. D. Lovett have relinquished their commissions and have been granted the honorary rank of Major.

War Substantive Captain J. R. McGregor has relinquished his commission and has been granted the honorary rank of Major. (Substituted for the notification in a *Supplement to the London Gazette* dated Aug. 27, 1946.)

War Substantive Captains C. I. Humbert, B. G. Paul, D. Ungar, J. R. Harries, A. F. Crick, and P. Hogg have relinquished their commissions and have been granted the honorary rank of Captain.

Short Service Commission, Specialist.—Captain A. L. Wingfield has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel.

Lieutenants J. K. Baird, H. Baker, E. Barnett, F. A. Beale, T. L. Begg, J. Black, P. S. Brown, G. O. Clark, B. O. Clements, D. C. Cockburn, J. T. Crean, R. R. De-Mowbray, J. H. Fox, E. J. Gow, P. Hampson, D. G. Hardy, G. Hird, J. B. Howard, D. A. Jack, E. Jones, S. Kalinsky, J. B. Lawson, B. H. Lees, C. Levin, J. M. Loughran, G. I. Lumsden, C. D. R. Pengelly, R. L. Richards, J. B. Ritchie, M. J. Roper-Hall, B. Reubner, I. W. Sinclair, C. R. B. Stewart, R. G. Stewart, T. Symington, B. Towers, J. K. B. Waddington, R. J. S. Weir, P. M. C. Maik, A. D. Bangham, J. R. G. Bastable, K. R. Brookes, K. B. Chambers, J. I. Cohen, D. J. Crockett, P. J. Dwyer, J. B. Eades, D. J. Gardner, J. P. Graham, K. C. R. Halliday, R. H. Hansell, R. E. A. Hansen, J. M. Holmes, D. A. L. Jones, D. W. W. Jones, O. G. Jones, H. Keidan, I. A. Kellock, R. J. Klingglass, A. H. Levy, F. D. Lumb, H. Mackenzie, A. MacLennan, J. G. Maurice, K. R. Ogilvie, H. Rezler, A. R. Somner, W. A. L. Thompson, J. C. Whitlam, R. Wolfson, D. L. Woolf, and H. M. White to be Captains.

Lieutenant (War Substantive Captain) J. B. Stafford, from I.M.S., to be Lieutenant.

To be Lieutenants: A. C. Anderson, K. W. Blaikie, W. S. Bowman, W. W. Bryett, D. Cooper, D. McL. Cunningham, R. C. Davison, J. R. C. Fleit, B. Goodman, R. Hodgkinson, C. W. Hollingsworth, M. Hyman, W. Lees, R. Marshall, J. A. McCusker, B. V. McEvedy, J. E. Middleton, D. H. Miller, P. S. Moore, R. J. A. Nicol, D. J. Oakland, B. G. Pickles, P. Pratt, D. R. K. Reid, A. J. Russell, G. C. Ryan, J. D. Scott, P. W. Sergeant, B. A. Sheldermine, G. R. Tudhope, K. D. J. Vowles, N. MacG. D. Blyth, D. M. Cameron, J. A. L. Clark, P. J. Croxford, J. G. Dickson, D. E. P. Forbes, R. Gillott, R. I. MacP. Hepworth, J. A. G. Holt, H. A. Jones, K. M. Leighton, J. S. M. Low, C. C. Lutton, G. C. Manning, A. G. Milne, J. Newall, A. G. B. Poole, G. L. Ritchie, J. Savy, E. P. H. Short, D. W. C. Smith, B. J. Sproule, W. B. D. Storie, D. T. Sutherland, P. J. Walker, K. C. Watson, G. F. Watt, and E. W. Wright, T. Barker, A. J. Beale, J. D. Brackenridge, A. Bryce, E. J. Clegg, A. L. Cowan, J. M. A. Critchley, A. G. Davidson, W. W. Douglas, H. A. F. Dudley, E. J. Fairlie, J. Z. Garson, J. A. Gawthorpe, J. Gloster, E. W. Green, A. E. W. Gregson, R. D. Haigh, T. B. Hogarth, A. Hunter, A. H. Kitchin, A. G. McCallum, A. D. Macdonald, D. C. Morley, J. I. Murray Lawson, T. G. Osmond, F. J. Powell, R. H. B. Protheroe, D. M. Serr, J. R. Spears, S. Sternberg, W. M. Sutcliffe, I. W. Stoddart, K. H. Sykes, G. C. Turner, J. S. Washington, A. O. Wilson, B. Winocour, E. Hirsch, R. I. K. Blyth, N. L. Buckley, T. C. Dow, R. W. Doy, D. H. Forsdick, T. W. H. Forster, J. D. Fuller, J. D. Heighway, F. H. W. Johnson, D. E. Oakley, I. C. L. Patch, F. I. Powell, D. W. Purser, M. E. Y. York-Moore.

The notification regarding Lieutenant J. J. A. Reid in a *Supplement to the London Gazette* dated Oct. 8 has been cancelled.

The surname of Lieutenant A. Cledwyn-Davies is as now described and not as notified in a *Supplement to the London Gazette* dated Aug. 20.

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

Captain A. G. Harrison has relinquished her commission and has been granted the honorary rank of Major.

Captains A. Faulkner and M. H. Swift have relinquished their commissions and have been granted the honorary rank of Captain. Hilary E. C. Miller to be Lieutenant.

Association Notices

AREAS OF ST. HELENS AND WARRINGTON DIVISIONS

Notice is hereby given by the Council to all concerned that the urban district of Newton-le-Willows has been transferred from the St. Helens Division to the Warrington Division.

CHARLES HILL,
Secretary.

Diary of Central Meetings

JANUARY

25 Tues. Organization Committee, 2 p.m.

27 Thurs. Colonies and Dependencies Committee, 2 p.m.

Branch and Division Meetings to be Held

ALDERSHOT AND BASINGSTOKE DIVISION.—At Rotherwick Village Hall, Sunday, Jan. 23, 3 p.m. Subject: "Remuneration under the N.H.S."

BATH, BRISTOL, AND SOMERSET BRANCH.—At Musgrove Park Hospital, Taunton, Saturday, Jan. 29, 8.30 p.m. Address by Mr. John Barron: "Plastic Surgery."

EAST SUFFOLK DIVISION.—At Physiotherapy Department (old Nurses Lecture Room), East Suffolk and Ipswich Hospital, Friday, Jan. 28, 8 p.m. Lecture-demonstration by Mr. Ronald Raven on "Cancer," illustrated by clinical cases and epidiascope.

HENDON DIVISION.—At Hendon Hall Hotel, Wednesday, Jan. 26, 8.30 p.m. Dr. E. F. Rabey: "Some Practical Suggestions on the Diagnosis and Treatment of Backache."

HERTFORDSHIRE BRANCH.—At Methodist Hall, Marlborough Road, St. Albans, Friday, Jan. 28, 2.30 p.m. Address by Dr. Charles Hill: "Current Problems."

MARYLEBONE DIVISION.—At Manson House, 26, Portland Place, London, W., Friday, Jan. 28, 8.15 p.m. Discussion: "Present Situation in the Medical Profession."

METROPOLITAN COUNTIES BRANCH.—In the Great Hall, B.M.A. House, Tavistock Square, London, W.C., Thursday, Jan. 27, 8 p.m. Address by Dr. Charles Hill: "Terms of Service."

NORTH NORTHUMBERLAND DIVISION.—At Blue Bell Hotel, Belford, Thursday, Jan. 27, 7.30 for 8 p.m. Annual dinner.

SOUTH-WEST ESSEX DIVISION.—At Clinic Hall, Thorpe Coombe Maternity Hospital, Wednesday, Jan. 26, 8.30 p.m. Mr. Charles Donald: "Swellings and Sinuses in Childhood." To be illustrated by lantern slides.

WANDSWORTH DIVISION.—At South London Hospital for Women and Children, South Side, Clapham Common, S.W., Sunday, Jan. 23, 10.30 a.m. Clinical meeting.

WESTMINSTER AND HOLBORN DIVISION.—Joint meeting with Chelsea and Fulham and Kensington and Hammersmith Divisions at Post-graduate Medical School of the Royal Cancer Hospital, 24, Onslow Gardens, Fulham, S.W., Wednesday, Jan. 26, 8.30 p.m. Dr. P. E. Thompson Hancock and Mr. R. C. B. Ledlie: "Cancer of the Stomach." Open to all medical practitioners in the area of the Divisions.

Meetings of Branches and Divisions.

CAERNARVONSHIRE AND ANGLESEY DIVISION

The Annual Meeting was held on Dec. 19, 1948, at Bangor. The following officers were elected for 1949: Chairman, Dr. G. Idwa Griffiths. Vice-chairman, Dr. E. H. Morris. Secretary, Dr. R. Rees Prytherch. To be members of Branch Council: Dr. J. H. Hughes, Dr. Maddock Jones, Dr. D. Glanville Evans, Dr. G. Mansell Williams. To be members of executive council of Division: Dr. J. H. Hughes, Dr. A. Maddock Jones, Dr. D. Glanville Evans, Dr. G. Mansell Williams, Dr. Leslie W. Jones. To be members of Local Medical War Committee: Dr. I. Mostyn Williams, Dr. D. Glanville Evans, Dr. G. Idwa Griffiths; together with present members: Dr. A. Maddock Jones, Dr. W. Hilton Parry, Dr. C. A. A. Lever, Dr. D. Page Thomas, Dr. W. Charles Evans, Dr. D. E. Parry Pritchard, Dr. I. Mostyn Williams was elected representative on the Welsh Committee and Dr. G. P. Williams representative on the Representative Body.

The following resolution was passed unanimously: "That the meeting expresses extreme disapproval of the present position of the general practitioner under the National Health Service, and urges that there should be an immediate increase in the capitation fee to 30s (minimum), and that the mileage grant should be made adequate; that payment should be made monthly to doctors; that telephone, postage, and other overhead expenses of running a practice should be taken over and paid for by the Government." That there should be a Welsh secretary resident in Wales was proposed and carried. The reconstitution of the Welsh Committee was agreed to. Memoranda from Winchester, West Sussex, Brighton, and Birkenhead and Wirral Divisions were all supported wholeheartedly. A proposal that there should be £150 basic car allowance in addition to present mileage was carried.

THE USE OF SEX HORMONES IN THERAPEUTICS*

BY

P. M. F. BISHOP, D.M.

Endocrinologist to Guy's Hospital, Chelsea Hospital for Women, and the Department of Obstetrics and Gynaecology, British Postgraduate Medical School

Modern sex-hormone therapy is no more than fifteen years old, and, considering that progress was seriously retarded during the war, the rapidity with which this branch of therapeutics has expanded is remarkable. Few could have imagined that it would spread beyond the narrow confines of gynaecological endocrinology, and yet to-day sex hormones are beginning to play a prominent part in cancer treatment, general medicine, and such of its specialties as dermatology. It has therefore become the duty of every doctor to learn how to administer these substances

to lack of appreciation of its potency and the consequent tendency to use it in excessive doses.

Substitution Therapy in Gonadal Deficiency

The most logical use of sex hormones is to compensate for deficient gonadal secretion. To obtain the best results, however, it is well to distinguish between *congenital* and *acquired gonadal deficiency*. Ovarian agenesis and the failure of the testicles to develop or descend give rise to *objective signs*, such as infantile genitalia and scanty body-hair growth in both sexes, with amenorrhoea and lack of breast development in the female, and eunuchoidal lengthening of arms and legs and absence of beard and adolescent voice changes in the male. Embarrassment and introversion are understandable accompaniments of these serious physical defects in both sexes, but there is in addition a characteristic timidity which is especially noticeable in the eunuchoid youth and which, with androgen therapy, gives place to a more self-reliant, forceful, and aggressive personality. The aggressive properties of male hormone have been demonstrated in a fascinating study of the "peck order" in hens. Twelve hens from different broods when put together will quickly arrange themselves in a peck order, No. 1 hen pecking the rest and No. 12 being pecked by all. Administration of androgen to this last hen will, however, soon send her to the top of the peck order. Treatment of these mainly objective signs consists in intensive administration of sex hormones, preferably by pellet implantation. Breasts and the natural female curves may develop in the woman; beard and body-hair growth. Deepening of the voice, erections, and emissions may appear in the man, in addition to the awakening of male aggressiveness.

Acquired gonadal deficiency, on the other hand, leads to characteristic *subjective symptoms*, such as hot flushes, headaches, giddiness, lack of concentration, irritability, emotional instability, and easily induced fatigue, but to few or no objective signs. The severity of these symptoms varies from case to case. In most men and many women the climacteric is symptomless. At the worst the natural climacteric is a self-limiting condition readily controlled by judicious administration of the appropriate sex hormone. At the menopause the smallest daily dose of oestrogen which will appreciably diminish but not necessarily abolish the number and severity of the hot flushes should be determined by careful trial, and the aim should be to wean the patient as soon as possible from this dose. Overdosage leads, apart from the probability of annoying if not alarming uterine bleeding, to such symptoms as abdominal distension and headaches and not infrequently to return of the hot flushes.

Technique of Sex-hormone Administration

The sex-hormone compounds at present employed in this country, together with their routes of administration and dosage, are set out in the accompanying Table. The

Hormone	Route of Administration	Dosage		
		Low	Moderate	High
Estrogens:				
Natural:				
Oestrone	Oral	3,000-10,000 i.u.	—	—
Oestradiol benzoate	Injection	—	10,000-50,000 i.u.	—
"Oestrone sulphate"	Oral	0.625 mg.	1.25-5 mg.	—
Synthetic:				
Stilboestrol	Oral	0.1-0.5 mg.	1-3 mg.	5-15 mg.
Dienestrol	"	0.3-3 mg.	3-10 mg.	15-50 mg.
Hexoestrol	"	3-5 mg.	—	—
Ethinyl oestradiol	"	0.025-0.05 mg.	0.05-0.15 mg.	0.25 mg.
Progestogens:				
Progesterone	Injection	—	5-20 mg.	—
Ethisterone	Oral	—	20-50 mg.	—
Androgens:				
Testosterone propionate	Injection	—	10-25 mg.	50-100 mg.
Methyl testosterone	Oral	5-15 mg.	30-60 mg.	—

dose ranges are based not upon any universally agreed scale, for no such scale exists, but upon personal experience and opinion, except in the case of ethinyl oestradiol, which has only just been launched upon the British market and the figures for which are therefore taken from the American literature. Other routes of administration than by mouth and by injection are employed, but these will be specifically mentioned in discussing the conditions for which they are to be preferred. Nausea and other side-effects may accompany the use of any of the synthetic compounds, but fortunately the "toxicity" range usually lies well above the "low" and "moderate" therapeutic ranges, except perhaps in the case of stilboestrol, though even with this compound the high incidence of side-effects so often experienced is due

*A postgraduate lecture delivered at the Society of Apothecaries on Nov. 2, 1948.

Sudden deprivation of actively secreting gonads by castration in the adult of either sex, or by destruction of ovarian function with radium or deep x-ray therapy, at whatever age it is performed, may lead to a stormy climacteric, difficult to control and certain to be prolonged. In the male this may be characterized by frequent drenching hot flushes and physical weakness which may seriously interfere with work. Implants of four 100-mg. pellets of testosterone repeated every six months will fortunately control nearly every case. In women, however, the results of treatment of the artificial menopause are often less satisfactory, and the dose of oestrogen may need to be increased until there is likelihood of troublesome uterine haemorrhage unless the uterus has been extirpated with the ovaries. Not only do hot flushes occur, but severe headaches and intense depressions are in some cases such prominent and distressing features that every gynaecologist should be reluctant to deprive his patient completely, by whatever means, of functionally active ovarian tissue whatever her age may be.

Certain post-climacteric conditions seem, from their specific response to gonadal hormones, to be manifestations of sex-hormone deficiency. In women the troublesome itching of kraurosis vulvae and senile vaginitis will be promptly relieved by a short course of moderate doses of oestrogen. A somewhat rare condition of hyperkeratosis of the palms of the hands and soles of the feet (keratoderma of Haxthausen), with sore and bleeding fissures, is seen in the post-climacteric period and responds well to similar treatment. In elderly men the skin tends to become thin and atrophic, and this is sometimes associated with intense irritation, which may be relieved by androgen therapy.

Sex Hormones in Gynaecology

The female sex hormones control the events of the endometrial cycle which culminate in "menstruation," or uterine bleeding resulting from complete shedding within a period of three to five days of the superficial layers of an endometrium stimulated first to grow under the influence of oestrogen and subsequently to secrete under the influence of progesterone. Uterine bleeding may occur, however, in association with a variety of endometrial patterns, and is not so much a reflection of endometrial histology as of the changes in calibre of the endometrial vessels. These changes may be induced by a number of factors, and bleeding may be produced by non-specific drugs such as "prostigmin" (neostigmine). Oestrogens and progesterone, however, exercise a specific influence on uterine haemorrhage. Two oestrogenic patterns may be identified — the scanty and always painless bleeding which results from oestrogen withdrawal, and the prolonged, irregular, and usually excessive bleeding from a "metropathic" endometrium which occurs when oestrogen secretion or administration is long-continued and unopposed. Not only is oestrogen capable of inducing bleeding either by

withdrawal or by continued administration or secretion, but it may also arrest it or prevent it from occurring when the oestrogen level is raised or kept high. These somewhat paradoxical effects may be explained by Fig. 1. Progesterone on the other hand, can produce bleeding only from an endometrium which has previously been stimulated to grow or proliferate by oestrogen. Progesterone bleeding is characteristic of normal menstruation, and consists of complete shedding of the endometrium, or, as Fuller Albright describes it, a "medical curettage."

Probably the most dramatic result of the use of the sex hormones in gynaecology is the *haemostatic* effect produced by oestrogen in cases in which the bleeding has been prolonged and is alarmingly heavy. High doses given every four hours will arrest the haemorrhage in 24 to 36 hours. This treatment renders obsolete the scramble of a hurried curettage in an exsanguinated patient or the tragedy of a hysterectomy in a child with uncontrollable puberty bleeding. Eventual arrest of haemorrhage can also be achieved by opposing the action of oestrogen, and so lowering the bleeding level, by progesterone or androgen. Neither can be relied upon to stop the bleeding, however, in under four to five days, and they cannot be regarded, therefore, as effective emergency measures. Furthermore progesterone in the process of performing a medical curettage will make the bleeding even heavier before it stops.

In a case of *metropathia* in which ovulation fails to take place the constant and unopposed oestrogen influence slowly builds up the typical hyperplastic, vascular, polypoid endometrium from which the flooding eventually takes place. The characteristic picture, therefore, is one of amenorrhoeic phases, variable in duration but seldom lasting less than five or six weeks, alternating with bouts of haemorrhage, which at times is heavy and may be prolonged. These metropathic floodings may be anticipated and prevented by giving progesterone to induce a medical curettage two to three weeks after cessation of the last bleeding episode and therefore before the haemorrhagic bout is due

FIG. 2.—Prevention of metropathic flooding by rhythmical induction of medical curettage by progesterone.

to begin. Subsequent progesterone-withdrawal bleeding may be induced at any convenient regular interval, such as every 28 days (Fig. 2).

Two other types of abnormal bleeding are commonly found—*intermenstrual bleeding* often associated with short cycles, and a "*menorrhagia*," or excessive and sometimes prolonged bleeding occurring cyclically. Both are probably due to defective progesterone activity. Normally the appearance of progesterone in the second half of the cycle inactivates oestrogen, and the subsequent "menstrual" bleeding conforms to the characteristic progesterone pattern. Defective secretion of progesterone would therefore have two effects: (1) to fail to ensure the complete shedding which limits menstrual bleeding to four to five days, and (2) to permit active oestrogen to exert its characteristic influence on the bleeding pattern, leading to intermittent bleeding or heavy and relatively prolonged haemorrhage. One might therefore expect progesterone given in the premenstrual phase to prevent these types of functional bleeding from taking place. In practice, however, this is seldom the case, though the condition is often satisfactorily controlled by androgen given continuously in low doses for about two months. The intermenstrual bleeding may be treated by giving rather high doses of oestrogen daily

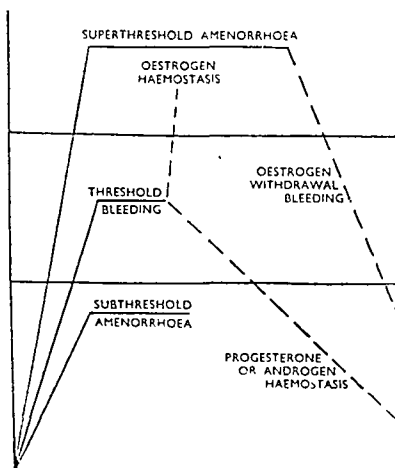

FIG. 1.—Oestrogen bleeding levels.

to the immediate premenstrual phase, though this often tends to produce a heavier "period."

"*Premenstrual tension*" is a syndrome of nervous tension, irritability, and depression, accompanied by a bloated feeling of abdominal distension and sometimes severe headaches and mastalgia. It is probably also due to defective progesterone production with incomplete inactivation of oestrogen. The symptoms are sometimes relieved by administration of ethisterone or low doses of androgens in the second half of the cycle.

Amenorrhoea usually results from ovarian deficiency, whether primary or secondary to failure of pituitary gonadotrophin secretion, and leads to sub-threshold oestrogen levels or to endometrial resistance or atrophy. Oestrogens are unlikely to restore normal ovarian activity or to overcome endometrial resistance. If given in fortnightly courses they may produce withdrawal bleedings which will raise false hopes in the patient. If given continuously they may, by inhibiting the pituitary control of ovarian activity, render the chances of spontaneous recovery less likely. *Amenorrhoea* is almost always compatible with blooming health, though it is frequently, but not always, associated with non-ovulation and consequent infertility. Treatment should therefore be confined to attempts to induce ovulation in those women who are anxious to become pregnant immediately; or to cases in which the *amenorrhoea* is accompanied by distressing minimal symptoms or is secondary to other causes, such as malnutrition, obesity, or chronic disease, in which case it is the other causes rather than the *amenorrhoea* which should be treated.

As for the treatment of *non-ovular infertility*, it is claimed that oestrogen followed by oestrogen and progesterone may stimulate the pituitary to release its gonadotrophins in the correct proportions to induce ovulation. Three or four courses of low to moderate doses of oestrogen given daily for three weeks, and ethisterone in addition during the third week, with a week's interval between each course, may occasionally be followed by one or two ovular cycles during which it might be possible for conception to take place.

Dysmenorrhoea is a condition of multiple aetiology, but one of the causes of spasmodic dysmenorrhoea may be powerful uterine contractions leading to ischaemia of the muscle. These contractions may be due to progesterone, and it has been asserted that spasmodic dysmenorrhoea occurs only in ovular cycles. Certainly it seems to be true that administration of progesterone increases the severity of the pain. In a condition in which results are notoriously difficult to assess it is not surprising that claims have been made for relief in a fair proportion of cases no matter which sex hormone or gonadotrophin is given. Androgens in high doses might be expected to suppress ovulation by pituitary inhibition and so render the subsequent bleeding painless, but it has been reported that equally successful results have been obtained with almost homoeopathic doses. Moderate doses of oestrogen will also suppress ovulation and result in a scanty withdrawal bleeding which is always painless. It would seem, therefore, that the best hope of relieving dysmenorrhoea by endocrine therapy is to suppress ovulation or produce an oestrogen-withdrawal bleeding, and there is no reason to believe that such treatment will have any effect on cycles subsequent to the ones in which it is given.

Sex Hormones in Pregnancy

Progesterone

Progesterone obviously plays an important part in the maintenance of pregnancy, especially in its early stages. Immediately embedding of the fertilized ovum begins.

chorionic gonadotrophin is secreted to prolong the life of the corpus luteum. Towards the end of the second month of pregnancy a "peak" excretion of very high concentrations of chorionic gonadotrophin can be observed—presumably ensuring the continued secretion of progesterone before the placenta itself takes over its elaboration. There has been some confusion concerning the functions of progesterone in pregnancy. Some years ago it was believed that it exerted a "sedative" effect on the uterine muscle and was essential, therefore, for the prevention of abortion, especially in the first third of pregnancy before the embryo was firmly embedded and the placenta fully formed. It is now known that progesterone induces contractions, at any rate in the non-pregnant uterus, which are forceful and of high amplitude, and it has for this reason been suggested that it should never be administered either prophylactically in cases of habitual abortion or therapeutically in threatened abortion. It would be understandable that, at a time when abortion is actually threatened, administration of a hormone which induces forceful uterine contractions, if indeed it does so in pregnancy, might be harmful.

The most important role of progesterone in pregnancy, however, is undoubtedly in relation to the development of the decidua and the formation of the placenta. Therefore a deficiency of the hormone, especially in early pregnancy, might lead to resorption of an embryo not yet securely embedded or adequately nourished. In such cases there would seem to be ample justification for progesterone therapy as early in pregnancy as possible, or indeed even before pregnancy is known to have taken place. Administration of ethisterone in the second half of each menstrual cycle, once pregnancy has been planned, with an immediate implantation of progesterone pellets once a period has been missed, should ensure the early prophylaxis which is required. Tendency to abortion, however, may be due to many and various factors, and this empirical use of progesterone without selecting the cases in which there is a progesterone deficiency will clearly result in many failures. Unfortunately, present methods of estimating pregnanediol do not always help in demonstrating such progesterone deficiency so early in pregnancy.

Oestrogens

It is the oestrogens rather than progesterone which are intimately concerned with the state of the uterine muscle. In the non-pregnant uterus they increase muscular tone and induce frequent contractions of low amplitude. In pregnancy they sensitize the muscle to the oxytocic effects of posterior pituitary extract. Since the concentration of oestrogens rises throughout pregnancy to a peak just before parturition one might well marvel that any pregnancy should reach term if the uterine muscle were to become increasingly sensitive to oxytocin. The fact is, however, that oestrogens are excreted in two forms, as "combined" or "conjugated" oestrogens (chiefly in the form of oestriol glucuronide), and as "free" or "unconjugated" oestrogens. Combined oestrogens have no effect on uterine muscle, whereas free oestrogens sensitize it to oxytocin. It is only immediately before parturition that free oestrogens appear in significant concentration. The conjugation of oestrogens is a characteristic step in their metabolism during pregnancy, and would apply equally to extraneously administered oestrogens as it does to the endogenous hormones.

In the light of these observations it becomes easier to rationalize some of the phenomena of oestrogen therapy in pregnancy. Oestrogens will be effective only when parturition has begun or the foetus is dead. They are therefore useless in the induction of premature labour, but may be helpful in the treatment of uterine inertia and in the evacuation of the uterus in missed abortion.

Sex Hormones and the Breasts

The very considerable species variation in hormonal control of the mammary glands makes it difficult to analyse the role of individual hormones in this complex mechanism. In some animals, such as cows and goats, oestrogens alone are capable of stimulating the various stages of breast development up to and including normal lactation, so that it may be possible with a stilboestrol implant to obtain copious quantities of milk from a virgin heifer or barren cow. In other species oestrogens are required for duct development, progesterone for subsequent acinar development, prolactin for lactation, and posterior pituitary hormone for expression of previously secreted milk.

In the human species breast development may be abnormally induced in the male (gynaecomastia) either by oestrogens or simply by testicular deficiency. Oestrogens may induce satisfactory mammary development in women with congenital gonadal deficiency, though attempts to increase the size of the breasts in women with normally developed but nevertheless small breasts usually lead to disappointing results. Furthermore, prolonged application of oestrogens to the breasts, conveniently given by inunction, in such cases may increase the tendency to develop generalized nodularity or fibro-adenosis ("chronic mastitis"). Whatever part the oestrogens may play in the aetiology of this condition, the symptoms of pain and tenderness experienced, particularly in the premenstrual week, are usually considerably relieved by small doses of androgen.

Though it is generally agreed that oestrogens exert a direct effect on breast development both in the non-pregnant and in the pregnant woman, it is also clear that through their action on the pituitary they may lead to inhibition of mammary function. Thus in the goat or in the cow it is possible for a relatively moderate dose of oestrogen to stimulate and initiate lactation, while a larger dose will inhibit the pituitary and suppress lactation. This pituitary inhibition is utilized in the case of the parturient woman who for one reason or another is not going to feed her baby. Relatively large doses given for about ten days, and started if possible before lactation has actually begun, will suppress the formation of milk and the painful engorgement of the breasts which accompanies it in the non-nursing mother.

Sex Hormones and Cancer

Evidence continues to accumulate concerning the intimate relationship between the sex hormones and tumours of the breast and uterus and of the prostate. In mice, mammary cancer can be induced by oestrogen administration in the males of a strain in which the females are cancer-susceptible. Women with carcinoma of the breast are five times more likely to have had a delayed menopause than women without breast cancer. If a woman with carcinoma of the breast becomes pregnant the tumour may grow at an alarming rate. Fibromyomas of the uterus and other structures have been produced in guinea-pigs, but not in other species, by administration of oestrogen. Carcinoma of the cervix has been produced in mice by giving oestrogens, and it has been suggested that the relatively high incidence of cervical cancer in multiparae is due to the fact that they have been submitted to the prolonged effect of their own oestrogens during pregnancy. Carcinoma of the prostate never occurs in eunuchs or eunuchoids: acid phosphatase appears in prostatic tissue only after puberty, but can be made to appear before this age by androgen administration. In patients with prostatic cancer and bone metastases it may be present in high concentration.

Nevertheless, despite these and many other suggestive observations, it is quite remarkable how few reports have

appeared of cancer of these organs following administration of the ipse-sexual sex hormone in human patients, and it would seem to be true of the human species that, though the influence of endogenous sex hormones may be an important factor in the development of certain neoplasms administration of the ipse-sexual sex hormones does not lead to the development of such neoplasms.

On the other hand, administration of the contrasexual hormones may have profound effects on the progress of certain neoplasms, and in particular carcinoma of the prostate and breast. Oestrogens were first employed for this purpose in the treatment of carcinoma of the prostate. It had been observed that orchidectomy arrested the progress of the condition, and it was hoped that oestrogens might produce a "medical castration" by inhibiting the secretion of pituitary gonadotrophins, thereby leading to testicular atrophy. The arrest of the primary growth, the disappearance of the bone metastases, and the dramatic amelioration of the symptoms are now a familiar experience to anyone who has treated such cases with oestrogens.

More recently, isolated reports have appeared indicating that administration of androgens in high doses and over long periods leads to a regression of breast cancers, with relief of symptoms and disappearance of radiological evidence of bone metastases in the younger group—i.e., of patients under 60—whereas oestrogens are reported to produce similar results in the older age group. It should be emphasized that there is no evidence of cure in any of these cases, and that after a period of anything from a few months to as long as five years there is a recurrence of symptoms with renewed activity of the primary growth and reappearance of metastases.

The mechanism by which this amelioration is produced is quite unknown. It may well be due to inhibition of the gonadotrophic influence of the pituitary on the gonad, and in this connexion it is interesting to observe that similar results have been claimed for surgical castration both in the male with carcinoma of the prostate and in the female with cancer of the breast. Some intrepid surgeons have even gone to the length of suggesting partial extirpation of adrenal cortical tissue in order to deprive the patient as completely as possible of the ipse-sexual sex hormone. It has also been suggested that carcinoma of these secondary sex-tissues can flourish only in an environment of normal or unduly prolonged sex-hormone secretion, and that by flooding the system with the contrasexual sex hormone this normal sex hormone pattern is disturbed, with arrest of the progress of the malignant condition.

The Protein-anabolic Effect of Androgens

Of the multiple excretion products of adrenal cortical activity (54 have so far been identified) three main groups have been classified. The first, which is exemplified by deoxycortone, controls water and electrolyte metabolism, and lack of this factor is mainly responsible for the symptoms of Addison's disease. A second group, the glyconic corticoids or 11-oxysteroids, is responsible for the conversion of protein precursors to glycogen, and is referred to as the S-hormone ("sugar" hormone) by Fuller Albright. There is evidence of excessive secretion of this hormone in Cushing's syndrome, which is usually accompanied by excretion of high concentrations of 11-oxysteroids in the urine. Albright seeks to explain the osteoporosis so characteristic of this condition on the theory that the conversion of protein to glycogen is selective and denudes the protein matrix of the bone on which subsequent calcification normally occurs. Other tissues selectively affected by this protein deficiency in Cushing's syndrome are, according to Albright, the skin, which becomes thin and atrophic as seen

pically in the legs and distal portions of the arms, and a peripheral blood vessels, which rupture easily and account for the bruises, ecchymoses, and "petechial haemorrhages." The third group consists of substances identified in the urine as the neutral 17-ketosteroids, which include all the adrenal androgens. According to Albright these are the substances responsible for nitrogen retention, and he refers to the group as the N-hormone ("nitrogen" hormone). S-hormone and N-hormone are mutually antagonistic, in so far as the latter is protein-anabolic and the former "anti-anabolic." Thus the effects of excessive S-hormone production, which depletes protein storage and leads to muscle wasting and weakness (as seen typically in Cushing's syndrome in the atrophy of the muscles of the buttocks and thighs), are similar to those due to deficiency of N-hormone, as indicated by lowered 17-ketosteroid excretion. The conditions associated with lowered or absent 17-ketosteroid excretion are pan-hypopituitarism (true pituitary infantilism and Simmonds's disease), eunuchoidism, Addison's disease—especially in women, though in men testicular androgens account for some degree of 17-ketosteroid excretion—and myxoedema. In all these disorders therapeutic administration of androgens leads to beneficial effects, though to a varying degree. Perhaps the most remarkable changes are seen in Simmonds's disease, in either sex, where an implantation of four to six 100-mg. pellets of testosterone overcomes the characteristic muscular weakness and is followed by an appreciable gain in weight, with increased muscular development and a positive nitrogen balance. In eunuchoidism there is also an increase in weight and muscular strength. In Cushing's syndrome the administration of androgens has been reported to have cured the osteoporosis. The therapeutic applications of this concept of the protein-anabolic action of androgens are still largely in the experimental stage, but it seems to be true in a general way that where the 17-ketosteroid excretion is low there is a tendency to muscular atrophy and weakness, and where it is high there is nitrogen retention and increased muscular strength. For instance, the "infant Hercules" with a prepubertal adrenal cortical tumour is not only bulging with muscle but is also abnormally strong.

Conclusion

The object of this paper has been to provide a brief account of the modern trends in sex-hormone therapy, with an attempt to rationalize the principles involved. It has not been possible to do more than wipe the dust off the cover of this rapidly expanding loose-leaf volume in the encyclopaedia of modern therapeutics. No references to original work have been cited, for such writings have not been consciously referred to. In holding myself responsible, therefore, for the views herein expressed I must run the risk of perpetrating such errors, both of omission and commission, as commonly accompany the necessarily dogmatic oversimplification to which a postgraduate lecture lends itself.

The West of England Child Health Group was formed in March, 1948, to foster co-operation between doctors and others who are concerned in the various aspects of child health. At the first meeting Professor A. V. Neale and Professor R. H. Parry opened a discussion on "The Integration of the Preventive and Curative Aspects of Child Health." At subsequent meetings, which are held at monthly intervals, discussions have taken place on a wide range of subjects, including gastro-enteritis, thoracic surgery, and upper respiratory disease. During the present session, 1948-9, the group has held a discussion on orthodontics and a clinico-pathological conference on mongolism. Dr. William Hobson (professor-elect of social and industrial medicine, University of Sheffield) gave an address on "Social Medicine."

ALTERNATING ORTHOSTATIC HYPOTENSION AND HYPERTHYROIDISM OF PROBABLE HYPOPHYSIAL- HYPOTHALAMIC ORIGIN

BY

F. VEGA DIAZ, M.D.

(From the Cardiological Department, Madrid General Hospital)

No final conclusions can be drawn from the following report, since considerations based on a single case lack sufficient foundation and must always be hypothetical.

Case Report

The patient, a married woman aged 24, was sent for examination of her circulatory system. Her father died at the age of 57 from a liver disease, her mother is alive and well, aged 57, and three brothers are also alive and well. One brother died at the age of 9 months, from an unknown cause.

Personal History.—Birth and early development were normal. She had measles and whooping-cough in early childhood, without complications, and very frequent attacks of sore throat, and has always suffered from constipation, anorexia, and asthenia. Menarche was normal, at the age of 14, with a normal menstrual cycle. From the age of puberty onwards, and for several years, she has suffered from dizziness. Perspiration has always been scanty. Immediately after menarche she found that on getting up after lying down for some time she always had a sensation of mistiness and progressive loss of vision, and a feeling that she was going to faint; she had to take hold of something quickly and sit or lie down again. These phenomena sometimes progressed to actual fainting, and appeared at odd times totally unconnected with the taking of meals or fasting.

These symptoms persisted until soon after her marriage at 22 and improved immediately afterwards, though at this time she was very nervous, suffered from palpitations, became thinner, and developed a slight swelling in the neck. She became pregnant six months after marriage. At that time the dizziness had disappeared; but, simultaneously with pregnancy and when the attacks of dizziness were becoming less frequent, there appeared other phenomena of endocrine origin: loss of weight—progressive though not excessive and less marked than before—trembling, and bad temper (she always had a certain tendency to depressive neurosis). The slight goitre persisted, and there was some fever, with attacks of palpitation and paroxysmal tachycardia. Her usual pulse rate was 90-100, and she sweated at night.

This syndrome was considered to be due to focal sepsis in the tonsils, and in the third month of pregnancy they were removed. In spite of this the neurosis persisted and the paroxysms of tachycardia continued. At this time the slight thyroid enlargement was noted and the basal metabolism was found to be +28, and a month later -37.

A corrected diagnosis of gestation hyperthyroidism was made, and treatment with methyl thiouracil was prescribed, but the patient did not notably improve, the B.M.R. remaining unaltered. She then had a normal confinement but did not nurse her baby. The slight hyperthyroidism continued. Treatment with methyl thiouracil, alternating with Lugol's solution, was now instituted and the signs and symptoms of hyperthyroidism disappeared. She put on weight, though not enough to compensate for the previous loss: the thyroid became normal in size and the attacks of tachycardia gradually disappeared. Surprisingly enough, however, just as she was recovering from the hyperthyroidism and was getting well again, she noticed a return of the postural dizziness—i.e., the orthostatic hypotension syndrome reappeared after having been latent, or having disappeared, during the phase of hyperthyroidism.

Clinical Examination.—The patient was of asthenic constitution, with dry skin, waxen pallor, and prominent superficial veins. The mouth was healthy, without dental sepsis. The lungs were normal. The heart was normal on palpation and percussion. Cardiac sounds were lively but normal, and the pulse

was soft, compressible, and of normal frequency and rhythm. Arterial pressure in the right arm, in sitting posture, was 90/50, pulse rate 80. Without being able to make her rest beforehand, we took her arterial pressure in a vertical posture, when the figures dropped slightly to 80/40, with pulse rate 84.

On finding such low pressures and confirming our clinical impression that her dizziness was due to postural hypotension we proceeded to examine her orthostatic reactions on a tilt-table. After ten minutes' rest in the horizontal position the B.P. was 90/50. On changing rapidly to the vertical the successive pressures were: immediately after the change, 95/60; and 30 seconds later 60/40. 60 seconds later still the pressure dropped to about 40, and auscultation revealed sounds only in the region of 45 and 35 without our being able to determine accurately the systolic and diastolic pressures—i.e., without pulse pressure. The patient now had a sudden sensation of weakness and dizziness and became very pale, but without any sweating and without any noticeable change in the pulse rate on auscultation. The phenomena became more pronounced until, a little before two minutes had passed, the patient fainted, and only some very soft sounds were audible around 30 mm.; but, in view of the alarming circumstances of the moment, we could not study the pulsation index on the oscillometer, which had previously dropped from 20 to 10 mm. The patient was placed supine slightly tilted in the Trendelenburg position, and was given rapid passive movements of the limbs with centripetal massage. She quickly recovered, her blood pressure rising progressively to 60/40, 80/40, 90/45, and 108/60—i.e., to a figure slightly above the initial one. Sinocarotid sensitiveness and eye-compression tests were made, and proved negative, there being not even a fall in pressure or bradycardia, or syncopal or presyncopal phenomena of a cerebral type.

Pre-carotid pressure (according to Engel's technique), applied to ascertain whether the case was one of elective derangement of the cerebral circulation, gave completely normal results. An atropine test (2 mg. given intravenously) did not prevent a certain amount of postural reaction; neither did it produce a sufficiently high tachycardia; but we must point out that the slight atropine tachycardia was enough to substitute a simple dizziness for the postural fainting, although the arterial pressures had dropped in the same way as happened without atropine: a compensating effect through increase in the minute-volume. Valsalva's and Flack's tests produced syncope even at 45 degrees on the tilt-table.

Investigation revealed:—Abdomen: flaccid, no tender points; neurological examination quite normal; special senses, normal. The arm-to-tongue circulation time was 17 seconds (decholine) and the arm-lung time 8 seconds (ether). X-ray examination of the chest revealed a normal vertical heart, with normal outlines in all positions.

In the electrocardiogram the complexes were normal in all the leads and of the vertical heart type. Other curves in the vertical posture showed rather the phenomenon of a "hanging heart" and, furthermore, noteworthy alterations of the S-T intervals; in the first curve in the vertical position S-T2 was depressed, but there was still a positive T wave and the T3 wave became more negative. In the second curve, taken after 90 seconds, the T2 wave became negative and was preceded by a somewhat curved previous interval. Among the other data we also observed a shortening of the electrical systole and high and ample P2 waves that were not seen in the horizontal posture.

The blood picture was almost normal; there was slight macrocytic anaemia (average cell diameter 8.10μ), with normal leucocyte count and distribution. Total plasma proteins, 6.9%, with an albumin-globulin ratio of 1.03. Cholesterol, 120 mg. per 100 ml.

Test meal, normal. By duodenal drainage, bile was extracted in which a *Proteus* organism was cultivated; in the faeces, Type 1 *Bact. coli* was cultivated as well as the *Proteus*. Ophthalmic examination showed only a slight vascular invasion of the limbus (Dr. C. Costi). X-ray examination of the digestive system (Dr. E. Castillo) revealed an enteropathy of the small intestine with marked colonic atony; cholecystography revealed the gall-bladder, but it showed no emptying. Finally, the basal metabolic rate was normal: +6%.

Discussion

This syndrome corresponds exactly to that of orthostatic hypotension syncope. The differential diagnosis would have to exclude the other syncope that are more or less related to the vertical position, and especially the so-called vasodepressor syncope. The direct and invariable relation to the vertical position and the abrupt fall of blood pressure are sufficient for exact diagnosis. The absence of sweating and the fact that the orthostatic hypotension syncope have never been produced by other stimuli (emotion, trauma, etc.) differentiate them from neurogenic or psychogenic vasodepressor syncope; it is evident, therefore, that the present case is not the kind of vasodepressor syncope observed in the processes of infectious diseases, heart-shock, etc.

The negative result of pressure on the carotid sinuses (examined successively and conjointly) and on the eyeballs rules out the reflex and vagus factor. Atropine, though it slightly raised the heart rate (from 80 to 90) and prevented total orthostatic syncope, could not prevent a feeling of dizziness and loss of vision, which the patient remedied by moving her limbs as she was ordered—a manoeuvre that was less quickly effective in total syncope. This proves that the syncope was not of the orthostatic vasodepressor type of sinocarotid origin and that the vagus factor was secondary. Neither is it a case of reflex or arrhythmic cardiogenic syncope, since there are no electrocardiographic data of alterations of the intracardiac conduction of the electric stimulus, nor any extrasystoles or other signs leading one to suspect a cardio-irritative syncope (of paroxysmal tachycardia type). The electrocardiographic anomalies observed in this patient are very typical of orthostatic hypotension; they have been related to postural coronary insufficiency (Åkesson, 1936; Meesen, 1937) and to a heightening of the sympathetic tone (Nordenfelt, 1941, 1942), but they are not so marked that the attacks of dizziness affecting the patient can be ascribed to them nor can they be related to "coronary shock" (Bezold type).

The history and the neurological examination exclude all possibilities of a neurological lesion being responsible for the orthostatic hypotension (tabes, syringomyelia, etc.) Other processes that generally give rise to orthostatic hypotension (pituitary insufficiency, adrenal insufficiency, etc.) were not found here either. Therefore there can be no question of a secondary orthostatic hypotension.

By exclusion, a diagnosis of syncopal disease due to *chronic essential orthostatic hypotension* (Pont, 1945) was made.

We may observe that during adolescence and puberty the patient developed a syndrome of postural hypotension, very rare at this age, since practically all the cases of orthostatic hypotension syndrome recorded were in persons over 50 years of age, and this is not the classical "orthostatic vasoneurosis of second childhood" described by Seckel.

When the patient was married, and particularly in the nuptial phase, her postural troubles disappeared at the same time as a slight hyperthyroidism syndrome set in. It is therefore evident that her hyperthyroidism, which is not of Basedow type, caused circulatory changes sufficient to lessen or even suppress the postural syndrome and to cause the subjective symptom of postural dizziness to disappear in spite of the persistence of hypotension from which the patient says she suffered throughout pregnancy.

It is evident, as Maraño (1947) and others have recently insisted, that the genetic basis of these types of hyperthyroidism must be sought, probably in an organic or humoral disturbance of the kind now called hypophyseal hypothalamic block. The nuptial-phase hyperthyroidism

ving to the emotional characteristics attributed to it, enters into this syndromic group for two reasons—its discrete character with mild hypermetabolism, the emotionalism, over, slight resistance to medical treatment, the increase in weight during treatment without entirely regaining the weight previously lost, and the absence of adenomatous pituitary all characterize it as hypophysis-hypothalamic, according to Marañón's latest revision.

On the other hand, it is well known—and I have dealt with this elsewhere—that the mechanism underlying the orthostatic hypotension syndrome may also be based on hypothalamic physiopathological factors. From time to time investigators have described successive hyperpressor and hypopressor centres of the hypothalamic region, culminating in the recent work of Hess (1946) with a relatively accurate location of such centres in experimental animals. Essential orthostatic hypotension in Pont's sense—i.e., including orthostatic hypotension secondary to other processes (endocrine, Addison's disease, Simmonds's disease) or diseases of the central nervous system (tabes dorsalis, etc.)—is the result of an associated series of factors causing sudden reduction of the heart minute-volume on assuming vertical posture.

In hyperthyroidism the peripheral vasomotor tone is really increased whether or not there is any degree of capillary dilatation (in this case, indicated by the fever and sweating). The regional pooling of blood is difficult owing to the increase in quantity and speed of the blood circulating through the tissues. Although pregnancy did not improve the digestive atony in this patient, the mesenteric accumulation (also accentuated by colitis) may have been reduced during the phase of hyperthyroidism. The hypotonia of the skeletal muscles may also have been counterbalanced by the increase of muscular activity caused by the hyperthyroidism which is observable in the muscular tremor of cases of hyperthyroidism. Finally, the faulty regulation of the cardiac output in orthostatic hypotension—i.e., the lack of cardiac adaptation to inflow reduction, lack of compensating tachycardia—is here overcome by the real increase of the minute-volume characteristic of hyperthyroidism, which in this case was further conditioned by the permanent tachycardia. We may consider that the hypothalamic disturbance which produces the hyperthyroidism is directly related to the hypothalamic disturbance which conditions the orthostatic hypotension and the digestive atony, and even that the tachycardia and the attacks of paroxysmal tachycardia were not of direct endocrine origin but were due to an irritating affection—possibly hormonal—of the sympathetic nuclei of the hypothalamus.

Summary

A clinical case is described in which a juvenile orthostatic hypotension syndrome with orthostatic syncope was followed by a slight nuptial hyperthyroidism accentuated during pregnancy, at which time the orthostatic hypotension disappeared only to reappear when the former was cured by antithyroid medication.

A hypothalamic origin is ascribed to both syndromes and the hyperthyroidism and the attacks of paroxysmal tachycardia are explained as a teleological mechanism of defence in the gestation period.

ORAL REACTIONS TO PENICILLIN

BY

W. G. CROSS, M.B., M.S., B.D.S.

Department of Periodontia, Institute of Dental Surgery,
Eastman Dental Clinic

In the second half of 1946 several cases of reaction to penicillin used locally in the mouth had been reported and these, together with the occasionally unsuccessful results of penicillin therapy in oral infections, led to the investigations which gave rise to this paper, and which were carried out in the Dental Department, Guy's Hospital, in 1947, as the subject of the Ernest Hart Memorial Scholarship of the British Medical Association.

A review of the literature up to the end of 1947, when the investigations were concluded, reveals a limited number of cases of reaction to penicillin. Bedford (1946) describes two cases of black tongue occurring in patients treated with pastilles and lozenges for three days on the one hand and pastilles and spray on the other. The discoloration appeared on the fifth and fourth days and cleared in 13 and 12 days respectively. Thompson (1946) describes glossitis arising from penicillin lozenge therapy in three patients suffering respectively from tonsillitis, pharyngitis and aphthous ulceration. Different batches were used in all three cases.

Cameron (1946) reports two cases of stomatitis occurring after four to five days' treatment with 50 lozenges. Murphy (1946) describes a case of stomatitis occurring after two days' treatment. Bradlev (1946) inhaled penicillin spray—total dosage 800,000 units in first 10 days, then 1,000,000 units during the next five days. He developed soreness and dryness of lips and nostrils and a sore tender tongue.

Ellinger and Shattock (1946) report the case of a woman subject to attacks of nicotinamide deficiency in whom 15 penicillin lozenges, together with drops of a solution containing 500 units of penicillin per ml pipetted on to the tongue for five days, brought about a slate colour. They consider that the discoloration was due to pigmentation of the filiform papillae, and suggest that the penicillin thus taken is swallowed and passes through the stomach in sufficient quantity to inhibit the growth of intestinal organisms responsible for the synthesis of nicotinamide, and that the oral reaction was largely one of nicotinamide deficiency. In this connexion a number of patients treated by me were given lozenges containing 500 units of penicillin and 2 or 6 mg of nicotinamide, taken in the usual way, and about 20% of these patients developed a discoloured tongue.

Goldman (1946) describes a case of vesicular cheilitis in a patient treated thrice daily with a mouth-wash containing 500 units of sodium penicillin per ml of saline. A patch test was positive for sodium penicillin and negative for calcium penicillin.

Wright and Rule (1946) report 19 reactions among 189 patients treated with penicillin lozenges. Of these six occurred among 38 patients on calcium penicillin lozenges and 13 among 151 patients on sodium penicillin lozenges. They consider the sodium salt to be less toxic.

Blyth (1947) describes a case of glossitis following the use of penicillin lozenges for four days that recovered in three days. Ackers (1947) reported reactions in 49 patients treated; four had discoloured tongues, which took three weeks to resolve, one had glossitis, and one was able to taste penicillin four days later.

Reactions to Penicillin

A total of 59 cases of oral reactions to penicillin have been studied in this investigation—36 from the literature, 12 reported in personal communications, and 11 observed personally. The two common conditions are discoloration of the tongue and stomatitis—in the latter condition glossitis being marked.

Discoloration of the tongue is the commoner condition. It occurs in at least 30% of patients taking penicillin continuously for oral conditions. It is often unnoticed by the patient, and is not accompanied by any symptoms of discomfort. Only one case was reported where discoloured tongue and stomatitis coexisted. Discoloration begins two to four days after starting treatment and wears off in five to 14 days. It consists of a pigmentation of the filiform papillae, and is most pronounced in the central furrow and towards the back; it may be yellowish brown, brownish green, greenish black, or black. It is absent at the sides and tip of the tongue.

—the normal fur having been lost in a patchy manner—with bright-red prominent fungiform papillae. The tip especially is affected.

Table I shows the cases reported to me and Table II the cases I saw personally. Among the latter those whose condition is indicated as "normal" were volunteers.

Some of these cases were treated with penicillin incorporated in chewing-gum—10,000 units per portion of gum. It was shown by McIntosh and Perryman (1946) that the gum would still be capable of liberating penicillin after as long as six hours, and this method of treatment was found of great use. Dosage was reduced to one portion of gum thrice daily, and this simplified treatment was highly effective in the acute stage of ulcerative gingivitis.

Cause of Penicillin Reactions

Suggestions on the causation of glossitis and discoloured tongue have been varied. The base of the commercial trochiscus penicillini, B.P., has been incriminated (Ingram,

TABLE I.—Cases Reported in Personal Communications

Case No.	Condition Treated	Reaction and Onset After Starting Treatment	Remarks
1	Pharyngitis	Cheilitis, glossitis, black tongue	Occurred on two occasions, using two different makes of lozenge
2	Not stated	Glossitis	
3	Haem. strep. sore throat	Erythema of palate, tongue, and pharynx after 3 days. Ageusia for 3 weeks	No cutaneous reaction to lozenge applied to skin of forearm
4	After extraction of incisors	Dark patches on tongue, absence of salivation, discomfort in deglutition after 3 weeks	Lozenges and pastilles
5	Inflammation of palate	Glossitis after a few days—red, swollen tongue with enlarged papillae	Powdered penicillin lozenges over upper denture
6	Coryza	Glossitis on 3rd day (20 lozenges for 2 days), tongue and fauces reddened; detachable brown fur. Two days later extensive stomatitis	Taken to prevent secondary infection from a cold. <i>M. albicans</i> present
7	"Gum condition"	Dark sepioid tongue on 5th day (lozenges for 3 days). Wore off in 4–5 days	
8	Pharyngitis	Black mould-like growth (onset not stated). Had only 3–6 lozenges in one day	This was repeated three times
9	Dry socket after extraction	Stomatitis after 9 days' treatment. Brownish-black tongue 10th day. Lozenges taken 11 days in all	
10	Pharyngitis	Black tongue. 40–50 lozenges taken in 3–4 days	
11	Infected socket	Brown tongue after 7 days. 35 lozenges in 10 days	
12	Ulcerative gingivitis (Vincent's)	Black tongue after 4–5 days. Cleared in 7 days	

TABLE II.—Cases Observed Personally

Case No.	Condition	Reaction and Onset After Starting Treatment	Micro-organisms
1	Infected socket	Brown tongue (4th day)	<i>Ps. pyocyanea</i> , Friedländer's bacillus
2	(1) Normal (standard 500 unit lozenge) (2) Normal (500 unit lozenge with 2 mg. nicotinamide) (3) Normal (crystalline penicillin, 500 units)	Greenish-black tongue (4th day) Brown tongue (3rd day, lasted 9 days) Brownish-green tongue (3rd day)	<i>M. albicans</i>
3	(1) Normal (500 units penicillin) (2) Normal (crystalline penicillin, 500 units)	Stomatitis; very sore tongue (6th day, lasted 5 days) Stomatitis (5th day, lasted 7 days)	" "
4	Normal	Glossitis (4th day)	
5	Infected socket	Brown tongue (4th day)	<i>Staph. albus</i> , <i>M. albicans</i>
6	Acute ulcerative gingivitis	Brown tongue (3rd day)	<i>Proteus vulgaris</i>
7	Acute ulcerative gingivitis	Greenish-black tongue (5th day)	
8	Pharyngitis	Nausea on 3rd day, glossitis on 5th day, lasted 7–10 days	
9	Pharyngitis	Brownish-green tongue (5th day)	
10	Extraction of 21	Black tongue (3rd day); had 25 lozenges in 48 hours	<i>N. catarrhalis</i> . Anaerobically a coliform bacillus. No fungi or yeasts
11	Acute ulcerative gingivitis	Brown tongue	

Attempts were made without success to determine the nature of the pigment. Scrapings from discoloured tongues were examined microscopically. Dark pigment was observed in the epithelial cells of the filiform papillae, but owing to failure to get enough pigment into solution spectroscopic analysis was not possible. In no cases were chromogenic bacteria or fungi detected, although *Monilia albicans* was present in several.

Penicillin Stomatitis

In a typical case the patient, who has been treated for three to five days with topical penicillin for some oral or pharyngeal condition, complains of marked soreness of the tongue and at times of the whole mouth and pharynx, with extreme discomfort on taking hot fluids, spiced foods, and condiments, or on smoking, and occasionally ageusia and lack of salivation. The condition lasts six to ten days, but the loss of the sense of taste may last some weeks. Examination in the acute stage shows a swollen red tongue

(1947). Ellinger and Shattock (1946) suggested that the reactions may be due to nicotinamide deficiency. Penicillin administered as lozenges was swallowed, and inhibited the growth of intestinal organisms responsible for the synthesis of nicotinamide. In this connexion a number of the patients treated by me had two- or three-day course of penicillin lozenges containing 2 mg. of nicotinamide, and in many of those so treated discoloured tongues developed.

Other possibilities are: (1) the presence of penicillin insensitive organisms, with the absence of the normal flora and (2) individual sensitivity to one or more penicillins or impurities. The possibility of the lozenge base being responsible, either chemically or mechanically, was the subject of much investigation.

All penicillin used commercially is produced by a limited few companies; this penicillin is then marketed by a large number of firms. Clinical trials were made with lozenge produced by seven firms. The compositions of the base of

The lozenges were made known by the makers. The lozenges were made in accordance with the *British Pharmacopoeia* recommendations on penicillin—namely, that each lozenge should contain 500 units of calcium penicillin in a sucrose or sucrose and lactose base. In most cases gum tragacanth was present, about 3–8%, magnesium stearate 0.8–2%, and flavouring agents—e.g., vanillin, essence of lime—in small amounts. All these are substances used in common pharmaceutical practice, and it was felt unlikely that any of them would cause a toxic reaction. As a test of this, lozenges consisting of the base only (blanks) were given to a number of patients, including several who had had glossitis or discoloured tongue with the penicillin lozenges previously. Though the blanks were given for several days, in no case did they produce any toxic effects. { }

Finally, reactions have been reported when penicillin has been administered in other forms—e.g., inhalation of nebulized aqueous solutions (Mutch, 1947) and continuous intratracheal drip (Royston, 1947). In addition, both types of reaction were observed in patients treated with crystalline G lozenges and pastilles; these contained about 96% of penicillin G, 4% of the other penicillins, and no impurities.

In many cases of reaction to penicillin the mouth cavity, as tested by the salivary count, was either sterile or contained coliform organisms. In a number of cases, however, *Pseudomonas pyocyanea*, Friedländer's bacillus, *Proteus vulgaris*, and *M. albicans* were present. From the two tables it will be seen that the average reaction to penicillin began on the fourth day of treatment, but sometimes did not begin for seven or even nine days. In most cases treatment had been carried out for three or more days—i.e., beyond the point (48 hours) where the oral flora had changed completely to penicillin-insensitive organisms. Symptoms usually diminished in two days from the time of ceasing penicillin therapy, but persisted to a lesser degree for about a week, and occasionally longer.

Of the less common symptoms, lack of salivation, ageusia, and a capacity to taste penicillin after cessation of treatment are the most striking.

Summary and Conclusions

A review of the reported cases of oral reaction to penicillin used locally in the mouth is given, together with an account of similar cases among patients treated in the dental department at Guy's Hospital.

Neither nicotinamide deficiency nor the lozenge base is responsible for these oral reactions.

It is noticed that reactions do not occur until there has been a complete change in the character of the oral flora. This takes about 48 hours, and it seems reasonable to limit the use of penicillin for the treatment of oral infections to this length of time as a rule. To maintain an adequate and continuous concentration of penicillin in the mouth the use of this antibiotic in chewing-gum, 10,000 units per piece, thrice daily, is suggested.

I would like to thank Dr. C. Shuttleworth, assistant dental bacteriologist, for numerous salivary counts and helpful advice; the many dental students who so kindly co-operated in this investigation; and Mr. Gott, of the dispensary, for overcoming the technical difficulties inherent in the preparation of penicillin chewing-gum.

CARRIAGE OF PENICILLIN-RESISTANT STAPH. PYOGENES IN HEALTHY ADULTS

BY

T. D. M. MARTIN, M.R.C.S., L.R.C.P.

AND

J. E. M. WHITEHEAD, M.A., M.B., B.Chir.

(From the Department of Bacteriology, St. Thomas's Hospital Medical School)

The number of papers on this subject that have appeared in recent years indicates that there may be an increase in resistance to penicillin among strains of *Staph. pyogenes* isolated at different times from human infections during the course of penicillin treatment (Rammelkamp and Maxon, 1942; Anderson *et al.*, 1944; Bondi and Dietz, 1945; Gallardo, 1945; North *et al.*, 1946). On the other hand, there is also evidence that strains of *Staph. pyogenes* exist which are naturally resistant to penicillin, having been isolated before the institution of penicillin treatment and in many instances having been shown to possess the power of inactivating penicillin by the production of penicillinase (Kirby, 1944; Spink *et al.*, 1944a, 1944b; Bondi and Dietz, 1945; Gots, 1945; Gallardo, 1945; Harley *et al.*, 1946).

Further, it has been shown by Barber (1947a, 1947b) that the incidence of infection with penicillin-resistant strains may be increasing, since in one hospital the percentage rose from 14.1 in 1946 to 38 in 1947. There is thus evidence not only that some strains of *Staph. pyogenes* are resistant to penicillin and that some may become resistant in the course of treatment but also that the incidence of infections with such strains may be increasing.

The nose and skin of normal persons have been shown by many earlier workers to be reservoirs of considerable importance for the carriage of potentially pathogenic staphylococci (for studies and references to earlier work see the papers of Miles *et al.*, 1944; Williams, 1946).

Investigations of outbreaks of staphylococcal infections have shown that the nose, throat, and skin of persons in the patient's environment, or of the patient himself, harboured strains of the same phage or serological type as the infecting strain (Allison and Hobbs, 1947; Hobbs *et al.*, 1947).

So far as we are aware there has been no published work concerning the incidence of penicillin-resistant strains of *Staph. pyogenes* occurring in the nose and throat and on the skin of normal persons, although Moss *et al.* (1948), in an investigation in 1946, encountered one resistant strain and one partially resistant strain in the noses of 21 patients who were persistent nasal carriers of *Staph. pyogenes*.

In view of the evidence in support of the nose and skin as reservoirs of strains able to cause infection, it is obviously important to investigate the incidence of strains resistant to penicillin in these situations. Opportunity was taken, therefore, to examine the penicillin-resistance of all coagulase-positive strains of staphylococci isolated from the nose, throat, saliva, and six skin sites of 50 healthy individuals during the course of a different investigation.

Following the practice of earlier workers, we have applied the term *Staph. pyogenes* to all coagulase-positive staphylococci irrespective of pigmentation.

Isolation of Strains

The group, studied between April and November, 1947, consisted of 50 volunteer male medical students and laboratory workers. One-half of these were students not engaged

in clinical work and laboratory staff not primarily handling material likely to be infected with *Staph. pyogenes*. None of the volunteers was infected clinically.

Nine sites were swabbed in the following manner:

Throat.—A dry cotton-wool swab was rubbed over the tonsils and the posterior pharyngeal wall.

Nose.—A swab moistened with broth was passed into both anterior nares.

Saliva.—A dry swab was dipped into a pool of saliva allowed to collect between the gum and lower lip.

Skin.—This was sampled on the following six sites by rubbing a swab moistened with broth over an area the size of a penny with a circular motion 20 times: (1) *Face*: both malar prominences. (2) *Hand*: palmar surface of the right hand. (3) *Chest*: middle third of the sternum. (4) *Abdomen*: immediately above the umbilicus in the midline. (5) *Back*: over the lumbar vertebrae. (6) *Leg*: over the right patella.

All swabs were immediately inoculated into "lemco" broth and incubated aerobically overnight. The following day subcultures were made from the broth on to horse-blood-agar plates, which were then incubated overnight and examined the next day for colonies of staphylococci. Where there were any differences—e.g., in pigmentation, presence or absence of haemolysis, etc.—representative colonies of each variety were picked. The colonies thus picked off were subcultured on to segments of a lemco-agar plate and incubated overnight. Films were made the next day and stained by Gram's method, and strains which did not show the typical morphology of the staphylococcus were discarded. The plates were allowed to remain on the bench for three days to enable pigment production to be recorded, and the strains were then subcultured into agar "stabs" and stored at 4° C. A total of 340 strains were isolated.

All strains were then examined for the production of coagulase, using the tube technique as described by Gillespie (1943). This test was used as the sole criterion of potential pathogenicity, as earlier work has shown it to be the simplest and most reliable single test for pathogenicity among staphylococci. Of the 340 strains examined 83 (24.4%) were found to be coagulase-positive.

Carriage of *Staph. pyogenes*

The details of carriage of the 83 strains of *Staph. pyogenes* among the 50 individuals are shown in Table I.

TABLE I.—Carriage of *Staph. pyogenes* Among 50 Healthy Adults

Site of Carriage	No of Carriers	% of Whole Group	% of 31 Carriers
Nose	20	40	64.4
Throat	9	18	29.0
Saliva	2	4	6.4
Face	14	28	45.1
Hand	7	14	22.5
Chest	9	18	29.0
Abdomen	7	14	22.5
Back	2	4	6.4
Leg	4	8	12.8
No. of carriers	31	62	
Nose or throat only	10	20	32.2
Skin only	7	14	22.5
Combined nose or throat or saliva and skin	14	28	45.1

On each of nine sites in five individuals there were isolated two different strains of *Staph. pyogenes* as judged by colonial appearance.

The findings shown are similar to those of Williams (1946), who surveyed a comparable group of 50 students by sampling the nose only, together with 11 skin sites, using somewhat similar cultural methods. There is, however, some disparity between our findings and those of Williams concerning the prevalent site of carriage in those

who are not simultaneous nasal and skin carriers. In our series, of the 17 persons from whom *Staph. pyogenes* was isolated from either skin or nasopharynx, but not from both, in 10 (58.8%) the organism was found in the nasopharynx only and in 7 (41.2%) on the skin only. Williams however, found among 19 such persons that only 3 (15.7%) were nasal carriers, while 16 (84.3%) were skin carriers.

The numbers examined in both series are small and the discrepancies are possibly due to the fact that Williams examined 11 skin sites but not the throat and saliva, whereas we studied six skin sites but also examined the throat and saliva.

Penicillin Resistance

The 83 coagulase-positive strains isolated in the above investigation were next examined for penicillin resistance using in the first instance the ditch-plate method with a concentration of 10 units of penicillin per ml. of agar in the ditch: 15 strains (18%) were found to be resistant by this method.

These strains were next retested by the serial dilution method in broth, using serial dilutions of penicillin in 0.5-ml. amounts of broth. The inoculum was one drop (0.02 ml.) of a 1 in 100 dilution of a 24-hour broth culture. Our results are shown in Table II.

TABLE II.—Degree of Penicillin Resistance

No. of Times More Resistant than the Oxford Staphylococcus	No. of Strains
128	4
64	1
32	6
16	3
8	1
Total	15

The 15 resistant strains were carried by six members of the group studied. One of the six subjects (REE) was found to be carrying on a number of sites two strains of *Staph. pyogenes* differing in their colonial appearance. One strain (R2), occurring on two sites, had a resistance 12 times that of the Oxford staphylococcus, and the other (R1), occurring on three sites, had a resistance 32 times greater than that of the Oxford strain. It is impossible without the help of methods of identification, such as serological or phage typing, to decide whether these two apparently different strains are in fact different or whether they represent mutants from a single parent strain.

Only one (LUM) of these six persons had ever had penicillin treatment; he once had some penicillin lozenges. Details of the carriage are shown in Table III.

TABLE III.—Carriage of the Penicillin-resistant Strains Isolated

Carrier	Sites								
	Nose	Throat	Saliva	Face	Hand	Chest	Abdomen	Back	Leg
SAY	R	—	—	R	—	—	—	—	—
LUM	S	—	—	S	S	R	R	—	—

REE	R1, R2	R1, R2	—	R1	—	—	—	—	—
COR	—	—	—	R	—	—	R	R, S	S
BES	R	R	—	—	—	—	—	—	—
No of carriers	3	3		3		1	2	1	

The carrier rate of resistant strains among 50 healthy adults is 12%, that among 31 healthy carriers of *Staph. pyogenes* 19.4%.

R = Resistant strain
S = Sensitive strain of *Staph. pyogenes*.
R1 and R2 = Strains isolated from same individual with marked differences in degree of resistance.

Discussion

In the 50 healthy adult males investigated the rate and distribution of carriage of *Staph. pyogenes* were similar to those found by earlier workers in groups of healthy

adults. The foregoing observations are comparable to those reported by Williams (1946) in a group of the same number and of similar occupation.

Of the group of 50 persons, 6 (12%) were carriers somewhere on their persons of strains of *Staph. pyogenes* resistant to penicillin. This comprises nearly one in five, or 19.4%, of the 31 persons who were carriers.

These figures are disturbingly high, although not perhaps unexpected in view of the apparently increasing incidence of penicillin-resistant strains in human infections. We are, however, not in a position to assess whether there has been an increase in the carrier rate of resistant strains comparable to that found in the incidence of strains isolated from infections, for we have not been able to discover any published work in this connexion. Moss *et al.* (1948), who were endeavouring during 1946 to abolish nasal carriage of *Staph. pyogenes* by the intranasal administration of penicillin to 21 patients who were persistent nasal carriers, encountered one case which yielded a penicillin-resistant strain and one case which yielded a partially resistant strain during the course of treatment. Neither of these strains, however, was able to produce penicillinase.

We are able to confirm the findings of others (Kirby, 1944; Bondi and Dietz, 1945; Gots, 1945; Barber, 1947a, 1947b) that these naturally occurring resistant strains are able to inactivate penicillin.

Summary

Swabs from the nose, throat, saliva, and six skin sites of 50 healthy men showed a carrier rate of 62% for coagulase-positive staphylococci.

Examination of the 83 coagulase-positive strains isolated showed that 15 (18%) penicillin-resistant strains were being carried by six persons (12%).

Among the 31 carriers of coagulase-positive staphylococci the carrier rate for resistant strains was thus 19.4%.

The resistant strains were all able to inactivate penicillin.

The significance of the findings is discussed.

Our thanks are due to Professor R. Hare for his valuable advice and criticism, and to the various medical students and laboratory workers of St. Thomas's Hospital Medical School for their co-operation in this survey.

The Scientific Film Association has issued a useful pamphlet entitled "On Organizing Medical Film Programmes" (price 1s. from the Association, 34, Soho Square, London, W.1). Notes on such practical details as how to arrange the chairs, making sure that the fuses are readily accessible, providing a firm table for the projector, and choosing colour or monochrome films are included, and there is a short summary of the law in relation to showing films.

INFECTED HANDS TREATED WITH SYSTEMIC PENICILLIN

BY

GORDON A. BARCLAY, F.R.C.S.

Formerly Demonstrator of Minor Surgery,
Out-patient Department, London Hospital

In an attempt to assess the value of systemic treatment penicillin was given as a routine to all out-patients attending the Infected Hands Clinic at the London Hospital from November, 1946, to January, 1948.

Method

Systemic Penicillin.—One intramuscular injection of penicillin, 200,000 units in aqueous solution (100,000 units per ml.), was given each day. The only variation in dosage was a reduction to 100,000 units in small children and a rise to 300,000 units for the first two or three days of a severe infection with systemic reaction.

Local Dressings.—Penicillin cream (500 units per gramme in an emulsifying wax and castor-oil base) was applied. Glycerin and magnesium sulphate paste was also used extensively in the presence of slough and during the course of systemic penicillin, local chemotherapy being of little value in the presence of necrotic tissue. Repeated saline or antiseptic baths were never used, but occasionally a hypertonic saline bath enabled one to remove a dry adherent dressing, drain, or scab under which pus was collecting. The drains were sterile ribbon gauze dipped in penicillin cream, which achieved the effect of local penicillin with the minimum of difficulty. Splints were never used except in cases of arthritis or tenosynovitis, because it was felt that the bulky dressing applied after incision, combined with a sling, gave adequate rest for the first 48 hours, and that after this time active movements were desirable. Dressings were done on an average every second day.

Physiotherapy.—No short-wave diathermy or dry heat was given. The great majority of patients did not attend the physiotherapy department. All cases with much sloughing of the pulp or osteomyelitis attended a class for finger exercises and occupational therapy.

Incision.—General anaesthesia—gas, oxygen, with occasionally "trilene"—was used, and in many cases an avascular field was ensured by a rubber tubing tourniquet round the base of the finger. Local nerve-block with procaine was employed occasionally. Ethyl chloride spray was not used.

The selection of alternate cases as controls being impracticable, the records of the previous six months are presented for comparison, as well as those of six months in 1944. The types of infection are dealt with below.

I. Paronychia

Surgery.—In early cases a unilateral incision was made in the angle of the nail fold. Usually the incision was bilateral, raising a dorsal flap and removing part or all of the nail according to the extent of the infection. A drain was left under the flap for 48 hours.

The results of treatment with penicillin are given in Table I.

Conservative Treatment.—For 12 out of 134 cases no incision was necessary, inflammation resolving with local heat and penicillin. The average length of history was 3.3 days (10 cases).

Operative Treatment.—Usually pus had already formed when the case was first seen. Incision was then necessary. A preliminary review of cases after 50 to 60 patients had

† Day of incision till full epithelization with separation of all crusts and scabs

been discharged showed little difference in the results in all but severe cases. It was therefore decided to omit systemic penicillin from the treatment of mild cases (Series III); these are compared with a larger group containing all cases treated with systemic penicillin, weighted by a larger proportion of severe cases (Series IV). Series III gave both longer incision-drying (I.H.) and admission-discharge (A.D.) intervals, which in the case of the I.H. interval would have occurred only 1 in 100 times, and in the case of the A.D. interval 1 in 33 times, through chance. Thus the milder cases, instead of showing shorter intervals as would be expected, gave slightly longer intervals. In comparing the "controls" with cases treated with systemic penicillin the difference is statistically significant for Series II, but though the difference is larger in Series I the greater variation gives a 1 in 25 possibility of the difference being due to chance.

II. Uncomplicated Terminal-pulp Infection

The results of the penicillin treatment of this series are given in Table II.

Surgery.—Hockey-stick or bilateral through-and-through incisions were made with division of all longitudinal fibrous septa in each case. The horseshoe or crocodile-mouth incision was not used, the functional end-result being poor.

Conservative Treatment.—In cases with a short history of pain (1-4 days) and only one or two nights' loss of sleep, and where on examination it was thought that pus had not yet formed, incision was delayed, systemic penicillin, kaolin poultices, and some analgesic being the only treatment. To these cases must be added a number in which there was some contraindication to immediate operation. Twenty-seven cases were treated in this way. Five of these resolved without pus formation and 22 had incision one or more days later (mean 1.64 days). The incision was often limited to part of the terminal pulp without division of all fibrous septa, as in many cases a well-marked localization had occurred within the terminal pulp and general swelling and tension of the pulp had subsided. As can be seen from Table II, all the intervals measured are shorter than in the main penicillin-treated group. The difference of 3.48 days

in the I.H. interval would have occurred only 1 in 100 times as a matter of chance; the significance of the other differences is less than this. The mean length of history in this group (No. 6) was only 3.0 days as compared with 4.27 for all cases (Group 3). This shorter history may be partly responsible for the quicker healing, but at least it seems clear that delayed incision did not delay healing and did not result in complications causing prolonged disability.

Operative Treatment.—Table II shows that penicillin-treated cases for 1947 had the shortest period of disability. The difference between the 1947 series and that of 1946 is not statistically significant, but the difference between 1944 and 1947 would occur only 1 in 100 times through chance.

Age.—Cases fell into two main groups, those under 30 and those 30 years and over. As can be seen from Table II, these two groups show a difference of 2.19 days in length of history; this is statistically significant. The difference in the I.H. interval (3.12 days) would occur only 1 in 20 times through chance and the A.D. interval (4.93 days) 1 in 15 times through chance.

Length of History.—Arranging cases into two groups—those with a history of three days or less and those with a history of four to seven days—there is an increase in disability in the latter group of 6.9 days in the A.D. interval, which is statistically significant. Those cases with more than seven days' history gave much longer periods of disability—23 days for the I.H. interval and 30 days for the A.D. interval. It seems clear that the younger age groups have a shorter history and a shorter period of disability, the shorter history being at least one if not the main factor in lessening the time of disability.

Final Movements and Functional Result.—In only one case was there limitation of movement on discharge; this was only 10 degrees limitation of flexion. Some loss of function due to paraesthesia or anaesthesia of the scar and destruction of the pulp in cases of gross sloughing was however, relatively common. Paraesthesia tended to disappear rapidly, especially after compensation.

Incidence of Complications.—No case of arthritis, osteomyelitis, or tenosynovitis arose during penicillin treatment except one possible case mentioned under osteomyelitis

III. Terminal-pulp Infection with Osteomyelitis of the Terminal Phalanx

Diagnosis.—Bony infection may be immediately demonstrable by radiography in late cases, or the diagnosis may be one of suspicion only, confirmed later by radiological evidence. The three factors of Bolton *et al.* (1947)—length of history, amount of tissue necrosis, and previous inadequate incision—are helpful in diagnosis. To these can be added age of patient and the typical bulbous appearance of the terminal phalanx.

Length of History.—In 78 uncomplicated cases with a mean of 4.27 days' history only three gave a history of eight days or more, while of 19 cases of osteomyelitis with a mean of 9.54 days' history only three gave a history under a week and five gave exactly a week's history. Thus a short history does not exclude bony infection, nor does a long history necessitate it.

Age of Patient.—As has been shown in uncomplicated cases, patients under 30 have shorter histories and a shorter disability. In cases of osteomyelitis only two out of 19 (10.5%) were under 30, while 59.5% were under 30 in the uncomplicated cases. In this series only those showing radiological signs of osteomyelitis are included: cases of suspected osteomyelitis never proved radiologically are included under uncomplicated cases.

Surgery.—This was identical with that of uncomplicated aces. Sequestrectomy was never performed until definite radiological evidence was at hand, unless a sequestrum was seen lying free at the primary operation for incision of the pulp.

Cases (see Table II) are divided into two groups: the first 0 cases, (Group 9a) received penicillin for less than 14 days

(mean 8.2 days), the second group of 9 (Group 9b) received it for more than 14 days (mean 20.1 days). This change was due to the realization that a week of systemic penicillin was not controlling cases satisfactorily. Though the numbers are small the difference of 18.5 days in the I.H. interval is statistically significant and the two groups appear to be clinically of similar severity, with a mean history of 10 and 9 days and a mean age of 43 and 40 years respectively.

Progressive Osteitis.—This did not occur after the administration of systemic penicillin except in one case. This case is not included in the figures as it received much of its treatment at another hospital. The extension of the bony infection and involvement of the distal interphalangeal joint occurred a few days after cessation of the initial seven days' systemic penicillin; this should have been avoided if penicillin had been continued for a longer period.

Sequestrum Formation.—In Group 9a one large sequestrum was removed at primary operation and four other cases had small sequestra removed later. In Group 9b no sequestrectomy was necessary, minute pieces of dead bone being extruded in the dressings, while cases in which there was gross radiological disorganization of the terminal phalanx, with separation of the bone into two or more separate pieces, resolved without sequestrum formation, a somewhat deformed phalanx re-forming.

Tenosynovitis.—One probable case was seen in which the middle pulp space was also affected and bilateral incision of the terminal and middle pulp was necessary. Osteomyelitis of the terminal phalanx was present, but there was no radiological evidence of arthritis. Final movement at the terminal interphalangeal joint was only 25 degrees flexion: it is suggested that the diminished

movement was due to some tendon damage with adhesion formation.

Final Result

Movements.—These returned to normal except in the case complicated by arthritis, the case mentioned above as probable tenosynovitis, one with 5 degrees limitation of flexion, and another with 20 degrees limitation. Thus, in general, partial destruction of the phalanx did not limit final movements.

Loss of Soft Tissue and Scarring.—Greater disability resulted from this cause, gross sloughing of soft tissues and multiple incision contributing. Under systemic penicillin treatment the absence of long-continued discharge and its resultant fibrosis and the reduction in the number of sequestrectomies improved the result, but there did not seem to be any regeneration of the soft tissues comparable with the reappearance of the bony phalanx.

IV. Palmar Subcutaneous Infections of the Proximal and Middle Phalanges

Four cases out of 40 subsided without incision. The periods of disability as shown in Table III do not differ significantly from those in uncomplicated terminal-pulp infections.

V. Dorsal Infections of the Fingers

Under this heading are included all dorsal infections except paronychia. Incision was necessary in only six cases, where it was limited to the release of pus under tension when still present after one or two days' treatment with systemic penicillin.

VI. Space Infections (Web, Subaponeurotic, and Thenar)

The numbers seen in each group were small. The results do not show much improvement on non-penicillin-treated cases in previous periods, with the following exceptions: no case suitable for conservative treatment was seen in the subaponeurotic group, but out of 32 web-space infections three resolved without incision, as did four out of six thenar-space infections.

VII. Acute Tenosynovitis

A single daily dose of 200,000 units of penicillin is not sufficient to abort or treat all cases of tenosynovitis (see Case 2); once tenosynovitis was diagnosed the patient was admitted to hospital for more frequent injections of penicillin. Immobilization of the affected finger by a plaster slab was carried out for one week.

Primary Tenosynovitis

Case 1.—This patient had a 24-hours history of a penetrating wound of the fifth finger. Examination revealed tenosynovitis of the fifth finger and ulnar bursitis. As an in-patient he was given systemic penicillin, and a small incision made along the ulnar border of the sheath at the base of the fifth finger released seropurulent fluid. The wound was sutured on the fifth day. Haemolytic streptococcus and *Bact. coli* were obtained from the puncture wound and haemolytic streptococcus from the sheath (*Bact. coli* was penicillin-resistant). The patient defaulted while being followed up as an out-patient, but when last seen he had full movement with the exception of 10 degrees limitation of flexion of the fifth finger and slight loss of gripping power.

Case 2.—Treated as an out-patient with systemic penicillin, 200,000 units daily, for a penetrating wound of the base of the third finger. Signs of tenosynovitis gradually appeared, but were not definite until the fourth day. The patient was admitted for intensive penicillin, and an incision was made to relieve tension in the proximal end of the sheath. Seropurulent fluid showing pus cells but sterile on culture was found. Final result: 5 degrees limitation of full flexion with slight loss of

power. The patient thought there might be slight loss of function, but compensation had not been decided.

Case 3.—Attended as out-patient, with a history of a splinter in the proximal pulp of the third finger. On examination some cellulitis of the proximal pulp was seen; this subsided after two days' treatment with penicillin. The patient defaulted after the second day, to return after one month with acute tenosynovitis of the third sheath. Systemic penicillin therapy as an in-patient and immobilization without incision resulted in cure with full function but 5 degrees limitation of full flexion.

Case 4.—Puncture wound of the base of the third finger with signs of tenosynovitis, resolved with in-patient systemic penicillin therapy. Final result: full function.

Secondary Tenosynovitis

An early case resolved completely, while one late case resulted in sloughing of the distal sheath and adhesions of the tendon to the overlying scar with negligible movement at the distal interphalangeal joint and 10 degrees limitation of flexion at the proximal joint. A third case is mentioned under "Osteomyelitis."

VIII. Acute Arthritis

From three cases seen it was realized that arthritis may occur before or after penicillin treatment without marked physical signs, and that even if arthritis does occur a useful joint should be obtained with only partial loss of movement provided the cartilage has not been too grossly damaged. In one case cartilage destruction must have been considerable, as half of the distal joint surface was sequestered, but limitation of extension was only 10 degrees and flexion 35 degrees.

General Considerations

Systemic penicillin treatment in the out-patient department has resulted in a big saving in bed space. This is shown by the following figures. General surgical admissions to the London Hospital were 11% higher in 1947 than in 1946, while beds available for septic cases rose from 21 to 28. The out-patient clinic for infected hands also expanded by 64%. However, 37 cases of infected hands were admitted during 14 months of systemic penicillin treatment in the out-patient department, as compared with 78 in the previous 14 months, a drop of 52%. Of the 37 cases, four or five were admitted unnecessarily according to present standards. The reduction was mainly due to a fall in uncomplicated but severe soft-tissue infections from 49 cases to 13 and of osteomyelitis from nine to three; and two of these three cases were diabetics admitted for stabilization.

The reduction in pain and tissue-swelling brought about by systemic penicillin improved drainage and allowed many patients to continue work uninterrupted except on the day of incision.

Apart from paronychia, penicillin-sensitive organisms were isolated in all cases except one of osteomyelitis yielding a relatively insensitive *Staph. pyogenes*. Of 94 positive swabs taken from cases of paronychia, 15 grew penicillin-resistant organisms—*Bact. coli* 6, *Proteus* 7; *Ps. pyocyanca*, *H. influenzae*, and a resistant *Staph. pyogenes* one each. These cases took nearly three days longer to heal than the main group, but this is not statistically significant. In seven cases penicillin-resistant organisms alone were isolated. Only three cases showed marked clinical resistance to treatment: two with cultures of *Proteus vulgaris* responded to propamidine cream; one chronic case which had previously received penicillin grew a resistant *Staph. pyogenes* but responded to sulphonamides. Penicillin-resistant organisms did not appear to be secondary invaders, as they were found both in early and in late cases.

Discussion

From an examination of Table IV it will be seen that there is no very startling difference between the non-penicillin- and the penicillin-treated series, but in general the comparison bears out the impression that penicillin shortens the disability, more especially if given systemically, though such a comparison between different papers is not very satisfactory.

Various papers read at the XXIIIrd Medico-Legal Congress in Paris (1946), for cases treated before the general use of penicillin, gave similar periods of disability, such as that of paronychia (13 days' treatment). It was also shown that with advancing age there was increased temporary and permanent incapacity, and that the longer the time before surgical treatment the longer was the period of temporary incapacity; this conclusion applied to infected hands in general and agreed with the results of terminal-pulp infection noted in this paper. However, Bolton *et al.* (1947) found no relation between length of history and disability, but reported increased disability with increased age.

Though the mean period of disability may show only slight diminution with penicillin treatment, it is interesting to see that Curr (1945) and the Medico-Legal Congress report spreading and gangrenous infections. It is in avoidance of these severe infections that systemic penicillin shows the most beneficial results. To prove that such infections are prevented by routine systemic penicillin would need very large numbers of cases. I have, however, seen infection extend along the finger in cases treated by apparently adequate incision but without penicillin, and especially in old and debilitated subjects. These infections have been easily controlled with penicillin in out-patients. The incidence of complications such as osteomyelitis, arthritis, and tenosynovitis is also decreased.

With practice it may be possible to select at first sight all cases that are complicated or appear likely to spread and become complicated, but unless this can be relied upon routine administration of penicillin should be carried out.

Various authors have mentioned conservative treatment, and Webster (1947) concluded that it was impossible to abort a terminal-pulp infection. Experience gained in this series, however, suggests that when the cases are first seen an attempt should be made to decide whether pus is present or not. If present, incision is indicated; if not present, systemic penicillin and local heat may abort or localize the infection. The common practice of applying heat until a finger is "ripe" must be condemned, as once pus has formed delay may result in further destruction of pulp tissues, and if pus has not formed resolution is possible with penicillin. In hospital practice few cases are seen early enough to abort, but in outside practice a larger number of suitable cases should be available.

The method is not advised without full surgical facilities and daily review of cases, for, while pain is often greatly relieved by one or two injections of penicillin, incision may still be necessary.

Summary and Conclusions

Systemic penicillin, 200,000 units in one daily dose, was given as a routine to cases of infected hands in an out-patient department. The results of 380 cases are analysed and compared with those of cases not so treated and with other published results.

This routine did not reduce the period of disability in a marked degree in uncomplicated cases, though there was some definite improvement.

It resulted in the resolution of some early cases without incision and did not increase the disability in cases which had been treated conservatively and which were subsequently incised.

It controlled systemic reaction and spread in severe uncomplicated cases.

It reduced the period of disability and probably the incidence of complicated cases.

It greatly improved the functional end-result in cases of arthritis and tenosynovitis.

It resulted in a considerable saving of in-patient beds, admission of infected hands being reduced by 52% in spite of a much larger out-patient clinic.

It was found in the case of terminal-pulp infection that with increasing age there was a longer history of pain, a longer period of disability, and a greater liability to osteomyelitis.

I wish to acknowledge my indebtedness to Mr. E. C. B. Butler for his encouragement and helpful criticism, to Dr. F. C. O. Valentine for his advice on the bacteriological aspects, and to the authors mentioned for their kind permission to quote their results.

CHRONIC URETHRAL OBSTRUCTION IN CHILDREN

BY

R. J. LAST, M.B., F.R.C.S.

Lecturer in Anatomy and Anatomical Curator, Royal College of Surgeons of England; Formerly O.C. Abyssinian Medical Unit, British Red Cross Society

Chronic obstruction of the urethra is so much more common in the adult than in the child that, except in very specialized urological practice, experience of the latter is usually very limited. The outlook of the general surgeon is thus inevitably coloured by his experience of adult pathology. Where long-continued obstruction exists in the adult, with production of advanced hydronephrosis, relief of the obstruction can usually do little more than arrest the hydronephrosis. In the child, however, reparative powers are so much more active that a very different picture presents itself. A gross hydronephrosis can recover to such an extent that subsequent pyelography will reveal no abnormality whatever. Furthermore, after as much as two years of overflow incontinence the bladder sphincters can regain their tone and preserve continence instantaneously, as was demonstrated in the majority of the 73 cases which form the basis of this article.

All the patients were Abyssinian boys aged from 8 to 16 who had suffered amputation of penis, scrotum, and testes several years previously, the result of intertribal raids and minor warfare. The boys almost invariably showed other evidence of the attacks they had withstood from their aggressors. Depressed scars of the scalp, missing fingers, and deep scars of the forearms were frequent. The mutilation is carried out by grasping the external genitalia, pulling out the mass of tissue, and slashing it through with the angled sword with which many of the Abyssinians are armed. One would expect that the immediate mortality from such injuries would be high, and this impression was confirmed by the accounts of native witnesses. Gross infection of the raw surface occurs, and this accounts for the extreme degree of scarring, which led ultimately to chronic urethral obstruction in the cases under review.

Amputation of penis and scrotum is a rare condition. In most industrial accidents of this nature the skin of the penis and sometimes of the scrotum is avulsed, but the penis itself is usually intact. Owens (1942), in an exhaustive review of the literature, found only 34 cases of denudation, in only 13 of which was the skin of the scrotum also destroyed. Delprat (1944) and Lyons (1945) each reported a case of traumatic avulsion of the penis; in the latter's case the scrotum was also lost. Each claimed that his case was unique in the literature. Rodrigues (1946) reports a case of amputation, but devotes his article almost exclusively to the forensic aspect. Gillies (1948) records three cases of penile loss—two traumatic and one the result of phagedaena—and McIndoe (1948) reports two further cases of traumatic amputation.

First Cases

In June, 1942, at Addis Ababa, two boys, aged 8 and 14, from the Empress Menin School for Orphans were sent by the school medical officer for advice and treatment for urinary incontinence, with the suggestion that there was "something wrong with the bladder sphincter." Each boy presented a similar picture. Mutilation had taken place some seven years previously, and each had been incontinent for about two years. There was complete absence of external genitalia, the former site of which was occupied by a projecting irregular mass of dense scar tissue. From a minute depressed orifice in the scar tissue a small but constant stream of urine trickled down one or other leg. In each case a tense firm bladder reached the umbilicus.

It was apparent that the boys suffered from overflow incontinence resulting from urethral stricture. It was impossible to introduce even the finest lacrimal probe into the opening in the scar tissue. A thread of fine silkworm-gut was used as a probe, and by a combination of rotary and to-and-fro movements it was with difficulty introduced through the stricture into the urethra. On its withdrawal no increased flow of urine resulted. Urine collected in a test-tube placed over the orifice showed no abnormality. "Perabrodil" intravenous pyelography was done. Superimposed circular shadows of three calices, each the size of a walnut on the film, testified to the presence of very advanced bilateral hydronephrosis in both cases. Excretion of the perabrodil was efficient; no other test of renal efficiency could be carried out under the conditions at that time existing in Addis Ababa.

Operation.—In the elder of the two boys the whole mass of scar tissue was removed under spinal analgesia. It was of the consistency of hard rubber, oval in shape, 4 by 2 in. (10 by 5 cm.) in extent, and over 1 in. (2.5 cm.) thick. It was difficult to identify normal urethral mucosa beneath the scar. A silkworm-gut thread introduced through the stricture was of great help in finding the urethra. The bladder emptied spontaneously in the act of transecting the urethra. The stump of penile urethra measured about 1 in. in length. It was split inferiorly, and a mucocutaneous continuous suture of fine catgut was introduced with an atraumatic needle. There was no tension on either skin or urethral mucosa. An indwelling catheter was left in position for four days. The boy was continent after the catheter was removed.

In the younger of the two boys precisely similar conditions obtained. In each case an irregular spiral fistulous track was found coursing through the scar tissue. There was no dilatation of the urethra between the triangular ligament and the scar.

Further Cases

The Empress of Ethiopia supports a school for orphans in Addis Ababa. Many of the boys there were in the same condition. From this source and from local doctors who sent me patients I saw 73 such cases before leaving Abyssinia in December, 1944. The ages of the boys varied from 8 to 16, and in all cases amputation had been done six to seven years before. Incontinence had been present for periods varying between a few months and two years or more. In most of the cases incontinence had begun about five years after the mutilation.

It is impossible to estimate the proportion of cases in which ultimate urinary incontinence results. The 73 cases here summarized were all seen because of overflow incontinence. It is certain that some cases never develop obstruction, for in several adults in whom the condition was seen casually the mutilation had taken place several decades previously and, in spite of complete lack of medical care at the time, there had never been any difficulty in micturition. Reports of such cases are rare in the literature.

The case reported by Lyons, even after plastic repair at the Mayo Clinic, required regular dilatation for some time afterwards, whereas in Delprat's case, in which an indwelling catheter was used and the perineal wound packed, with no plastic repair and considerable infection of the wound, no stricture resulted. In each of these cases the penis and urethra had been avulsed at the triangular ligament. Of the three cases reported by Gillies two apparently had some degree of post-operative obstruction. Certainly in none of my cases did incontinence appear until something like five years after the original mutilation.

In my series there was some variation in the degree of amputation of the external genitalia. That is to say, in some instances remnants of scrotal skin remained, but in only two or three cases was one testis preserved. In almost all the patients the volume of scar tissue was very great, due no doubt to the gross infection which must have followed the amputation. The length of penile urethra which remained was very variable.

In one case, for example, almost 2 in. (5 cm.) of urethra remained, and a dilated sac, ovoid in shape, contained over 1 oz. (28 mg.) of large faceted phosphatic calculi. In this case there was a minimum of scar tissue, and it was a simple matter to slit the dilated urethra and make a mucocutaneous suture 2 in. long. Six months later this large artificial meatus had contracted down to a length of $\frac{1}{2}$ in. (1.25 cm.), but the boy was still continent. In the majority of cases the length of penile urethra varied from $\frac{1}{2}$ to 1 in. and was not at all dilated between the scar and triangular ligament.

It was discovered by accident that the use of a post-operative indwelling catheter was unnecessary and inadvisable. Early in the series one of the boys removed his catheter on the day of the operation; four hours later he was still continent. It had been noticed, as expected, that the indwelling catheter in previous patients had caused some erosion and superficial suppuration of the suture line. Thereafter no indwelling catheter was ever used, and the boys were completely continent immediately after operation. Following micturition, which occurred only four or five times a day, swabbing the suture line and drying it with spirit resulted in rapid aseptic healing. It seemed a surprising thing that after two or more years of gross obstruction and overflow incontinence prolonged enough to cause hydronephrosis the bladder sphincters could regain their function instantaneously. Equally striking was the disappearance of the hydronephrosis, to be referred to later. In no case was there urinary infection.

Late Results

The immediate results were good in all cases operated on, complete continence being established at once. The later results were less satisfactory. In several of the earlier cases great contraction of the artificial meatus occurred, and dribbling of urine reappeared after about six months. Second operations, with a more generous slitting of the urethra posteriorly and a resultant longer line of mucocutaneous suture, were performed in these cases, and it became abundantly apparent that in all cases slitting of the remnant of penile urethra as far back as possible was very necessary in order to secure the longest possible line of mucocutaneous suture. Of equal importance was the minimizing of post-operative fibrous-tissue formation by the meticulous removal of all scar tissue at the operation and the securing of primary union by the avoidance of post-operative indwelling catheters and keeping the wound dry.

After these procedures were adopted late results appeared to be uniformly good. The period of follow-up was too short

many of the cases, however, and it is quite possible that the ultimate results are less satisfactory. Contraction of the artificial meatus certainly seemed to be a continuous process in all cases, but fortunately in most of the boys it appeared to have ceased before the orifice became pin-point and obstruction recurred. But as it required five years for obstruction to occur after the original mutilation perhaps at least this period should elapse before a plastic repair is pronounced successful.

In only one case has complete failure to be recorded. Here the stump of penile urethra projecting beyond the triangular ligament was very short. Slitting of the urethra was out of the question, and mucocutaneous suture transversely around the short stump of urethra was all that was possible. Continence was maintained for only six months, and thereafter weekly dilatation of this post-operative stricture was necessary to preserve continence. Several plastic procedures were considered in this case, but none was ever tried out.

Should an attempt have been made to lay open the membranous urethra, with a long suture line to a skin tube previously constructed for the purpose? Apart from the almost certain risk of damage to the external sphincter I felt that the chances of resultant stricture were very high, and should such a stricture have occurred its regular dilatation would have been more difficult and probably more painful than dilatation of the existing stricture at the triangular ligament. At that time I was not aware of the plastic repairs that were being performed by Gillies, McIndoe, and others, but in retrospect I still feel, in view of the contraction at the artificial meatus in all cases, that in my hands post-operative stricture would have occurred at the junction of urethral mucosa and skin tube.

Other Factors

Cosmetic Repair.—It was felt that the construction of an artificial penis was not called for in those patients (all except two or three) who had lost their testes, and efforts were directed exclusively to the cure of urethral obstruction by the production of an artificial meatus which would remain patent.

A problem which caused great anxiety was the question of what to do in the two or three cases in which one testis remained. In these cases, in which there was no penis at all and therefore no apparent means of sexual gratification, and having regard to the lack of inhibitions which normally characterized the life of these people, it was felt that castration would be a kindly act. Nevertheless, it was not done. In retrospect I thought that was a mistake until I read the articles by Gillies and McIndoe, and I am now glad that I allowed these boys to retain their solitary testes. A surgeon in Addis Ababa may at some future date be able to perform such operations as those authors describe and restore sexual function to these unfortunate individuals.

Recent Mutilation.—I saw only one case of recent mutilation, and that prior to the series of late cases reviewed here. In 1941, during intertribal fighting in Abyssinia, a boy aged about 3 years was brought to me. The whole of his external genitalia, including both testes, had been amputated a few hours before. Bleeding had been comparatively slight, the wound was a clean incised one, and skin retraction had left a raw area about 2 in. in diameter. In the centre of the wound the stumps of the three corpora presented. I was working in the field at the time and sent him back to hospital, but the parents refused treatment and took him away.

Recovery of Hydronephrosis.—Apart from the recent case referred to above, all the boys had dilated bladders with overflow incontinence, which had been present for periods of up to three years. In every case in which pre-operative intravenous pyelography was done (some fifteen or sixteen in all) hydronephrosis was evident. The dilated kidneys were palpable in the majority of the boys. These cases were seen during the war years, when supplies were

short and great economy in the use of parabrodil was necessary. Attempts to procure a child's cystoscope for post-operative retrograde pyelography failed. Consequently I can report only three post-operative intravenous pyelograms. In each of these three patients, whose pre-operative pyelograms had shown advanced hydronephrosis, the shadows of a slender pelvis and concave calices had replaced the three circular shadows of the original pyelograms. In no case was the kidney palpably enlarged after operation, and I had the impression that the three cures demonstrated by pyelography were typical of the other cases also.

Summary

After amputation of the external genitalia in boys, untreated at the time and always grossly infected, overflow incontinence due to cicatricial contraction does not appear earlier than about five years; in an uncertain proportion of cases it does not occur at all.

Overflow incontinence, present for as long as two years or more, is relieved immediately the obstruction is removed. The bladder sphincters regain their function instantaneously.

An artificial meatus continues to contract for many months (perhaps for several years) after operation. Indwelling catheters across the suture line are to be avoided at all costs.

In the absence of urinary infection gross hydronephrosis due to low obstruction is curable in children.

NEPHROCALCINOSIS INFANTUM WITH HYPERCHLORAEMIC ACIDOSIS

By

H. J. BOUTOURLINE-YOUNG, M.D., M.R.C.P.
D.C.H.

Paediatric Registrar, St Mark's Hospital, London, W2

At the International Paediatric Conference held in London in 1933 Lightwood demonstrated post-mortem specimens from infants showing calcification within the renal collecting tubules. There was no abnormal extrarenal calcification or any sign of endocrine disease. In 1935 he described the clinical picture: failure to thrive, anorexia, vomiting, constipation, and pronounced hypotonia. A trace of albumin and a few leucocytes or epithelial cells were usually found in the urine. The previous suggestion of Putschar (1929) and of Thatcher (1931) that hypervitaminosis D might be the explanation of such a clinical picture with renal calcification was rejected. In a female infant with these clinical features Lightwood, MacLagan, and Williams (1936) demonstrated an acidosis which persisted for weeks.

Lightwood (1946) recorded a further case in an infant. The clinical features were similar to those he had previously described, and at necropsy the kidneys showed deposits of calcium both within and external to the renal collecting tubules.

Butler, Wilson, and Farber (1936) described persistent dehydration, hyperpnoea, hyperchloraemia, and diminished alkali reserve in four cases. Large deposits of calcium were observed post mortem both within and adjacent to some of the renal collecting tubules. Their patients were dehydrated in spite of a satisfactory fluid intake, and

OCCUPATIONAL MEDICINE

Occupational Medicine and Industrial Hygiene. By Rutherford T. Johnstone, A.B., M.D. (Pp. 604; 117 illustrations, 7 in colour. £2 10s.) London: Henry Kimpton. 1948.

Many aspects of occupational medicine are considered in this book. It includes historical and medico-legal data as well as descriptions of clinical syndromes and special industrial processes. The author stresses the need for wider recognition of the importance of industrial medicine both among leaders of industry and members of the medical profession, and presents a scheme for teaching undergraduate and postgraduate students. He emphasizes the importance of occupational hygiene in the field of preventive medicine.

The book begins with a brief history of the development of occupational medicine as a special study. The author praises the early work of Ramazzini and his interest in the health of the worker, and pays tribute to all who have carried this work to its present stage. He then expounds clearly his views on the aims and scope of industrial medicine in the future. Chapters on pre-employment examination, job placement, and job analysis indicate how some of these aims may be achieved. Discussion on the problems of workmen's compensation and the medico-legal complexities are of limited interest to readers outside the U.S.A.

The next section of the book is mainly about the hydrocarbons and the toxic gases. He discusses the chemistry and gives details of the use of particular compounds in industry. The symptoms and signs of intoxication are perhaps less clearly described than the nature of the hazard and methods of its control, but throughout the book complete case records are reproduced when possible to illustrate the main features. A discussion on thioglycollic acid and the thioglycollates, and also on some of the latest "weedicides," illustrates the author's awareness of the daily appearance of new substances which may prove toxic and his wish to make all physicians similarly aware of new risks.

Johnstone gives a full account of the toxic hazards arising from metals in industry. In the chapter on beryllium he draws attention to an important new problem, and in the chapter on lead poisoning he presents the varying views on the storage of lead and its excretion. He quotes at length from several authorities and gives many references both on this aspect and on that of diagnosis. He personally has abandoned treatment of lead poisoning by the method of attempting to store lead in the bones during the acute stage of intoxication, with subsequent controlled "deleading," and prefers to concentrate solely on the incidental effects of lead. He describes his own method of treatment, and also gives a detailed account of the alternative programme. Clearly this controversy is not yet settled.

The final section is on the dusts. Many readers will disagree with some of the author's opinions. I wonder whether our knowledge of the effects of carbon dust is sufficient for him to say that "miners reveal a greater fibrosis than that of the non-exposed, but it is a non-disabling fibrosis unless the carbonaceous substance is combined with siliceous material." The type of pneumoconiosis found in South Wales coal-miners suggests that this is not so. There is an unbiased discussion on the value of aluminium dust therapy in silicosis, and useful chapters on tuberculosis in industry and on the inert dusts. Descriptions of special industrial processes are clear and particularly well illustrated. He outlines the principles of x-ray diffraction and dust-counting methods and describes in detail the method of administering oxygen under pressure.

Such statements as, "It is advisable to consult chest x-rays for they may reveal pathology of varying degrees," which occurs when discussing "laboratory findings" in persons exposed to dangerous amounts of gasoline, lack clarity. The reader detects at times a sense of indecision when Johnstone quotes at length from publications on a particular subject without indicating which idea he believes to be right. But these are minor criticisms of a book which contains much useful knowledge.

DONALD HUNTER.

RECENT CARDIOLOGY

Recent Advances in Cardiology. By Terence East, M.A., D.V., F.R.C.P., and Curtis Bain, M.C., D.M., F.R.C.P. Fourth edition. (Pp. 454; 27 plates and 98 text-figures. £1 6s.) London: J. and A. Churchill. 1948.

Nearly twenty years have elapsed since the first publication of *Recent Advances in Cardiology* by Drs. East and Bain. Comparison with the present edition shows how remarkable has been the transformation of cardiological knowledge in the two decades. Such rapid advances entail a risk that students will concern themselves with spectacular new developments when they are still unsure of fundamental principles. The authors must, of course, discuss new subjects, as the title of their book implies, but, building as they do on the earlier editions, they strike an admirable balance.

Those seeking an exposition of familiar problems such as cardiac dyspnoea or the arrhythmias will find them clearly presented, even though the style is staccato in places. More advanced students will find references to such subjects as the newer theories of the electrocardiogram, ventricular gradient, cardiac catheterization, and angiocardiology. So faithfully have the authors expounded these developments that they have had not only to add to the volume but to rearrange it completely. The revised chapter on congenital heart disease is perhaps less well balanced than others. The bibliographies deserve special mention, for they have become extensive and informative contributions showing the evolution of each branch of the subject. I recommend this work without reservation to all students of cardiology; the beginner and the more advanced student alike will find his needs met and his interest stimulated.

K. SHIRLEY SMITH

IRRESPIRABLE ATMOSPHERES

Breathing in Irrespirable Atmospheres, and, in Some Cases, also Under Water. By Sir Robert H. Davis, F.R.S.A. With foreword by Sir Leonard Hill, F.R.S., LL.D., M.B. (Pp. 386; fully illustrated. 25s.) London: The Saint Catherine Press.

This new book is intended primarily for lay readers, particularly for those who use the many types of breathing apparatus described. The author describes fully the problems of altitude flying, war and industrial gas poisoning, fire fighting, mine rescue, and resuscitation. In most sections he discusses severally the evolution of each problem and the development of the various types of apparatus to cope with it. The resultant mixture of history, physiology, technical problems, and description of apparatus is in the tradition of Sir Robert's previous book, *Deep Diving and Submarine Operations*, and, although not pleasing to a purist, will hold the interest of the reader. The physiology is simplified and therefore dogmatic.

This book is a remarkable record of achievement in many fields and contains much that is of interest to the specialist. There is no doubt that it will join its companion on the shelves of all those interested in respiratory problems.

K. W. DONALD.

THE RORSCHACH TEST

Principles and Practice of the Rorschach Personality Test. By W. Mons. (Pp. 164. 12s. 6d.) London: Faber and Faber.

Though the Rorschach test has become firmly established and is widely used in Britain, no really elementary textbook has been published until now, and the test remains largely in the hands of the expert. One unfortunate result of this is that its potentialities are not always realized as fully as they might be. The tester is seldom a clinician and so does not select his subjects, and the clinician does not know how to select those patients for whom the test can most appropriately be used. Both classes of reader will welcome this book. Dr. Mons gives an account of the theoretical basis and of the actual technique of the test, and provides the clinician with information about the indications for its use and about its limitations. He emphasizes the fact that this is an introduction only; he is writing for beginners, and does not take for granted in his readers any previous acquaintance with the test. He has

evolved his own technique of interpretation, and this he describes minutely and clearly. The reader will have little difficulty in following the instructions, and will find that most of his difficulties and questions have been answered. Although for so small a book it is remarkably comprehensive, it is by no means an exhaustive description of all the theories and techniques which have grown up round the Rorschach test, especially in recent years. It is rather an account of the views and practice of one exponent, evolved by him from an extensive acquaintance with the literature and wide personal experience. It is to be recommended as a most readable introduction to the subject.

ELIOT SLATER.

SHAKESPEARE'S SON-IN-LAW

The Shakespeare Circle. A Life of Dr. John Hall, Shakespeare's son-in-law, with glimpses of their intimate friends and relations. By C. Martin Mitchell. (Pp. 116; illustrated. 12s. 6d.) Birmingham: Cornish Brothers, Limited.

John Hall was born in Bedfordshire in 1575. He matriculated from Queens' College, Cambridge, at the age of fourteen, and is entered in the records as M.A. in 1597. He studied in France, but he did not take a medical degree and was generally known as Master John Hall. It is suggested that an ecclesiastical licence gave him his qualification and he settled in Stratford-on-Avon to practise medicine about the year 1600. He married Susanna, Shakespeare's daughter, in 1607, the year of the production of *The Life and Death of King Lear* and his *Three Daughters*, and in 1610 they moved into New Place to live with the poet. Susanna died in 1649, fourteen years after her husband. Her epitaph, its quality sufficient to prove that her father died before her, is well known:

"Witty above her sexe, but that's not all,
Wise to salvation was good Mistress Hall.
Something of Shakespeare was in that, but this
Wholly of him with whom she's now in blisse. . ."

John Hall became a very successful physician whose practice extended beyond Warwickshire. He refused a knighthood (does this make him unique among physicians?), preferring to pay £10 for his affront to that fount of commercial honour. James I. John Hall was a great man in Stratford and both in 1617 and in 1622 he refused nomination to the Town Council "because his work prevented his attendance." His ultimate acceptance of nomination in 1632 appears to have been a tactical move in his violent quarrel with the Corporation, for he was soon expelled for "sundry other misdemeanours and continual disorders." It is charitable, as his biographer suggests, to regard his acrimonious behaviour in these controversies as evidence of ill-health. He died suddenly in 1635, and in 1657 his friend and admirer, Dr. John Cook, of Warwick, published 200 of his case notes with the title *Select Observations on English Bodies or Cures both Emperically and Historically performed upon very eminent Persons in desperate Diseases*. . .

Mr. Martin Mitchell's book contains all (and more) that is known of John Hall and gives in addition much information about other relations and friends of William Shakespeare.

D. V. HUBBLE.

One has only to read the introduction to *Physical Treatment of Injuries of the Brain and Allied Nerve Disorders*, by Miss K. M. Hern, M.C.S.P. (Baillière, Tindall and Cox; 10s. 6d.) to see that the author is an enthusiast. The theme of physical treatment she advocates is active work—"activity with interest, variety, and achievement." She emphasizes the essential importance of rhythm, for the patient must do much more than slow deliberate concentrated movement with an affected limb; he must be able to exhibit co-ordination and rhythm. She describes the techniques of active re-education in detail, and they are well illustrated. She emphasizes the value of ball games, recommending three different sizes of ball and giving clear details of their use. In the chapter on apparatus she rightly points out that, though it is useful, its absence should be no deterrent to the physiotherapist, who should be able to adapt and improvise. She makes many suggestions for such improvisations. This book is thoroughly practical. The author does not lose sight of the little important things in life, and she reminds us that the spastic patient should be able to handle his own money and do up his own buttons. All who are interested in rehabilitation will study the book with profit.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Manual for Medical Records Librarians. By E. K. Huffman, R.R.L. 2nd ed. revised. (Pp. 371. \$4.50.) Chicago: Physicians' Record. 1948.

The author describes library organization, methods such as micro-filming and card-indexing, and includes a glossary of medical terms.

The Trial of Gogawa Sadaichi. Edited by C. Sleeman, B.A. (Pp. 245. 18s.) London: William Hodge. 1948.

Describes the trial of a group of Japanese war criminals.

Thomson-Walker's Genito-Urinary Surgery. Edited and revised by Kenneth Walker, M.A., M.B., B.Ch., F.R.C.S., T.I.C.S. 3rd ed. (Pp. 956. 60s.) London: Cassell. 1948.

Out-of-date material has been eliminated, and new work on the sulphonamides, antibiotics, and mandelic acid described.

Bacteriology. By F. W. Tanner and F. W. Tanner, Jr. 4th ed. (Pp. 625. 27s.) London: Chapman and Hall. 1948.

An introductory textbook for the student.

Comparative Physiology. By B. T. Scheer, Ph.D. (Pp. 563. 36s.) London: Chapman and Hall. 1948.

A textbook for the advanced student grounded in zoology.

Recent Advances in Respiratory Tuberculosis. By F. Heaf, M.A., M.D., F.R.C.P., and N. L. Rusby, M.A., D.M., F.R.C.P. 4th ed. (Pp. 290. 21s.) London: J. and A. Churchill. 1948.

Besides bringing the book up to date the authors have included new chapters on the patient's environment and social circumstances.

Clinical Endocrinology. By L. Marin, M.D., F.R.C.P., and M. Hynes, M.D., M.R.C.P. (Pp. 222. 15s.) London: J. and A. Churchill. 1948.

A short textbook intended particularly for general practitioners and postgraduate students.

The Development of Modern Medicine. By R. H. Shryock. (Pp. 384. 21s.) London: Victor Gollancz. 1948.

The development of medicine is related to the intellectual background and social history of the times. First appeared in the U.S.A. in 1936.

Documenta Ophthalmologica. Edited by F. P. Fischer, A. J. Scheffer, and Arnold Sorsby. Vol. 2 (Pp. 461. No price.) The Hague: W. Junk. 1948.

Includes papers by various authors on the electroretinogram, siderosis retinae, and experimental trachoma.

Dietetics. By A. Nimalasuriya, M.B., B.S., M.R.C.P. (Pp. 138. No price.) Colombo: The Times of Ceylon. 1948.

Intended for the school-teacher and intelligent parent.

Physiology of the Eye. By H. Davson, D.Sc. (Pp. 451. 32s.) London: J. and A. Churchill. 1949.

A textbook for the general medical student and prospective specialist in ophthalmology.

Science in Films. Edited by B. Lloyd, M.Sc., Ph.D. (Pp. 238. 15s.) London: Sampson Low, Marston. 1948.

Includes an article on the use of films in medicine and very extensive references.

Lumbalgien. By H. Debrunner. 2nd ed. (Pp. 121. 12.50 Swiss francs.) Berne: Huber. 1948.

A clinical account for the general practitioner

Psychiatry in General Practice. By M. W. Thorne, M.D., D.Sc. (Pp. 659. 40s.) London: W. B. Saunders. 1948.

A practical account of diagnosis and treatment, with case histories.

Treatise on Surgical Infections. By F. L. Meleney, M.D. (Pp. 713. 63s.) London: Geoffrey Cumberlege. 1948.

The author discusses sterilization and asepsis, the infection of surgical wounds, the body's defences, and treatment.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 29 1949

CAUSE FOR DISSATISFACTION

That there is widespread dissatisfaction among the profession with the conditions of service under N.H.S. is plain from the correspondence in the *Journal*, resolutions passed by Divisions, and discussions in committees. The two chief points of grievance are overwork and under-pay—points that were stressed in the House of Commons on Jan. 21 when Sir Henry Morris-Jones opened a debate on the adjournment. "There is no doubt," he said, "that large numbers of medical men are extremely unhappy and very perturbed about their present position and the working of the Act." He considered that in the large industrial areas medical men had on the whole gained financially, but that the incomes of practitioners in residential, rural, and seaside resorts had fallen. He also drew attention to the fact that many specialists had suffered drastic reduction in income. He thought that the Act would survive the present troubles, but that the basis of remuneration should be reconsidered. Mr. Fred Messer, who is Chairman of the Central Health Services Council, said that as one who had day-to-day experience of the administration of the Service he had found complete co-operation from every section of the medical profession. He confirmed what Sir Henry said about the great hardship "being experienced by many general practitioners at present," adding later "clearly, everybody knows that the situation cannot remain as it is."

Mr. Messer considered that six months' experience was sufficient to show what major changes should be made in the Service. Overwork and under-payment were stressed by Mr. Ralph Assheton, who asked whether doctors might not be given more help in dealing with work that was strictly non-medical, such as filling in forms and certificates. Mr. John Edwards, Parliamentary Secretary to the Ministry of Health, said that about 40,000,000 people had placed their names on the lists of general practitioners and that out of about 21,000 practitioners 18,165 had entered the scheme. Out of 10,000 dentists in general practice 8,988 had come into the Service and had treated 2,200,000 patients, 1,200,000 being under treatment at present; more than 2,500,000 people had had their sight tested, and over 3,000,000 pairs of glasses had been supplied or were on order. These figures, he observed, gave some idea "of the magnitude of the whole operation," which had been completely underestimated. Mr. Edwards said that when everything had been taken into account the payments to general practitioners in the scheme from the appointed day to March 31 of this year would amount to £32,500,000; in addition, superannuation contributions from the Exchequer would amount to £1,600,000 extra. He believed that the overall sum available would secure that doctors were paid in accordance with the Spens recommendations. He agreed that some sections of the medical profession were now very much overworked:

I say to the House quite seriously that when the final payments for the period July 5 last to March 31, 1949, have been made we shall then be able to see whether the remuneration of general practitioners does, in fact, accord with the Spens recommendations. If it does not the arrangements will be reviewed to see what adjustments are necessary to give effect to those recommendations.

Mr. Edwards said it was impossible to agree that the private patient should be permitted to obtain drugs through the Service, and at the same time he said he did not know how, except through new administrative technique, they could separate the Briton from overseas from the foreign visitor. We are therefore faced with the curious anomaly that the British patient who wants to go privately to a doctor cannot obtain medicines and appliances through a Service which he finances as a taxpayer, while the foreign visitor, paying nothing towards the Service, can get all his benefits free of charge. This is an absurd position, especially when we recall that one of the reasons Mr. Bevan gave the Negotiating Committee in December, 1947, for reserving beds in State hospitals where patients could be treated with no ceiling on fees was that these might be occupied by wealthy foreign visitors wanting to take advantage of medical and surgical skill in this country.

A Special Representative Meeting, following a special meeting of the "Panel Conference," has been called for March 29, when no doubt the dissatisfaction with the present terms and conditions of service will be freely discussed. It is good to know that such prominent spokesmen as Mr. Messer have admitted in the House of Commons that there are grounds for this dissatisfaction and that matters cannot rest as they are. Many medical men who have written to the *Journal* have severely criticized the British Medical Association, holding it responsible for much that has been amiss. But, as Dr. Dain said at a meeting of the General Medical Services Committee the other week, the Association must proceed one step at a time on the basis of evidence. The first-fruits of this procedure were the increase of the Mileage Fund from £1,300,000 to £2,000,000—a figure representing, as Mr. Edwards pointed out in the House of Commons, three times the amount available under National Health Insurance. Many critics would seem to leave out of consideration the history of the negotiations that went on between the B.M.A. and the Ministry from the time of the Beveridge Report in 1942 to May, 1948. As Dr. R. W. Cockshut points out in a cogently written article in this week's *Supplement*, the B.M.A. never lost an opportunity of declaring its whole-hearted support for a comprehensive Service and the Representative Body made no attempt to alter its policy in favour of 100% service. That this policy represented the general wish may perhaps have been confirmed by the fact that fewer than 6,000 medical men and women contributed to the Fighting Fund opened by the B.M.A. early last year after the plebiscite of January, 1948. Mr. Messer has testified to the co-operation offered by the profession in the working of the new Service, which makes it all the more imperative that the present wrongs and injustices shall be remedied at the earliest possible moment. But a blunderbuss prescription will not serve the purpose of the profession. The collection of evidence is proceeding, and on the basis of this remedies will be sought and secured.

PENICILLIN AND THE INFECTED HAND

For some years before the introduction of the sulphonamides and penicillin the surgical treatment of the infected hand had been guided and dominated by the outstanding researches of Kanavel. The sulphonamides brought no striking improvement in results, and there were at first too sanguine hopes that surgical incision could be avoided or at any rate limited in extent, but with the advent of penicillin there was a fresh wave of enthusiasm and renewed interest in this important problem. During the last decade or more it has been gratifying to observe how an increasing sense of responsibility has guided surgeons in their treatment of infected hands. It was gradually appreciated that Kanavel's teaching could not bear fruit with the haphazard organization of the average hospital, nor could junior and inexperienced resident staff, however enthusiastic, be expected to produce more than mediocre results without expert supervision. The setting-up of special clinics for the treatment of infected hands was the natural outcome of this experience, and it is fortunate that the advent of the antibiotics should have coincided with improved organization in hospitals.

In assessing the merits of any new method of treatment the clinician must pay careful attention to the many factors which may influence his interpretation of the results. In the last few years a number of important papers have appeared on the subject of penicillin treatment of the infected hand, and results have improved remarkably, especially in the more serious cases. In acute suppurative tenosynovitis Florey and Williams¹ reported favourably on local penicillin treatment combined with the classical type of surgical incision. At a later date several workers found that the best results were obtained by minimal surgery and adequate systemic penicillin treatment.^{2,3} Frequent injections of penicillin in effective doses have permitted a limited form of surgery tantamount to simple decompression of the synovial sheath, and this has resulted in rapid healing and has accelerated functional recovery.

In less severe infections it has been more difficult to demonstrate the advantages of penicillin treatment, though most surgeons have been impressed by some of the results. Elsewhere in this issue Mr. G. A. Barclay reports a series of 357 cases treated at the infected hands clinic of the London Hospital; few would disagree with his conclusion that penicillin has improved the results of treatment in cases of complicated felon, and he makes but modest claims for the drug in the less severe cases. The results obtained are attributed to the use of systemic penicillin, but it would seem that Mr. Barclay has used local dressings of penicillin cream as a routine in all cases where there was no necrotic tissue. Many would question the value of a single daily intramuscular injection of 200,000 units of aqueous penicillin solution, though this somewhat empirical method appears

to be quite widely used in this country. Florey and Williams used with success local penicillin treatment alone in both mild and severe infections, and it seems possible that in Mr. Barclay's series the local penicillin cream may have been as efficacious as the systemic injections.

It is difficult to adjudicate on this subject, and, while it would be unjust to say that a single daily intramuscular injection of penicillin is of little value, it should be remembered that there is as yet no published work which demonstrates the relative merits of this technique and more orthodox methods of penicillin treatment. Bolton, Catchpole, and Jepson⁴ have reported a series of cases of pulp infections treated with penicillin powder locally and twice-daily intramuscular injections of 100,000 units. They noted no significant improvement in the uncomplicated cases, although, like Barclay, they thought this method valuable in cases complicated by bone infection provided treatment was continued for two weeks or more. Webster⁵ was not impressed by the results obtained in cases treated by the local application of penicillin combined with injections given by the "one-shot" method, and when the drug was administered in a delaying medium of beeswax and oil he did not find that bacteriostatic concentrations were maintained in the blood even when 250,000 units was given. The much more satisfactory blood concentrations attained by using procaine penicillin have recently been reported in the *Journal* by Jones and Shooter,⁶ who confirmed the original work of Herrell and his colleagues.⁷ It would be of great interest to study a series of cases of infections of the hand treated by this preparation, both alone and combined with local penicillin therapy. The doubtfully adequate systemic methods used to date have not produced uniformly convincing results, particularly in the case of simple felons, although they may have been of value in modifying or aborting cellulitis and in aiding the control of infections which involved the bone.

Preoccupation with the problems of penicillin treatment should not cause neglect of further fundamental principles in the treatment of hand infections. Pilcher and his colleagues⁸ have recently stressed the importance of immobilization, and while systemic penicillin treatment may permit some relaxation of this measure its value should not be forgotten. Pilcher has also emphasized the dangers of too early incision and has advocated delay until pus has certainly localized; this advice has not found wide support in the case of pulp infections but should at least be accepted as a reasonable warning against indiscriminate and untimely incision. The use of heat locally has tended to fall from fashion. Hand baths are positively harmful, but dry heat applied in the form of short-wave diathermy may be of some value. However, the benefits of the latter are sometimes fully offset by the disturbance of dressings and interruption of immobilization, while the physiotherapy department is probably better employed in restoring function to those patients who have had more severe infections with delayed healing.

In conclusion, it may be wise to repeat that certain aspects of systemic penicillin therapy still require illumination. This is not to deny the undoubted value of penicillin wisely and properly used, but the present need is for further

careful study of groups of cases treated with penicillin, particularly with the latest preparations, and it may well be that we shall then look askance at some of the methods of systemic therapy which are at present in vogue.

NEW RHEUMATISM CENTRES

The South Western Regional Hospital Board has approved a scheme for the treatment of rheumatic diseases drawn up by its Rheumatism Subcommittee. A main treatment and research centre of 400 beds, 200 being for research purposes, will be set up at Bath; there will be treatment centres of 20-40 beds at various places including Gloucester or Cheltenham and Taunton, and diagnostic centres with 10 beds at Bristol, Yeovil, and other places. Peripheral clinics will be established at a number of the country towns in the area. A director of the service is expected to be appointed shortly.

The Leeds Regional Hospital Board has submitted to the Minister of Health a similar scheme for a diagnostic, treatment, and research centre at Harrogate. It involves the purchase of three hotels, the extension and improvement of the Royal Bath Hospital, and the setting up of a school of physiotherapy. The development will cover five years. The first stage in the programme will be the reconditioning of the Royal Bath Hospital. The total number of beds to be provided is 900, where about 8,000 patients a year may be accommodated. The patients will be selected at clinics which already exist or are being developed in nine Yorkshire towns, and additional clinics are likely to be established in five others. The Royal Baths themselves, which are owned by the corporation and where 1,000 ambulant cases a day can be treated, will not be taken over. One of the three hotels, the Harlow Manor, will be equipped with laboratories and research facilities. It will be an annex to the Royal Bath Hospital and will have accommodation for 100 patients and staff. The school of physiotherapy will be developed in co-operation with Leeds University and the board of governors of the teaching hospital, and may be either a separate entity at Harrogate or part of the existing school at Leeds General Infirmary. The scheme is described in a brochure which was presented to Mr. Bevan when he visited Leeds on Dec. 8. Its importance is not enhanced by the lavishness with which it is set out. While paper is so difficult to obtain it seems an extravagance for anybody—even a regional hospital board—to present its ideas on 32 large art pages of which many are only half-filled and two entirely blank.

AETIOLOGY OF ERYTHEMA NODOSUM

The aetiology of erythema nodosum is still a matter of considerable debate, and a debate in which the various proponents urge their views with much vehemence and often with little regard for alternative theories. From the discussions, however, there are emerging certain fairly definite views. Perhaps the most important of these is that there is no single cause for erythema nodosum, but that it may result under the right conditions from a variety of infections. In different countries and at different age periods different infections are most common. In children in Scandinavia¹ it seems to be rare for erythema nodosum to occur except in association with a primary tuberculous infection. In this country, while primary tuberculosis is the precipitating factor in about 70% of children, it is relatively uncommon as a cause in adults, in whom infection

with a haemolytic streptococcus more often appears to be responsible.² In the San Joaquin Valley of California on the other hand, the "bumps," as it is known locally, nearly always results from infection with the *Coccidioides immitis*.

Favour and Sosman³ have recently reported their findings in 155 cases of erythema nodosum in Boston; 102 of the patients were adults. They found a marked seasonal incidence in January, and they confirm the well-known fact that in children the sexes are nearly equally affected (60% of the cases being girls), while the majority of adults affected are women (86%). In this series tuberculosis was uncommon as an antecedent infection, but 80% of the patients had an associated respiratory infection in the immediate past, and from half the patients whose throats were swabbed haemolytic streptococci were recovered. In 10 of 61 patients who had chest radiographs taken enlargement of the hilar shadow was found on one or both sides, but the authors were not prepared to regard this as evidence of tuberculosis in the absence of any signs of subsequent calcification. This, however, is probably not sound, since it is clear that not all cases of tuberculous adenitis heal by calcification. Neither did they accept the view that the radiological changes in the lungs in some cases might be due to sarcoidosis. Nevertheless, rare though erythema nodosum may be in this interesting disease, there is no doubt that it does sometimes occur.

In the majority of the adults, but in only one-third of the children, migratory polyarthritis was part of the clinical picture, and in some of the adults similar attacks of polyarthritis without erythema nodosum had occurred up to twenty years before. The belief that erythema nodosum is a manifestation of acute rheumatism dies hard in this country, yet despite the frequency of fleeting joint and limb pains Favour and Sosman could find no evidence that there is any close relationship between the two diseases. In fact they conclude quite categorically that erythema nodosum is not a form of rheumatic fever. At the present time acute rheumatism, acute nephritis, erythema nodosum, and Henoch-Schönlein purpura are all associated with the "post-streptococcal state." Favour and Sosman's paper stresses once again the great importance in the causation of many diseases of individual predisposition and constitution—the diathesis of our forebears—as compared with the infecting or precipitating factor.

TOWN PLANNING AND HEALTH

The planning of new towns and of developments of old towns is now going ahead in various parts of the country. The lay-out of new towns was discussed at the recent Public Health and Works Congress at Olympia, but little was said about health in relation to the planning; it seemed to be considered sufficient that a health centre should be provided and certain residences on housing estates allocated to doctors, nurses, and other health workers. At a discussion organized recently by the Planning Forum in London the subject of health and planning received more thorough consideration. Dr. R. S. E. Schilling pointed out the importance of the relation of industrial to residential areas. In large cities the long distances which people have to travel to and from their work are often the cause of more fatigue than the work itself and expose the worker to the risk of infection and of accident. If smoke, fumes, and noise could be reduced there is no reason why industrial and residential areas should not be brought more closely together and the distances travelled by the worker considerably shortened. More care should be taken to ensure that suitable work is available for that section of every

community which is in some degree handicapped by age or disability and yet is capable of useful effort.

Housewives, the largest occupational group in the country and the least regarded, should be given conditions in which they can do their work without strain. Day nurseries and nursery schools are helpful, but better planning in the home and in the relation of the home to the neighbourhood is required. The floor space in the new houses which are now being built by local authorities is an improvement on pre-war standards, but houses still more spacious are needed for the comfort and happiness of parents and children. More space, of course, calls for improved heating, but this is a reform well overdue in house-building in this country. In a recent letter to *The Times* the chairman of the National Corporation for the Care of Old People mentioned that the planning of new towns offered an opportunity for the building of houses, flatlets, and residential clubs specially designed for old people. It is encouraging that the chairman of the Crawley Development Corporation in a subsequent letter in the same newspaper emphasized that those who plan new towns must undertake research into the social problems of old age if they intend to do their job properly.

It ought not to be too much to expect that the industries to be located in new towns should be as varied as local conditions will permit and that an optimum size for a factory be laid down. As Dr. Schilling pointed out, it is not enough to eliminate dirt, ugliness, and squalor from an industrial environment: human feelings must be considered. The very large factory employing many hundreds of people can be a lonely, barrack-like place. In the view of the Planning Forum a community of, say, 40,000 to 50,000, with an industrial population of 16,000, ought to have full responsibility for its own industrial health service, which should be closely integrated with the public health services. Specialists at regional level should be available for consultations and to see that adequate standards are maintained. Moreover, an industrial health service should be started as soon as large-scale building begins, in order that it may provide in the first instance for the health and safety of the builders themselves.

CIRRHOSIS AND COLITIS

The relationship between nutritional deficiency and certain forms of hepatic disease is now well established both in experimental animals and in man. It is therefore to be expected that cases of hepatic insufficiency might be found with unusual frequency in association with conditions such as ulcerative colitis which grossly interfere with alimentary function and hence with nutrition. Reports of such association have appeared from time to time,^{1,2} especially in recent years^{3,4} since attention has been drawn to the effects of nutrition on liver injury. In most of the published reports the attempt to relate the cirrhosis or other hepatic lesion to the coexisting colitis is most unconvincing. Each report is based on very few cases, only fifteen having been published to date in the British literature. Moreover, colitis is by no means a rare condition, and it is doubtful whether the figures recorded really indicate a higher incidence of hepatic damage in patients with colitis than might be expected to occur as a result of chance association alone. Thus Tumen and his colleagues⁵ found only five cases of cirrhosis in a series of 151 cases of colitis, an incidence of 3.3%, whereas

Tumen⁵ had himself previously found cirrhosis in 1 to 6% of cadavers at routine necropsies. Johnson's⁶ two cases of hepatic insufficiency revealed by liver function tests were found among 25 cases of colitis, an incidence of 8%, but no confirmation of actual cirrhosis was sought either by biopsy or by peritoneoscopy.

A curious and fallacious argument has been followed by both Johnson and Tumen. They point out that cirrhosis found in association with colitis differs in its age and sex incidence from ordinary cirrhosis, being commoner in women and occurring at a younger age. They therefore conclude that the colitis has been responsible for the development of the cirrhosis, a conclusion that completely overlooks the fact that since colitis has this same age and sex incidence any disease associated with it by chance will of necessity share these same characteristics.

There can be little doubt that gross hepatic cirrhosis recognizable clinically or at necropsy is not a frequent finding in cases of ulcerative colitis, despite the state of chronic malnutrition that is so conspicuous a feature of the condition. This once again emphasizes the fact that cirrhosis is not the result of simple starvation or of insufficient feeding but the consequence of a dietary imbalance, a conclusion also reached by Waterlow⁶ from his recent work on fatty cirrhosis in the West Indies. In the experimental animal cirrhotogenous diets do not lead to severe emaciation but to fat accumulation in the depots and the liver. As severe emaciation is rarely associated with a fatty liver the rarity of the association of cirrhosis with colitis becomes more understandable. Moreover, the persistence of severe fatty infiltration for at least several months is probably necessary before a nutritional cirrhosis is established, whereas colitis is a notoriously intermittent disease in which the slight liver lesions resulting from one relapse may completely disappear during the next remission.

TESTOSTERONE AS A TREATMENT FOR PREMATURITY

The effect of male hormone on the nitrogen metabolism of eunuchoids and castrates has been investigated by a number of workers, and a recent report of Shelton, Varden, and Mark¹ indicates that testosterone might be of therapeutic use in the management of premature infants. A series of 74 babies all under 2,000 grammes was divided into three groups: one a control, one in which the infants received 5 mg. of methyl testosterone daily by mouth, and a third in which the infants received 4 mg. of testosterone propionate intragluteally each day. The time taken to regain the birth weight and subsequently to reach a weight of 2,500 grammes was observed. All the babies receiving testosterone regained their birth weight quicker than the others, but in the group of babies which weighed 1,000 to 1,500 grammes at birth the time taken to reach 2,500 grammes did not differ greatly between those treated and the controls. In the group between the weights of 1,500 to 2,000 grammes, however, the babies receiving testosterone reached the weight of 2,500 grammes more quickly than the controls. No significant differences were observed between the results obtained with testosterone propionate and methyl testosterone. Four sets of premature twins provided the most fully controlled group in the series, one twin being used as a control and the other receiving testosterone. In every case the infant under specific therapy gained weight more rapidly than his twin.

The explanation of these observations would seem to lie in the fact that urinary nitrogen is diminished when

testosterone propionate and methyl testosterone are administered, and at the same time the nitrogen is not raised in the plasma or faeces. It is presumed, therefore, that the diminished nitrogen loss has some significance in relation to the anabolic functions of the body. These drugs also seem to produce a diminution in the urinary volume. The result of their administration is an increase in growth and muscle hypertrophy. Animal experiments indicate that this will take place only in cases where there is a deficiency of the male hormone and that over-saturation will not produce any further increase in the growth process. This view is borne out by the rapid acceleration of the growth process in premature infants during the early days of treatment and the noticeably diminishing effect of testosterone as the babies develop their normal physiological activities. Shelton and his colleagues, who do not of course suggest that the use of male hormone can in any way replace the accepted methods of treating premature infants, did not observe that testosterone caused any toxic reactions or interference with bone growth, and they refer to the work of Gordon and Fields,² who found no instance of premature closure of the epiphyses or of stunting of growth after treating pre-pubertal and adolescent boys for long periods.

ADAPTATIONS TO PHYSICAL TRAINING

It is a characteristic of living organisms that they react towards a disturbance or change of environment in a manner tending to neutralize the effect of the change upon the organism. The property is not definitive, however, partly because purely inorganic systems may display a slight degree of automatic compensation, but also because living organisms can sometimes be observed to react to a disturbance in a manner that, so far from preserving stability, may actually make matters worse. In spite of such exceptions, however, the self-stabilizing quality of living organisms is shown in many ways. A point of great importance is that the response to a disturbance may be, and often is, an amplified response. Two examples may make this clear. A beaker of water has a slight degree of temperature stability, in that the cooling effect of evaporation partly offsets the heating effect of a bunsen burner underneath. But this "response" is only partial. A constant-temperature animal, on the other hand, can secrete water on to its surface for evaporation to a degree which completely offsets the heating of the environment. The survival of a man in dry air at 37° C. depends exclusively on this response, for the basal metabolic rate cannot be lowered far, and indeed is actually higher in such surroundings than in air of somewhat lower temperature. The response to the environment is an amplified response. A hive of bees in their winter cluster responds to lowered environment temperature by an outburst of wing-flapping activity which does not merely lessen the disturbance but actually reverses the temperature change induced by the environment.

This ability of living organisms to make amplified responses carries with it the risk that a response may be over-amplified, and this has an obvious bearing in pathology. It is now 50 years since Welch¹ recognized the fact that pathological "responses" commonly have no survival value for the diseased organism and may even increase the likelihood of fatal termination. Pathological adaptations, which lack, as Welch wrote, "that co-ordinate and special fitness we are accustomed to find in physiological adaptations," may in fact range from "over-amplification"—due perhaps to partial disorganization of the response mechanism—to a

random and irrelevant "response" towards some new and unprecedented disturbing agent.

In a recent paper entitled "A Medical Theory of Gymnastics" Jokl² has emphasized the distinction that must be drawn, not between the adaptive responses of sick and healthy people, but between the response of an individual to a disease-provoking agent and his response to physiological stimuli. Apparently purposeful "adaptations to physical training," he writes, "take place irrespective of whether or not the organism is healthy." Such adaptations he classifies as "structural, dynamic, or integrative," and they are strictly responses to the training—that is, they improve the body's ability to cope with exercise and must not be expected to increase resistance to all disease or to have any influence upon immunological mechanisms.

PARA-AMINOSALICYLIC ACID IN TUBERCULOSIS

In 1940 the biochemist Bernheim¹ made the observation that the oxygen uptake of the tubercle bacillus was stimulated by the two simple substances benzoic acid and salicylic acid. This finding led Lehmann² to investigate a large series of related compounds in the hope of discovering a substance which had a bacteriostatic action against the tubercle bacillus. The most active was *p*-aminosalicylic acid, which in a 10⁻⁵ molar concentration in a medium containing virulent tubercle bacilli caused up to 75% inhibition of growth. Lehmann showed that *p*-aminosalicylic acid was not toxic, and was tolerated by rats when given in quantities which constituted 5% of the daily diet. He also tested its value clinically by applying it locally to tuberculous abscesses and by giving it by mouth to patients with raised temperatures; he observed that the temperature fell and that there was clinical improvement. In this country Davis³ has described the chemical properties of *p*-aminosalicylic acid and the specificity of its bacteriostatic action on the tubercle bacillus, and Martin and his colleagues⁴ have devised a simple method of making the substance and have confirmed Lehmann's opinion of its clinical value, especially in tuberculous empyema. Erdei and Snell⁵ have also reported encouraging results.

Results in small series of cases are sometimes misleading, and the evidence of the curative value of *p*-aminosalicylic acid has been placed on a firmer basis by the observations of Feldman, Karlson, and Hinshaw⁶ in guinea-pigs. They inoculated a group of males with a human type tubercle bacilli, and six weeks later all were seen to be sensitive to an intracutaneous injection of tuberculin. Seventeen animals were then treated with *p*-aminosalicylic acid, given as 4% of the diet, while twenty animals were kept as controls. Treatment lasted 119 days, and at the end of this period sixteen out of the twenty control animals had died. Of the seventeen treated animals only eight had died. Further, the lesions in the control animals which survived were severe, as they were in all but one of those which had died earlier. On the other hand, the lesions were severe in only three of the eight treated animals which died, and it was difficult to account for the death of the other five. Lehmann had said earlier that guinea-pigs tolerate aminosalicylic acid badly, but Feldman and his colleagues seem disinclined to believe this. However that may be, they state that their evidence shows that the power of *p*-aminosalicylic acid to influence favourably a tuberculous infection in guinea-pigs is unmistakable.

FIRST L.C.C. HEALTH CENTRE WOODBERRY DOWN SCHEME

The London County Council this week approved plans submitted by its Health Committee for the building of the first of London's health centres and the first centre in the country to be approved by the Minister of Health. The centre is to be erected on the Council's estate at Woodberry Down, Stoke Newington. Under one roof will be brought ante- and post-natal clinics, a child welfare clinic, a school treatment centre, facilities for other local health services, and for general practitioner and dental services. It will be run in unison with the hospital and specialist services provided by the North-East

Model of L.C.C. Health Centre, Woodberry Down

Metropolitan Regional Hospital Board. Separate consulting- and waiting-rooms are proposed for six doctors. In addition to the ordinary consulting-room accommodation there will be a minor operation unit, similar to that in the out-patients' department of a hospital. Other accommodation will include rooms for specialists, a sterilizing-room, a doctor's laboratory, with a small drug store attached; and it is also proposed to have in attendance a laboratory technician who will be under the control of the pathological laboratory in the district. The doctors will be asked to form a rota for night duty, and there will be sleeping accommodation for the night-duty doctor. There will also be a common-room where the doctors and medical staff of the clinics will be able to forgather and maintain the link which is essential if clinics are to work with N.H.S. doctors in an integrated service.

It is also proposed to have an x-ray department for both general medical and dental examinations, and clerks, nursing attendants, and receptionists will be available for the doctors and dental surgeons working at the centre. It was stated by Mr. I. J. Hayward, the leader of the Council, at a Press conference on the subject, held before the Council's decision, that the doctors would be able to work separately, with an assistant, or in partnership. The partnership arrangement was preferred by the L.C.C. so that they could pool their resources. The patients would have the right to see which doctor they liked, except that in an emergency their own doctor might not be available. Doctors would also be free to make their own arrangements with their patients. Doctors and dental surgeons would be charged what an official of the Council described as an "uneconomic rent" for their accommodation at the centre.

Other features of the centre will be a remedial exercise and a child-guidance unit. A day nursery will be built separately from the centre but on the same site. Accommodation for ophthalmic examination and treatment and an "orthoptic room" are planned.

The Health Committee of the London County Council considers that a neighbourhood unit for health centre purposes should embrace a population of about 20,000. Eventually 162 such centres will be available in the county. At present, however, only one centre is planned for each of the nine divisional areas. This arrangement is considered important because it fits into the school plan for London, and the divisions for health purposes coincide with those for educational purposes. Existing premises will be adapted for health centres in the divisions.

The cost of providing the comprehensive health centre at Woodberry Down is estimated at £187,275. This figure does not include the transfer value of the site or the cost of equipment. Mr. Hayward told the Press conference that his Health Committee believed that it would be the finest health centre in the world and might well be the prototype for others in London and elsewhere.

RECRUITMENT AND TRAINING OF MIDWIVES

WORKING PARTY'S REPORT

The working party, appointed by the Minister of Health, the Secretary of State for Scotland, and the Minister of Labour, in April, 1947, to inquire into the reasons for the shortage of midwives, including in its investigations the problems of recruitment, training, and wastage, published its report¹ on Jan. 28. Describing the midwife as "the practitioner of normal midwifery," the report urges that she should attend the mother and baby for at least a month after delivery. So that midwives should have some hand in shaping that part of the National Health Service with which they are concerned, it is recommended that a maternity services committee, composed of obstetricians, general practitioners, and midwives, should be set up in each hospital region.

It is suggested that there should be a common basic training for nurses and midwives, followed—in the case of midwives—by a year's specialist training with a revised and improved curriculum. Basic training should include at least a four weeks' period in obstetrics. Except for certain special posts there is no need for a midwife to be a State Registered Nurse; but until the new training can be adopted only State Registered Nurses should be trained as midwives. Existing holders of the S.C.M. qualification without a nursing qualification should be eligible for all midwifery appointments. Schools of midwifery, with finance and administration separate from the hospital system, should be set up. Pupil midwives should have student status, and there should be obligatory refresher courses for all practising midwives.

Ranks and Duties

All maternity units of 50 or more beds should be in the charge of an independent matron; units of 30 to 49 beds, a superintendent midwife with the rank of assistant matron; units of fewer than 30 beds, a departmental midwifery sister. The creation of a new rank of senior sister is recommended for those unwilling to give up contact with patients for advancement on the administrative side. On the district every local health authority should appoint as non-medical supervisor of midwives a certified midwife.

The report goes on to recommend that a survey should be made of the distribution of midwives, with inducement payments to attract them to understaffed areas. The number of cases a midwife should deal with should be reduced by 1953 to 55 a year in urban areas instead of 66.4, which was the 1944 average. Except for certain senior ranks the "straight duty" system should be adopted for institutional midwives, and for domiciliary midwives off-duty times and adequate reliefs should be ensured by grouping. Other recommendations include cars for domiciliary midwives; option to live out for institutional staff; and time off for travel and study. Houses should be provided for established midwives, and hostels for junior and pupil midwives.

Allowing for the changing age structure of the profession and the proposed reduction in the case load, recruitment in England and Wales must be increased from 1,790 (the annual average during 1944-7) to 2,100 newly qualified midwives a year by 1953. Special steps should be taken to attract recruits from the 30-45 age group, and part-time workers should be encouraged.

The working party considers that the limited means of analgesia at the midwife's disposal place her at a distinct disadvantage in the face of the growing public demand for relatively painless childbirth. It is suggested that the Medical Research Council should be asked to set up a committee to find a more effective method of analgesia for use by midwives. "Without the addition of this weapon to her armamentarium, the midwife cannot play her proper part in the health team. Furthermore, until this problem is solved the swing away from domiciliary confinement will continue."

¹Report of the Working Party on Midwives. H.M. Stationery Office. Price 2s. 6d., post free 2s. 9d.

Midwives and Doctors

The report includes a postscript on the status of the midwife: "When this report was actually in the press our attention was drawn to many complaints both from medical officers of health and midwives that general practitioners giving maternity service under Part IV of the National Health Service Act are tending to take over the whole of antenatal care as well as relegating midwives to the status of maternity nurses. In some cases midwives are not seeing patients until they go to deliver them. Furthermore, pupils are getting no opportunity to see antenatal care.

"This is entirely contrary to the development of the maternity services as outlined to us by representatives of the Health Department and as envisaged by us. . . . We recognize that it is right that a general practitioner should accept his full responsibility for his patient but not that he should exclude his partner, the midwife, whose function is, we should have thought, well-established and clearly recognized. Moreover, as already stated . . . we are convinced that it is not possible for the present number of doctors to take over complete responsibility for all maternity work in addition to their other commitments, even if this were desirable. As we have said, however, we do not consider it in the patient's interest for either party to monopolize the case. They should work as a team. We hope that prompt administrative action will be taken to stop this new and unwelcome trend which could wreck the structure of the midwifery services."

The working party argues that the assets and liabilities of doctor and midwife are complementary and that the arrangement under the new Health Service, with the two working in partnership, may prove to be a good one. It will be successful, however, only if both parties recognize their partnership. A review of the working of the maternity services in three to five years' time is recommended to ensure that this partnership is being maintained and that "there is no danger of the midwife being ousted from her proper place."

The report reveals that of the 74,219 women on the English Roll of Midwives at March 31, 1947, only 17,095 had notified their intention to practise in 1946. The working party find that many practising midwives are greatly overworked and, that the shortage is due to nurses taking the midwifery qualifications without intending to practise; to the unsatisfactory nature of the present course of training; to the high rate of examination failure; and to lack of promotion prospects.

Reports of Societies

CHELSEA CLINICAL SOCIETY

The fourth dinner meeting of the session was held on Jan. 11 at the South Kensington Hotel, S.W.7, with the president, Mr. Nils Eckhoff, in the chair. "Radioactive Isotopes in Treatment" had been chosen as the subject for a discussion which was conducted by Professor D. W. Smithers and Professor W. V. Mayneord, the latter demonstrating apparatus of a new and advanced type developed for the detection and estimation of radiation. The clear handling of the subject matter was the more appreciated by members in view of its novelty and its potentialities in diagnosis and treatment. A discussion followed in which Drs. Joekes, Jarman, Findlay, and Sir P. Manson Bahr joined, and the speakers replied.

Sir Thomas W. Phillips, Permanent Secretary of the Ministry of National Insurance, retired from the public service on Dec. 31. The Minister of National Insurance, with the approval of the Prime Minister, has appointed Sir Henry D. Hancock to succeed him, and Sir Geoffrey King to fill Sir Henry Hancock's place. Sir Thomas Phillips has been Permanent Secretary of the Ministry of National Insurance since its establishment in November, 1944, and was previously Permanent Secretary of the Ministry of Labour and National Service. Sir Henry Hancock, who is 53, has been Deputy Secretary of the Ministry of National Insurance since 1945, and was previously Deputy Secretary at the Ministry of Supply. Sir Geoffrey King has been in charge of the Industrial Injuries and Family Allowances Schemes in the Ministry of National Insurance since 1946.

Correspondence

Second Thoughts on Proguanil

SIR,—In the leading article under the above title (Jan. 15, p. 106) it was stated that complaints of loss of appetite, reduction of weight, and lack of energy had been received from some of those who had taken proguanil for considerable periods. Reference was made to an article by Schmidt, Hughes, and Smith,¹ who had reported similar signs in the rat, and to three papers published in a recent issue of the *British Journal of Pharmacology* which "have shown that there is almost certainly a pathological basis for these symptoms." The reviewer went on to say that loss of appetite is a matter of moment for Europeans stationed in tropical areas, and that for Africans it is most undesirable that they shall take for long periods a suppressive antimalarial which may reduce still further their already inadequate intake of food.

One of the outstanding advantages of proguanil is that owing to the extremely wide margin between its effective and toxic dosage it is particularly suitable for prophylaxis in general and for both prophylaxis and treatment among indigenous populations of malarious countries. A single-dose treatment of 300 mg. for the clinical attack and a single weekly dose of 300 mg. for prophylaxis have been widely adopted in India, Malaya, and parts of Africa for village dispensary practice and for use among labour forces and indigenous Government employees, with excellent results.

In an extensive series of field trials carried out in India under my direction in 1947 there was never any indication that the administration of proguanil had any adverse effect on the digestive system. Afridi,² who reviewed these trials, drew attention to the fact that many of the more intelligent patients remarked on the feeling of well-being following the taking of the drug. My own experience of a limited series of cases treated at Horton tends to confirm this observation. Large numbers of British troops have been taking 100 mg. of proguanil daily for the prophylaxis of malaria over extended periods, and no reports suggesting an adverse effect on the appetite have yet been forthcoming.

A study of the literature cited by your reviewer reveals the following points:

1. The experiments of Schmidt and his colleagues were confined to the mouse, rat, dog, and monkey. No loss of appetite was noted in monkeys receiving less than 20 mg. proguanil per kg. of body weight daily, which would correspond with a daily dose of 1,300 mg. in a man weighing 65 kg. The maximum prophylactic dosage of proguanil recommended for man is 100 mg. daily for non-immune persons and 300 mg. once weekly for indigenous populations of malarious countries. In summing up their results the authors stress the point that in all the purposes for which proguanil is used it exhibits a greater spread between effective and toxic doses than either chloroquin or mepacrine.

2. It is noteworthy that the investigations recorded in the other three papers cited^{3,4,5} were undertaken in a search for a drug which would inhibit the secretion of gastric juice in the treatment of chronic peptic ulcer. Proguanil was selected for trial because of its known low grade of toxicity. As noted by your reviewer, the desired effect was produced in man when 900 to 1,000 mg. was administered daily, but not with lesser amounts. This dosage is 9 or 10 times as great as the maximum recommended for malaria prophylaxis.

It would be most unfortunate if an impression were to be created, on such slender evidence, that the prophylactic use of proguanil is likely to have an adverse effect on the nutrition of any population to whom it is administered.—I am, etc.,

Epsom.

SIR,—Having recently returned from a nine months' tour of East Africa, the Belgian Congo, and the Rhodesias I was particularly interested to read the articles (Jan. 15, pp. 88 and 91) and the leading article (p. 106) concerning proguanil. At this time (April to December, 1948) proguanil was coming into general clinical use in these territories (although Belgian doctors I encountered in the Congo seemed reluctant to try it), and I made a point of sounding the opinions of the many Government M.O.s, mine doctors, and private practitioners I met from Nairobi to Salisbury about it, while I myself relied for antimalarial protection upon the drug, which I took regularly during the whole of my trip in doses of 0.1 g. thrice weekly, and, although in numerous places where malaria is endemic I was frequently bitten by mosquitoes, I have up till now at any rate managed to avoid developing the disease.

I found that opinions differed widely about the drug, some doctors saying that they had abandoned its use entirely as being unreliable as a prophylactic and unsatisfactory therapeutically, while others contrariwise were its enthusiastic protagonists; this accords with previous experience of the varying susceptibility of the various strains as well as varieties of plasmodia in different areas. I was struck, however, by the frequency with which both protagonists and opponents of proguanil commented on the symptoms of gastro-intestinal disturbances following its exhibition on an empty stomach, and I myself very soon found that to take the drug before meals almost invariably produced nausea and an extremely unpleasant epigastric pain, which, however, never appeared when I took it after food.—I am, etc.

MICHAEL BOSTOCK

Infective Ear Disease

SIR,—Mr. T. A. Clarke's letter (Jan. 15, p. 111) on the treatment of chronic suppurative otitis media calls for some comment. If the object of ear toilet is to remove from the external canal any debris and discharge that may act as a nidus of infection and interfere with drainage from the middle ear, such treatment is most likely to be effective if carried out as often as the discharge reaccumulates. It is probable that the chronic running ear, which is the bane of so many E.N.T. out-patient departments, would in many cases respond to the intensive daily treatment which it is usually only possible to give in institutional practice. As Mr. Clarke points out, good results with conservative methods can only be expected in uncomplicated cases. Otoscopic appearances, however, may sometimes be misleading. An antero-inferior perforation, though suggestive of simple tubal infection, may coexist with extensive mastoiditis. X rays, which Mr. Clarke decries, may prove of the greatest value in revealing or excluding latent disease in the cellular type of mastoid.

It is difficult to see what benefit can arise from "largely filling the meatus" with powder, following ear toilet. This practice, though often adopted, results in a hard plug which interferes with the free drainage which it is the object of treatment to promote, and may cause irritation to the meatal wall. Neither penicillin nor sulphathiazole has any bactericidal action against the organisms commonly responsible for chronic otitis media. It should be a *sine qua non* of any preparation used locally in middle-ear disease not only that it exerts an action against the organisms concerned but also that it will promote drainage and healing and is capable of reaching the infected area. Drops containing urea 20% as an organic solvent and ephedrine 1% in solution with an effective bactericide may be massaged into the middle ear after meatal toilet, and in many cases where the eustachian tube is patent will be tasted in the throat.

I have recently undertaken bacteriological tests on a series of cases of chronic ear disease with a view to determining what bactericide would be most satisfactory for routine use. It was found that 90% of swabs grew *Ps. pyocyanea*, often associated with *Proteus vulgaris* and various diphtheroids. Strains of *Ps. pyocyanea* were therefore isolated in pure culture, and many substances, including those commonly used in the treatment of aural sepsis, were tested for their power to inhibit the growth of this notoriously resistant organism. By far the most effective bactericide, as demonstrated by serial dilution and by diffusion on agar, was found to be tinct. "merthiolate" (1 in 1,000). This preparation was shown by similar methods to be active against *Proteus vulgaris*. Of other substances tested only acetic

acid 1% exerted a comparable action against *Ps. pyocyanea* on agar. It was, however, noted that mild silver proteinate (10%), which inhibited growth in dilution but diffused poorly on the agar plate, could be rendered considerably more effective by the addition of a wetting agent such as "drefit" (or one of the higher sulphonated alcohols) to lower the surface tension.—I am, etc.,

Woolwich.

D. C. SEUTE.

SIR,—I have been most interested to read Mr. Colin M. Johnston's report (Dec. 18, 1948, p. 1049) on infective ear disease in factory employees. Conditions affecting the external ear have interested me for some time past, and all too seldom have comprehensive investigations into these painful and time-wasting conditions been reported. For too long a time has interest, both lay and professional, been lacking in attaining an understanding of the aetiology, pathology, and treatment of external ear diseases. I find myself in full agreement with the author, and am glad to see that he stresses more than once the constant care and patience that are required by both patient and doctor if a reasonable hope of cure is entertained.

An important point, but often forgotten, is to remove pus and debris from the meatus, and indeed, if this is practised often and thoroughly enough, a cure can be had without resort to any further medicaments: this applies particularly in the mild chronic cases. He also mentions the importance of cleaning out the recess between the inferior wall of the meatus and the tympanic membrane, for it is here that infective debris can hide and be a constant source of trouble.

A far more alert consciousness of these simple ear affections is required, and it is encouraging to see that the attempt to stimulate this consciousness has already begun.—I am, etc.,

Halifax, Nova Scotia.

GEOFFREY FRENCH.

Approach to the Frontal Lobe

SIR,—Most readers will by now be acquainted with a surgical incision into the brain to alter the mental state of a psychotic patient. This technique (leucotomy or lobotomy) and its results have been discussed in medical journals, and some of its aspects have been communicated to the general public by the daily press and wireless.

While research workers and clinicians are still struggling to disentangle the results produced by present methods for leucotomy, a new access for the destruction of frontal lobe tissue is being recommended by Freeman in the U.S.A. A spike is introduced through the orbit, and by piercing the orbital roof of the frontal bone it causes injury to the orbital surface of the frontal lobe among other structures. While this procedure adds another "dark approach" to the frontal lobe, more serious consequences, such as a possible opening of a large frontal sinus, which can lead to meningitis, uncontrollable haemorrhage, and pushing bone fragments of the thin orbital roof into the brain, have to be faced.

What predictable results can be achieved with this method? Present knowledge of the frontal lobe does not as yet permit of advice being given to the neurosurgeon as to whether he should destroy dorsal or orbital portions of the frontal lobe or their connexions. As long as there is not a rational basis for the "older methods" the new approach can certainly not be defended as being better, and the possible complications make its usefulness highly questionable.

It is, however, a matter of some urgency that the indications for a leucotomy operation should be clearly defined by a united effort of research and clinical observation. Otherwise psychiatry, so much in need of methods of curing, will look back with regret on the period of "leucotomizing," possible only as the frontal lobe is a "silent area" to some extent and does not object to surgical incision by obvious motor or sensory defects.—I am etc.,

Oxford.

P. GLEES.

Psychiatry and Broadcasting

SIR,—It appears that the public, having had a surfeit of psychological films, are now to be treated in like manner by the radio. While the entertainment value of these broadcasts may be high, there are other considerations which are equally important. For example, in one programme the history of a delusion was traced, although inadequately, and it was implied

that over-sensitivity in childhood was conducive to the development of a chronic psychotic state with a hopeless prognosis. What it failed to stress was that the chronic psychotics of all types hardly number one per thousand of the population, and that the case described is relatively scarce in a mental hospital. This omission produced considerable anxiety among my out-patients, many of whose original fears of insanity were reinforced.

Again, in a recent broadcast concerning prefrontal leucotomy accuracy was sacrificed for a good script. No mention was made of W. E. Le Gros Clark's views¹ that the progressive enlargement of the frontal lobes in the phylogenetic scale is by no means as conspicuous as that of the parietal or temporal lobes. Psychotherapists are familiar with some patients' insistence on surgical intervention, and as long as these requests were confined to the abdomen a reasoned approach could convince the patient that the problem was psychogenic and that the mind required treatment. This explanation is now countered with a request for a brain operation, and it is difficult to persuade the patient in the face of B.B.C. "propaganda" that many psychiatrists consider that the only redeeming feature about prefrontal leucotomy is that it confines itself to the "silent area."

Inaccurate and misleading statements on medical matters often appear in the lay press, but with this important difference: the prestige of the writer's name is withheld. I am not suggesting that anonymity would be a solution, but wish to point out that there is a different procedure for the radio, without any apparent reason. The problem is a very important one, and merits the attention of responsible medical opinion.—I am, etc.,

Plasma-cell Mastitis

SIR,—It is interesting to note that Mr. John M. Jackson's letter (Jan. 8, p. 71) on "comedomastitis" is followed a week later by an article by Dr. Max Cutler on "plasma-cell mastitis" (Jan. 15, p. 94). From the macroscopic description it seems possible that Mr. Jackson's cases were examples of plasma-cell mastitis. It seems that plasma-cell mastitis is not such an uncommon condition, and more cases will be found if the lesion is kept in mind. The discovery of five cases in 1,500 consecutive breast examinations by Parsons and his colleagues¹ supports this view.

My purpose in writing to you, however, is not to add to the cases recorded in the literature but to suggest that the names given to the condition so far have been unfortunate. We have, as you note in your annotation (Jan. 15, p. 108), been cursed since König's time by the term "chronic mastitis" and we would gladly be done with it if we could find a term generally acceptable. I would suggest with Atkins² that fibro-adenosis is as good as any.

The use of the inflammatory suffix may be more justified in the plasma-cell lesion, for it is probably a tissue reaction to lipid substances extravasated from the ducts, and is, in some ways, comparable to traumatic fat necrosis. It may even be a virus disease. On the other hand, until the aetiology is definitely known it seems unnecessary to give it a name which makes a preconceived idea of its cause unavoidable. The plasma cell is not even a pathognomonic feature, as it is also found in fat necrosis. I would suggest that the term mastopathy means as much as mastitis in our present state of knowledge and commits us not at all. Incidentally, the tendency to refer to "comedocarcinoma" and "comedomastitis" might well be turned to the older and more scientific terminology of Robert Muir, "intraduct carcinoma" and, on the same analogy, "intraduct mastitis."—I am, etc.,

Glasgow.

Spinal Analgesia with Cinchocaine Hydrochloride

SIR,—Your correspondent, Dr. N. Beattie, in his letter on spinal analgesia and caesarean section (Jan. 15, p. 114), is in error in using the word "percaïne." After a number of fatal accidents nearly ten years ago in which "percaïne" had been

confused with procaine, the makers renamed the drug "nupercaine." Mr. Beattie aggravates the matter by referring once to percaïne, once to nupercaine, and once to "percaïne (or nupercaine)," as though they were different drugs.

There have been several recent injection errors; a fatal case was reported in the lay press but a few days ago. To prevent more of these accidents we must be strictly exact in our terminology, especially when contributing to a medical journal which is read by people of all grades of experience.—I am, etc.,

Newcastle-upon-Tyne.

M. H. ARMSTRONG DAVISON.

Treatment of Abortus Fever

SIR,—May I dissociate myself from the views expressed by my ex-house-physician, Dr. R. O. Parnis (Dec. 18, 1948, p. 1082)? It is true that sulphadiazine often brings down the temperature in undulant fever and seems to abort the pyrexial wave, but comparison of a series of 100 cases treated by sulphadiazine with a similar series of untreated controls did not show any significant difference as regards the total duration of the fever.

Undulant fever is so erratic in its behaviour that it is foolish, to attempt to draw any conclusions from a small number of cases. An unfortunately extensive experience has moderated my early impulsiveness to rush into print and has made me somewhat sceptical of the "cures" which are reported from time to time. I still keep an open mind and live in the hope that a really specific remedy will be found at last, but I am not convinced that sulphadiazine alone or in combination with transfusion or streptomycin is the answer.

Another point I would like to draw attention to is that experiments *in vitro* are not always applicable *in vivo*. The main difficulty is not to find a substance which will kill the brucella, but to get at the micro-organism. The possibility that the brucella may find a refuge within the body cells has already been hinted at—in any case it seems to entrench itself impreguably in the spleen and in the bone marrow.—I am, etc.,

Valletta, Malta.

J. E. DEBONO.

Belladonna Liniment Causing Mydriasis

SIR,—I think it desirable to draw the attention of the profession to the need for giving a warning about the danger to the eyes when liniments containing belladonna are prescribed. Textbooks that I have consulted fail to give this. For the lack of it the drug may inadvertently affect the eyes of either the patient or the applier of the liniment. The following case, therefore, seems to me of general interest.

A female patient of 55 was sent to me by her doctor because the right pupil was dilated. I found it inactive to light; it did not contract with prolonged convergence. The left pupil was active both directly and consensually. The patient was right-handed. She said that she had been applying a liniment to her husband, who was subject to rheumatism. She denied that she had applied any drops or other medicament to her eye. The doctor wrote on inquiry that he had prescribed a liniment containing aconite, belladonna, and chloroform. The circumstantial evidence seems to warrant the conclusion that some belladonna from the liniment had been conveyed to the eye by the right hand. Unilateral mydriasis had resulted. Fortunately the tension as tested by the fingers was not raised.

HUMPHREY N. FAME.

Antihistamine Drugs and Erythroblastosis

SIR,—Valuable advances in the treatment of infants suffering from haemolytic disease of the newborn have been made since the discovery of the Rhesus group of antigens and its significance in these cases. The case mortality has been greatly lowered, but there is still no certain means of preventing the disease, although various measures to achieve this have been advocated from time to time.

The recent work on the possible value of the antihistamines in the treatment of various diseases, to which you refer in your leading article entitled "Allergy, Rheumatic Fever, and Nephritis" (Jan. 1, p. 21), has prompted us to plan an investigation into the possibility of preventing haemolytic disease of the foetus and newborn (erythroblastosis foetalis) by the administration of antihistamine substances during pregnancy to women who appear likely on general or serological grounds to give birth to affected infants.

It may be that the clinical and pathological manifestations of haemolytic disease of the foetus and newborn are initiated by the release of histamine, heparin, and possibly other as yet unidentified substances following the antigen-antibody reaction between the various Rhesus-factor group-specific substances and their several antibody globulins. The precise origin and intimate mode of release of histamine is not known with certainty even in many conditions for which there is substantial evidence that it is concerned.

If the antihistamines do not prove of value in this connexion, this may possibly shed some light on the pathogenesis of haemolytic disease of the foetus and newborn. Antihistamines may also have a place in the management of haemolytic transfusion reactions, and this is being investigated at this depot as and when opportunity presents.

Although antihistamines produce side reactions such as drowsiness in some individuals, they are not so far as is known toxic substances and are unlikely to harm the mother or foetus. It is hoped to present the results of the investigation now in progress as soon as a sufficiently large series has been collected to make a statistically satisfactory assessment possible, but there is nothing to be lost by their use on a purely empirical basis, preferably in close collaboration with an experienced blood group serologist or the nearest regional blood transfusion officer.—I am, etc.,

South London Blood Supply Depot,
Sutton, Surrey.

R. H. TRINICK.

Diagnosis of Tuberculous Meningitis

SIR.—With reference to Dr. J. T. Lewis's letter (Dec. 11, 1948, p. 1036) regarding the sugar and chloride levels found in tuberculous meningitis, I have been asked to send you the findings of the subcommittee of pathologists engaged in the Ministry of Health scheme which was begun in the autumn of 1947.

Reports received in April, 1948, showed that, of 223 cases in which the chloride content of the first specimen of cerebrospinal fluid was estimated, 34 (15%) gave a figure of 700 mg. of NaCl per 100 ml. or more and 88 (39%) a level of more than 650 mg.; of the 88 only 3 were unconfirmed by film or culture, and 2 of these are dead. As regards prognosis, cases have been reported in which the original chloride was less than 600 mg. but which after streptomycin treatment were clinically well and with fluids normal in all respects. The subcommittee therefore considers that estimation of chloride content is useless in the diagnosis and prognosis of tuberculous meningitis and that treatment may be unjustifiably delayed if reliance is placed on the test.

In 137 cases in which the sugar content of the first sample was estimated the figure was never more than 50 mg. per 100 ml. As Dr. Lewis insists, this test is of much greater value than the chloride estimation.—I am, etc.,

London, E.1.

F. C. O. VALENTINE.

Cardiac Arrest

SIR.—I read with great interest the memorandum by Mr. G. P. Charlewood (Dec. 11, 1948, p. 1023) on a modified technique of cardiac massage in cardiac arrest. I had occasion to use a similar procedure some six months ago. As in Mr. Charlewood's case I found Hamilton Bailey's manoeuvre unsuccessful, but, as soon as I got my fingers inside the pericardium and was able to massage the heart directly, the beats began again. The case history was as follows.

The patient was an old man, 82 years of age, admitted with an acute or chronic large-bowel obstruction due to a constricting carcinoma of the pelvi-rectal junction. His abdomen was distended, and he was very toxic. It was proposed to perform a transverse colostomy using local anaesthetic and "pentothal" narcosis. The anaesthetist had just injected the initial dose of pentothal, when he became worried about the patient's condition and found the heart had stopped. He called for cardiac massage.

An upper midline incision was rapidly performed, and a bare right hand thrust into the abdomen and an endeavour made to perform cardiac massage by compressing the heart rhythmically against the anterior chest wall, without result. Therefore, with a pair of Mayo scissors, an opening was made in the diaphragmatic pericardium and the thumb and two fingers of the right hand thrust through. The ventricles were gripped firmly and rhythmically squeezed. Very soon one or two faint flutters were felt, and then vigorous rapid beats recommenced. A rapid transverse colostomy was performed and the abdomen closed, but the heart rate became

more rapid and feeble and finally ceased altogether half an hour after it had begun to beat again. This I imagine was due to the age and toxicity of the patient.

I can see no contraindication for this manoeuvre of incising the diaphragmatic pericardium. It is rapidly and easily performed with Mayo scissors, and it would appear to be unnecessary to repair the incision, as the upper surface of the left lobe of the liver, by adhering to the diaphragm, will close the linear hole. It seems to be the only method of massaging the heart directly and effectively.—I am, etc.,

London, E.C.1.

ERIC M. NANSON.

Intussusception Due to Carcinoma of Colon

SIR.—In view of the correspondence which followed the publication of Mr. R. A. C. Owen's account (Oct. 30, 1948, p. 786) of two cases of intussusception due to carcinoma of the colon, the following case report may be of interest.

The patient was a man aged 72. He had a three months' history of increasing constipation alternating with diarrhoea. He had some abdominal pain, but no vomiting. There was sudden relief from the abdominal pain on the day before admission. On admission his temperature was 99.6° F. (37.5° C.) and his pulse was 100. He was a pale, well-preserved old man. His tongue was dry, brown, and furred, and the fetor oris was present. His abdomen was very tense, with generalized distension, tympanitis, and borborygmi. There was no demonstrable free fluid and no viscera were palpable.

On rectal examination a soft lump could be felt free in the lumen of the bowel. It was not friable, and there was no bleeding. Proctoscopy showed the lump to be oedematous and ulcerated. A diagnosis was made of complete intestinal obstruction due to polypoid tumour of the rectum, and intussusception was suspected.

At operation the peritoneal cavity was found to contain gas and fluid faeces. There was an intussusception of the pelvic colon into the rectum, with dilatation of the proximal colon and perforation of the caecum. Decompression of the large bowel by ileocaecostomy was carried out and the intussusception was easily reduced. A small dimple at the apex (the site of ulceration) was left, and near the apex could be felt a small firm lump. The pelvic colon was mobilized and the affected gut resected (Paul's operation).

The tumour was a small, rounded, sessile papillomatous mass, 2.54 cm. in diameter. There was no apparent involvement of the adjacent wall or glands. The pathologist reported that it was a tubular, polygonal-celled carcinoma. The patient was discharged in good condition 72 days after admission. Abdominal wounds were healed; there was a slight ooze from the caecostomy site.

I have to thank Dr. C. D. Coyle, Medical Superintendent of the Archway Group of Hospitals, for permission to publish details of this case.

—I am, etc.,

London, N.19.

W. C. TURNER.

Prescription of Barbiturates

SIR.—The letter by Dr. A. I. Suchett-Kaye on barbiturate poisoning (Dec. 11, 1948, p. 1035) and the one on prescription of barbiturates by Dr. T. Pearce Williams (p. 1036) are instructive. It is obviously dangerous to hand such strong narcotic drugs to people without having full control over the quantity taken by them in one dose. This danger existed since the introduction of barbiturates into therapy. In order to minimize the danger of poisoning—not infrequent already many years ago—the teaching of pharmacology at the University of Budapest, where I was a student before the first world war, contained the wise suggestion for the addition of pulvis ipecacuanhae to every dose of barbiturate prescribed, in a small enough dose not to cause vomiting in the normal individual. It was pointed out that an overdose of barbiturate will, thus prescribed, also contain an overdose of ipecacuanha, which will produce vomiting. I believe that this information will be of interest to all who took part in the correspondence and to all those who are interested in this subject.—I am, etc.,

Johannesburg, S. Africa.

NATHAN FENN.

Marxist Genetics

SIR.—It is easy for Dr. Geoffrey Bourne (Jan. 1, p. 28) to say that my remarks (Dec. 11, 1948, p. 1038) were beside the point, as he makes his own decision about what my point was. I was very careful to make it clear that my concern was with the propagandist way in which Dr. Darlington misrepresented the work of Lysenko, which he was supposed to be reviewing. Every sentence in my letter was relevant to this.

Several other readers—anti- as well as pro-Lysenko—have written on the same issue. I did not deny that Lysenko considers philosophy, science, and politics to be interrelated. The whole point of this correspondence, until Dr. Bourne tried to change it, was the question of Dr. Darlington's review, not primarily Lysenko. And no one has answered to the point for Dr. Darlington.—I am, etc.,

London, S.E.24.

H. M. ROSE.

SIR,—I have followed your correspondence since Dr. C. D. Darlington's review (Nov. 13, 1948, p. 862) of *Soviet Biology* with great interest. I think the criticisms made of that review are fully justified. Some of your correspondents, however, have chosen to indulge in yet other vituperations. Fortunately ample material is available to answer them.

Dr. John C. C. Langford (Dec. 11, p. 1038) would like to know if the opposition to Lysenko was "prearranged" or not. It certainly was not. Those who opposed various aspects of Lysenko's views have been doing so for the past 10–15 years; their criticisms were sincere and forthright, and were based on the writings and works of those concerned. They evidently had no fear of Dr. Darlington's "liquidation." The full text of the contributions of Zembrak, Polyakov, Zavadovsky, Roubin, and Schmalhausen are contained in a translation for the Engels Society. Summaries of the rest will be found in *Plant Breeding Abstracts* (1948, 18, No. 2,000). The force of Zavadovsky's argument may be gathered from the following:

"As a Darwinist I agree with T. D. Lysenko, and the other comrades who have taken part in the discussion, as to their general statements on the enormous decisive significance of conditions of environment and its influences in the processes of forming the breed and the kind. And yet there are still a large number of problems of supreme significance on which I do not agree with T. D. Lysenko. . . .

"As I have already remarked, I affirm that his report and the discussion of it are leading our public to a one-sided conception of the situation and distribution of forces in Soviet biology. We scientists are explorers not only in the question of the concrete application of our experience and knowledge in order to investigate the geological womb and other riches of our socialist land. We are explorers also with regard to the correct orientation as to the distribution of forces in our science. And here I think Comrade Lysenko is making a serious mistake by taking the line of there being only two fronts or two trends in biological science, which have as their aim the solution of the problem of Darwinism."

Professor Zavadovsky goes on to elaborate his point of view in great detail. Professor Polyakov deprecates the tendency to label Soviet scientists as "Morganist" or with similar titles because they fail to agree with Lysenko. But quotations are entirely inadequate. Read the material in full, and one will doubt the integrity or sincerity of Lysenko's critics. Dr. Langford's notion effects nothing but to ridicule those who do not agree with Lysenko. I hope he will realize the pettiness of his suggestion.

One further point: Dr. Geoffrey Bourne's implication (Jan. 1, p. 28) that the application of dialectical materialism to science is necessarily bad is simply untrue. It is best answered by example. Based on dialectical materialism is Lysenko's theory of phasic development; this came from his work on vernalization and may well lead to further methods for hurrying plants through various stages of their development. B. A. Roubin, director of the Bach Biochemical Institute, records work in which it is shown that some enzymes in plants change their activity optima in correspondence with changing phases of development, thus adding experimental support to the phasic theory. Professor C. H. Waddington (*New Statesman and Nation*, Jan. 1, 1949, p. 6) admits that "his (Lysenko's) phasic theory, and the even more explicitly dialectical theory of another Russian, Krenke, on the cyclical alternation of senescence and rejuvenescence in plants, are certainly far from negligible contributions to the theory of organic development." Krenke's theory already finds practical application in a method of judging the optimum time at which to harvest sugar-beet based on leaf shape (Ashby, E., *Scientist in Russia*, Pelican Books, 1947). It seems to me that a dialectical approach to biological problems is more in accord with biological data than a mechanistic or idealistic one.—I am, etc.,

Cambridge.

PETER A. JEWELL.

Calcified Cyst of Spleen

SIR,—I read with interest Mr. J. H. Donovan's article (Dec. 25, 1948, p. 1106) on calcified cyst of the spleen, and also a further communication by Dr. A. Elkeles (Jan. 8, p. 74). In your *Journal* of March 4, 1933 (p. 367), I myself reported in full (together with a plate) a case of calcified cyst of the spleen, reaching the same conclusions as Mr. Donovan and Dr. Elkeles. Following the publication of my article I had several letters written to me concerning similar cases, and I consider the condition is probably not quite so rare as has been suggested by the present writers.—I am, etc.,

Manchester.

F. H. SCOTSON.

Achlorhydria Following Gastro-enteritis

SIR,—The prevailing gastro-enteritis (not attributable to any particular food or drink) is very often followed by an achlorhydria. The symptoms are vague pains, very often below the sternum and along the left side of the abdomen, loss of appetite, and general loss of well-being. In an elderly person it may simulate gastric or duodenal carcinoma.

A typical case was a man of 57 admitted for suspected carcinoma of stomach, his chief complaint being anorexia. Barium meal on two occasions failed to show signs of neoplasm. A fractional test-meal revealed the presence of histamine-fast achlorhydria. The occult-blood test was negative; haemoglobin, 105%. His symptoms could be traced back to an attack of gastro-enteritis some weeks earlier. A second patient was an 8-year-old girl. She complained of pains in the stomach at night; her appetite was poor, and she was losing weight; she had had gastro-enteritis two to three weeks earlier.

The symptoms may go on for many weeks. They are cured by acid. hydrochlor. dil. given before meals (with an appetizer like gentian). I have met many such cases in the past.—I am, etc.,

Billingshurst, Sussex.

JOSEPH VINE.

Perforated Duodenal Ulcer in a Boy

SIR,—I feel the following case deserves publication on account of the youth of the patient.

A boy, aged 14, collapsed in school at midday on Dec. 9, 1948, and was admitted to hospital forthwith. He complained of severe abdominal pain, was very shocked, and had to be treated for some time with heat and morphine. His abdomen was rigid from peritonitis due to perforation of an anterior duodenal ulcer of fairly long standing. Under thiopentone with gas, oxygen, and ether, operation was performed by me at 4 p.m., and the perforation was closed with difficulty. The abdomen was cleaned out by sucker and closed without drainage. Next morning a Rylo's tube was passed and drip-fed intravenous dextrose and saline was set going, both for two days only. He threatened to be chesty and had penicillin by injection for three days. The patient gave no further trouble and was discharged on Jan. 3, 1949.

This case is remarkable on account of the extreme youth of the patient and the fact that he was symptom-free, although his ulcer was not recent.—I am, etc.,

Huntley, Aberdeenshire.

PETER W. PHILIP.

Carcinoma of the Male Breast

SIR,—I have been interested in reading Sir Cecil Wakeley's article on carcinoma of the breast and its treatment (Oct. 2, 1948, p. 631). One small point in the article has troubled me, and I should be glad if you were to clarify it for me. In speaking on mammary carcinoma in the male Sir Cecil says, "The prognosis of carcinoma in the male breast is very poor; the small undeveloped breast allows early lymphatic spread before the condition is diagnosed."

I am unable to understand this. I had thought that were an organ "small and undeveloped" its lymphatic drainage would be poorer, actually and potentially, especially since the male breast, unlike its sister, is at no time normally subjected to alternating periods of growth and atrophy. Similarly the male breast is much less vascular than the female breast. Sir Cecil writes, "In girls and young women the vascularity of the breast is very pronounced, and if carcinoma develops, the prognosis is hopeless." Furthermore, Sir Cecil himself suggests a different aetiology for the male condition, and this is most feasible,

as the male breast is not subjected as a rule to the slings and arrows of hormonal interplay, balance, and imbalance in a degree comparable with that in the female breast.

Is it not then, Sir, more logical to suppose that carcinoma of the male breast is an entity distinct from female mammary carcinoma, of possibly different aetiology, and displaying a tendency to earlier metastasis than its feminine counterpart?—I am, etc.,

Thursday Island.

W. T. GIBBS.

Epilepsy and Foetal Behaviour

SIR,—Professor F. J. Nattrass's Lumleian Lectures (Jan. 1, p. 1, and Jan. 8, p. 43), together with your leading article entitled "Epilepsy" (Jan. 8, p. 61), prompt me to ask the following question: Is it altogether absurd to suggest that in the epileptic fit there is a reversion to the foetal level of nervous functioning, an idea that was first put forward 30 years ago by L. Pierce Clark in America? Apart from Hughlings Jackson's theory that the phenomena which follow a fit reflect a reversal of nervous evolution, there are three points which might support such a possibility. They are: (1) That during a fit behaviour becomes "total," in the sense that the whole of the skeletal musculature is thrown into action simultaneously. According to the Coghill school of physiology the "total" response represents the most primitive pattern of behaviour. (2) That the movements in the idiopathic fit are of two types—viz., tonic and clonic. These seem to compare with the "sustained" and "jerky" movements described by Sir Joseph Barcroft as occurring in the sheep foetus. (3) That the movements in the fit are spastic in type, as they appear to be in the foetus.—I am, etc.,

Brentwood, Essex.

THOMAS D. POWER.

Purpura Complicating Pregnancy

SIR,—Dr. I. Klass (Jan. 8, p. 73) disagrees with some of the conclusions which I reach in my paper "Purpura Haemorrhagica as a Complication of Pregnancy" (Dec. 11, 1948, p. 1020), but in both my paper and that of Drs. Burnett and Klass stress is laid on the fact that the mortality of purpura complicating pregnancy has been overstated and that recovery does occur, as in the cases which we have respectively recorded.

I agree that some of the earlier cases reported were not of true purpura, as Dr. Klass has shown in his paper, but only 22 cases are included in this analysis, and it is impossible to say how many of the remaining 46 cases reported up to that time suffered from true purpura. It is unreasonable, therefore, to assume that purpura is not a fatal condition on the basis of an analysis of less than one-third of the reported cases. Certain of the cases not included in his analysis, for instance that of Puech referred to in my paper, strongly suggest that death has resulted from a true purpura leading to prolonged late post-partum haemorrhage.

In the case reported by Drs. Burnett and Klass the platelet count at the onset of symptoms was very low (15,000 per c.mm.), but this rose after 35 weeks to 163,000. At delivery a figure of 76,000 was noted, but the placental blood showed 121,000 platelets, and when recovery was complete the figure given is 174,000. It seems, therefore, that even in health the platelet count in this patient tended to be low, and that on the basis of the figures given she had attained a large measure of recovery before delivery. The case in fact was a relatively transient one comparable to, although more severe than, my own, and it is to this and not to any essential harmlessness of the condition that the absence of bleeding from the uterus and from the perineal tear is due.

Dr. Klass considers the treatment has little influence on the condition and that there is nothing in the literature to form any basis for dogmatic principles of treatment. This opinion is based on his analysis, as we have seen, of only a small proportion of the recorded cases, and particularly upon the experience of his own case, where, as I have pointed out above, the platelet count was five times higher at delivery than at the onset of symptoms and about half the highest level ever recorded in this patient. Purpura must be regarded as a disease potentially dangerous. While in the immediate control of haemorrhage after delivery efficient uterine contraction remains the most important factor, this should be followed by adequate clotting

to give prolonged haemostasis, and where there is any question about this, as there must be in cases which show purpuric eruptions and thrombopenia during pregnancy, it is unfair to one's patient to neglect any measure which can ensure her safety.—I am, etc.,

INVERNESS.

J. A. CHALMERS.

Overdose of Surface Analgesics

SIR,—Mr. C. A. Jackson's article on amethocaine hydrochloride (Jan. 15, p. 99) directs attention to the dangers associated with amethocaine surface analgesia for bronchoscopy, but it would be of interest to know precisely how many patients die yearly as a result of the surface application of analgesic drugs; it is probable that all the effective ones are equally dangerous. Two points require emphasis. One is that overdose is presumably determined not by the total amount of the drug absorbed over a period but by the concentration in the brain at any given moment. When this concentration reaches the appropriate level signs of overdose will occur. The second point is that prompt treatment should save the patient; treatment of the severe case consists in controlling the convulsions in order to permit of oxygenation.

The alarming convulsions due to severe overdose with an analgesic drug do not appear to differ from those seen in ether convulsions. In a case treated by the writer following the instillation of 10% cocaine hydrochloride for urethral instrumentation the convulsions were so severe that it required great force to hold the arm in order to give thiopentone intravenously. Meanwhile attempts were made to insufflate oxygen under pressure, and as soon as the thiopentone was given the convulsions ceased and normal colour was restored. There were no after effects.

Great caution is certainly necessary in using local analgesic drugs for bronchoscopy in asthmatics. In a bad chronic asthmatic subject I applied 10% cocaine hydrochloride, spraying the pharynx and larynx with about 2 ml. and spraying about 1 ml. into the trachea by passing the tube of the spray between the cords. The patient immediately complained of breathlessness and became excited. Thiopentone was given at once, 0.3 g. being injected slowly, and oxygen was given under pressure. The surgeon proceeded with the bronchoscopy, but a further 0.2 g. of thiopentone was necessary to control coughing. There were no more signs of cocaineism. The surgeon aspirated much mucus and noted that the bronchi were red and injected. Recovery after the bronchoscopy was prolonged, and it was necessary to give oxygen under pressure for more than half an hour in order to avoid cyanosis; mucus kept welling up from the trachea, due probably to bronchial spasm caused by the thiopentone. No analeptic was given, and the cough reflex finally returned and the patient was sent back to the ward. There was no more difficulty.

—I am, etc.,

Luton.

D. WILSON

Meeting of Medical Association of South Africa

SIR,—The Medical Association of South Africa will hold its 37th annual Congress in Capetown during the week Sept. 19–24, 1949, and the Organizing Committee extends a warm welcome to any members of the British Medical Association or any other medical practitioner who may wish to attend.

A visit to South Africa at this time will afford an opportunity to be present at the meetings of Congress, with discussions not only in the many scientific departments of medicine but also in matters of medical policy, particularly the development of national health schemes and hospital legislation, which so vitally affect the future of the medical profession in Great Britain and the Dominions. There is an urgent demand for interchange of views and experiences by informed representatives and for the framing of basic principles for future action to the advantage of the citizens of the Empire and for the protection of the legitimate interests of the medical profession. Furthermore, the scenic attractions of the subcontinent should make the journey worth while to those who extend their stay, as well as the opportunity to observe the rapid development of the country and to obtain some understanding of the difficult social problems—not unaffected by world turbulence, particularly in the East—which the Union must endeavour to solve.

The journey to South Africa by sea is a fair-weather voyage. The mailships from Southampton take 14 days to cover the 6,000 miles. More economic transport takes a few days longer. By air to Capetown from London is about three days, unfolding an infinitely varied geographical panorama of this vast continent.

It is emphasized that accommodation in Capetown is limited, and prospective visitors to Congress are advised to apply to the Hon. Secretary, 37th S.A. Medical Congress, P.O. Box 643, Capetown, at their earliest convenience for hotel reservations and any other information.—I am, etc.,

T. LINDSAY SANDES,
President of Congress.

Capetown.

Master Minds

SIR,—My attention has been drawn to a letter under the above title from Mr. Fred Messer, M.P. (Jan. 15, p. 115). Challenging the accuracy of a *Hendon and Finchley Times* report of his speech at a Golders Green meeting of the North-west Branch of the Socialist Medical Association, Mr. Messer suggests that certain remarks attributed to him were in fact made by other speakers.

I have inspected the notes taken by our reporter. They contain a clear record of the remarks in question, with no room for confusion with other speakers. In point of fact, our reporter was too busy that night to remain at the meeting for long after Mr. Messer's own speech.

It is a point of interest that Mr. Messer, in his original letter to the Middlesex Local Medical Committee, did not question the accuracy of our record as such, but relied upon the age-old explanation in political circles—that a passage in his address "had been torn from the context."

Regarding Mr. Messer's closing paragraph, I would point out that nowhere in our report did the word "politics" occur.—I am, etc.,

BARRETT NEWBERY,
Editor, *Hendon and Finchley Times*.

POINTS FROM LETTERS

Clouding of Surgeons' Spectacles

Dr. C. EDWARDS (Bournemouth) writes: In reference to the correspondence on this subject, why do surgeons not wear their spectacles outside their masks? Many years ago whilst in active surgical practice I got Mr. Crighton, of Winchester, to make me a pair of less strength (0.5 sph.) than my reading glasses—i.e., for middle-length reading—tilted down and with rather longer curl wire sides so that the frame lay near the tip of the nose. Result, perfect.

Antihistamine Drug Treatment of Acute Nephritis

Dr. WALTER BROADBENT (Henfield, Sussex) writes: This seems to be a very important advance in the treatment of a disease which often causes irreparable damage. In the past I used to give antistreptococcal serum, 10 ml. by the mouth every night apart from food, to children with acute nephritis. This did materially shorten the attacks, but not so effectively as "anthisan" evidently does.

Whooping-cough and Measles

Dr. F. ROTHENBURGH (Widnes) writes: Referring to Dr. C. L. Malhotra's note (Jan. 15, p. 116) on whooping-cough and measles, I wish to point out that measles may start with severe pertussiform cough or may be followed by a similar attack. This pertussiform cough has of course nothing to do with a real pertussis infection and is due to an enlargement of the intrathoracic glands, particularly the tracheo-bronchial and paratracheal ones.

House Numbering

Dr. P. T. T. MACDONALD (Bristol) writes: I have not, to my surprise, seen in the *British Medical Journal* any complaint respecting the matter of house numbering in urban areas. In my own district, which I believe is not exceptional, the state of matters is almost beyond belief and seems to indicate the absence of any civic responsibility for whether a house is numbered or not, and, if numbered, whether the numbers are easily legible from the roadway or not. This condition of affairs is a constant source of irritation and loss of time in the day and night work of our profession—nurses as well as doctors being hampered by it. . . . To remedy this nuisance the application of such a standard of numbering as is demanded of motorists for their cars should not be too difficult a matter. At any rate I am airing my grievance in the hope of fellow sufferers doing likewise and of inducing responsible authorities to do something about it.

Obituary

C. F. GOOD, C.B., M.R.C.S., L.R.C.P.

The death of Dr. Christopher Frank Good on Jan. 16, at the age of 56, removes from the medical staff of the Ministry of Health one of its most outstanding figures. He was a man with a fund of common sense, sterling qualities, and a broad outlook, a man who can ill be spared at the present time. He had a remarkable faculty for grasping the essentials of any problem.

Good was one of a large family, four of whom entered the medical profession. Born in London, he received his medical training at the London Hospital. His record during the first world war was characteristic. Against advice and while in his fourth year he joined a Red Cross unit as a dresser and served abroad for about a year. Returning to England he enlisted as a combatant and obtained a commission in the Buffs. He saw service in France, received a severe gunshot wound of the chest in 1917, and was subsequently demobilized in 1918. It was a delight to listen to him recounting his experiences during this period. Returning to the London Hospital he qualified M.R.C.S., L.R.C.P. in 1919 and then held a series of house appointments there. After a short period during which he was associated with the Ministry of Pensions he settled in a busy private practice in Battersea and in 1931 was appointed to the regional medical staff of the Ministry of Health. Here his administrative abilities were quickly recognized and for a period he was seconded to the headquarters staff for certain special investigations.

The prospect of war in 1938 made it necessary for the Ministry to engage in a survey of hospital accommodation in the country and to make plans for enlarging this accommodation where necessary, adapting it for wartime needs, and generally providing for an integrated hospital service which would stand the stress of total war. Good was appointed as hospital officer in charge of this work for the North East Civil Defence Region, and from his labours there emerged an organization which worked smoothly and was invariably able to meet the many demands put upon it. The value of this work and the sound foundations on which it was based can perhaps be fully appreciated only by the hospitals, medical officers of health, and others with whom he came in contact. When in 1940 it became necessary to fill a vacancy as principal regional medical officer in the North East Region, Good was given this appointment, and though his experience in public health was at that time limited his period of office proved an outstanding success.

Towards the end of the war Good returned to Whitehall, where he helped in the preparation of the hospital survey reports and particularly the one associated with the North East Region. This was also a time when preparatory work was being done on the Health Service, and very soon he became closely associated with that part of the scheme in which his great interest lay—general practice. In 1945 he was appointed principal medical officer in charge of the medical section of the Ministry dealing with general practitioner services and insurance, which post he held until his death. The high regard in which he was held and the reputation he had already established made it possible for him to wield great influence where the general practitioner services were concerned. The Insurance Regional Medical Service, of which he was also in charge, was revived in 1945, and much of his time during the past two years was taken up in starting again the referee functions of this service and in adapting it to meet the needs of the Ministry of National Insurance. Good was ever mindful of the welfare of members of the regional medical staff. All his colleagues held him in the highest esteem and his passing will be to them in particular a great loss. In recognition of his outstanding service with the Ministry he was awarded the C.B. in 1948.

Whilst in Leeds Good underwent a serious operation, after which he was well aware that the possibility of complete recovery was remote. Subsequent developments confirmed this unfavourable view, and although periods of treatment in hospital were remarkably successful in arresting the disease, he fully realized that the inevitable outcome was only a matter of time.

His courage in facing this prospect was a source of admiration to all who knew him, and required a pluck and philosophy which it is given to few mortals to possess. He will long be remembered by those who were privileged to work with him for his vivid personality, humanity, sparkling conversation, and dauntless courage. He leaves a widow to whom the sincere sympathy of all who worked with him is extended.

H. S. SULLIVAN, M.D.

Dr. Harry Stack Sullivan, who died in Paris on Jan. 14, was a distinguished American psychiatrist, chairman of the Council of Fellows of the Washington School of Psychiatry, editor of *Psychiatry*, and author of much valuable work, especially in his earlier days, on schizophrenia and later on the subject of interpersonal relationships. Dr. Sullivan was born in 1892, and graduated at Chicago in 1917. When America came into the recent war, Dr. Sullivan acted as consulting psychiatrist to the Office of Selective Service in the United States. He advised on the general mechanism for psychiatric and psychological sifting of those called up for the Army. He had been active in many fields despite the fact that he had suffered from several cardiac attacks. His death was the result of yet one more cardiac accident.

Dr. Sullivan, who was in London last summer for the International Congress on Mental Health, and who worked extremely hard previously on the International Preparatory Commission which he himself had originated, moved on to further work as psychiatric consultant in the American zone of Germany and lectured in various parts of Europe before returning to Washington. He flew over at the beginning of this month to Amsterdam, where for a week he worked hard on the Advisory Committee of the World Federation for Mental Health and at meetings of its Executive Board. He had gone on to Paris to help in a conference with Unesco before returning home. His death will be greatly regretted by many people in Europe as well as by his relatives and professional colleagues in the United States.

MR. SIBERT FORREST ANTROBUS COWELL, who was secretary of the Royal College of Surgeons of England for many years, died at St. Albans on Jan. 13 at the age of 85. Mr. Cowell, who was the son of Dr. Thomas William Cowell, went to Westminster School in 1876 and became a Queen's scholar three years later. He graduated in 1886 from University College, Oxford, after gaining a third-class in Classical Moderations and a fourth-class in "Greats." He became assistant secretary of the College in 1888, and succeeded Edward Trimmer as secretary in 1901. His whole life was devoted to the College from the time of his first appointment until his retirement under the age limit in 1934.

Universities and Colleges

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The following lectures will be delivered at the College (Lincoln's Inn Fields, London, W.C.), at 5 p.m. on each day: Feb. 2, Hunterian Lecture by Professor Terence Cawthorne, "Some Observations on the Pathology and Surgical Treatment of Labyrinthine Vertigo of Non-infective Origin"; Feb. 7, Hunterian Lecture by Professor R. W. Raven, "The Properties and Surgical Problems of Malignant Melanoma"; Feb. 9, Moynihan Lecture by Sir Henry Cohen, "Hypoglycaemia and Hyperinsulinism"; Feb. 10, Hunterian Lecture by Professor Michael Oldfield, "Advances in Hare-lip and Cleft Palate Surgery, following the Treatment of 500 Patients"; Feb. 14, Hunterian Oration by Mr. H. S. Souttar, "John Hunter—The Observer"; Feb. 17, Hunterian Lecture by Professor J. G. Bonnin, "Diastasis of the Tibio-fibular Syndesmosis"; Feb. 21, Hunterian Lecture by Professor D. F. Ellison Nash, "The Development of Micturition Control"; Feb. 23, Hunterian Lecture by Professor W. S. Lewin, "Acute Subdural and Extradural Haematoma in Closed Head Injuries"; Feb. 24, Hunterian Lecture by Professor Robert Roaf, "The Treatment of Residual Disability following Injuries of the Peripheral Nerves of the Upper Extremity"; Feb. 28, Hunterian Lecture by Professor R. A. Russell Taylor, "The Aetiology, Pathology, Diagnosis, and Treatment of Acute Pancreatitis: a Review of 110 Cases." The lectures are open to those attending courses in the College and also to all other medical practitioners, dental surgeons, and advanced students.

Medical Notes in Parliament

DEBATE ON N.H.S.

A debate on anomalies arising out of the National Health Service Act was opened on Jan. 21 by Sir HENRY MORRIS-JONES. He regretted that Mr. Bevan was absent and said that that was the first opportunity which the House had had of discussing matters arising under the regulations of an Act intimately touching every household. That Mr. Bevan was not present to deal with these matters was rather an affront to the House. It was right that the Ministry should be negotiating with the British Medical Association and other interested bodies, but the House was entitled to know what was going on. Sir Henry pointed out that the cost of the Health Service was £30,000,000 over the estimate. Responsible authorities said it might go to £100,000,000 above the estimate in the next year or two. He thought the Act would survive its teething troubles, but the House should inquire where redress could be secured within the regulations without initiating further Acts of Parliament.

Large numbers of medical men were unhappy about the position and the working of the Act. Their work had increased in all areas. Medical men in large industrial areas had gained somewhat, in some areas by as much as 25 to 30%. In all other areas, residential, rural, and seaside resorts, remuneration had gone down, in some respects so seriously as to affect the morale and working power of the general practitioner. He quoted a letter from a firm of medical men in a seaside resort who had 4,000 patients on their panel at 16s. a head. This gave a gross income of £3,200 a year. Practice expenses for the current year amounted to £1,950, leaving £416 for each of the three partners before deduction of tax. Consultations and visits averaged 90 per day for the last six months. The net pay per attendance, after practice expenses were deducted, was 9d. This did not include consultations by telephone, estimated at 20 per day. The senior partner in the firm wrote that "the Health Service in this area is being soured at the point of contact between patient and doctor." Sir Henry was glad that the Minister had made a fairly substantial concession in rural areas. A man in a rural area with a panel of 1,000 was often harder worked than a man in an industrial area with a panel of 4,000. Many doctors in rural areas were threatened at present with financial ruin: they could not meet their commitments. The whole basis of remuneration should be reconsidered. If they could not get good service under this head the whole Act failed. Much was to be said for payment per attendance, with power for the State to make a grant in aid. A commission in New Zealand had recently reported in favour of the suggestion. In any State scheme there was bound to be a greater demand on the Service, although people in Britain had, on the whole, behaved very well.

Basic Salary

The basic salary arrangement was really not working at all. Liverpool had granted it, but other large cities in Lancashire had not. Llandudno had granted it, but Colwyn Bay refused it. In the County of Caernarvon the basic salary was paid, but in Derbyshire only three out of 32 doctors who applied for it had been granted the basic salary. Parliament had intended the basic salary to be paid. Distribution of medical men was worse than it ever had been, because medical men and women were "frozen" in their areas and could not leave them. If medical men in a seaside resort found that their incomes were reduced, or did not want to spend their lives attending nervous and elderly people, they could not go elsewhere. Maldistribution, of which Mr. Bevan had made so much in his speeches to the House, was intensified at present. At Deganwy, between Llandudno and Colwyn Bay, the people had been refused a medical man by the executive council, although there had been one practising there for seventy years. Why should the people have to go two miles away, where many had to wait all day to see a practitioner? In many cases young medical men were not allowed to start in new areas. When they made an inquiry they were told they would not be allowed to settle there unless they had accommodation. Having secured it, they were still not sure they would be allowed to settle there. The purpose of the Act was thus being frustrated.

Turning to the facilities given to foreign visitors to have free treatment under the Act, Sir Henry asked why a temporary visitor should be allowed to get treatment and equipment for nothing. A wealthy Belgian could come to this country and get medical treatment, but there was no reciprocity. Sir Henry did not suggest that members of the Commonwealth should be excluded from these facilities. The question of specialists needed reviewing. Many specialists found their incomes had

been drastically reduced. An orthopaedic surgeon in the provinces had told Sir Henry that he had made thousands a year but that his income had been reduced to £1,200 a year as an allowance from the State for his hospital work. He was considering seriously whether he could carry on in his profession. In some directions, said Sir Henry, economies could be effected. In some London hospitals administrative blocks were being built up at great expense, whereas nothing was being done about the actual equipment. Money was being spent on building blocks for administrative purposes but not for the doctors and nurses. The Minister must get the hearty co-operation of the general practitioners in working the Act. If that was secured, the measure had a wonderful future. But if the doctors were put in a state of financial anxiety and worry their interest in their work would go and the health of the people would suffer.

Complete Co-operation

Mr. MESSER said that in day-to-day experience of the administration of this Service he found complete co-operation from every section of the medical profession. He agreed with Sir Henry Morris-Jones that the Service stood or fell on the co-operation of the medical profession. Out of a mass of contradictions and anomalies a pattern had to be formed. As a supporter of the Service, Mr. Messer agreed that great hardship was being experienced by many general practitioners. The attention of the executive council of which he was a member had been drawn to instances where doctors' incomes had been reduced from a range of £2,000 to £1,500 a year. That executive council entrusted to a medical committee—that was, to the doctors themselves—the distribution of the basic salary. When asked whether a basic salary was desired the medical committee had said that it was not. Mr. Messer suggested that the negotiations which preceded the Act and reached a compromise were responsible for much of the existing difficulties. The situation could not remain where it was. To say more about what was proceeding at the moment would be to divulge confidences.

It was not a weakness of the Service that much more treatment was being given. This indicated what the country had previously lacked. In joining the administration of voluntary hospitals and municipal hospitals they had to avoid the fragmentation of the former and the over-centralization of the latter. It was necessary to set up an administrative machine with the inevitable danger that the number of staff required might be exaggerated. That, too, would have to be investigated, but he argued that they should give the scheme a longer trial than six months. That time was insufficient to decide what major changes should be made. There were not enough specialists. They should organize the Service so that the specialist would have the maximum amount of time in the place where he was most required.

Many Anomalies

Mr. LINSTED remarked that the Act of 1946 attempted to go too far and too fast. Many anomalies could have been avoided if the advance had been by evolution rather than by revolution. The Service was on the rails and moving, but it was creaking and groaning. Mr. Bevan would have to come to the House to ask for more money. That would be the occasion for a full debate. The dental situation had got completely out of hand. Secrecy still surrounded the remuneration of specialists, although a limited number of people had seen the Spens Report. There had been long delay in the payment of chemists' accounts. He asked when the amending Bill would be produced. The matter of medical partnerships could not be settled till this Bill was produced. As soon as possible the Ministry, in its dealings with the hospitals, should indicate its long-term policy over capital projects. If hospitals were put off from year to year, not knowing when a project was to be sanctioned, they were in a difficult position. He hoped it would be possible to work the capital side of hospital finances on the same lines as university finances, at least for quinquennial periods. He knew of institutions which claimed to be homes and not hospitals. They did not know whether they should have been taken over on the appointed day. Section 9 (8) of the Act gave the Minister power to make regulations for determining such cases by arbitration. Had the Minister yet made arbitration regulations? How many applications for arbitration had been made and with what results? Staffs of such institutions should be given another date by which to choose whether to carry on under the old conditions or to accept the new National Health Service conditions.

Mr. Linstead referred to the difficulty in which hospital management committees were put through the activities of nursing agencies. Owing to the shortage of nurses, qualified

nurses were joining the agencies and getting paid, in some cases, twice as much as they would receive under "Rushcliffe." A newly qualified nurse walked out of her hospital, joined an agency, and stayed as a full-time resident nurse at the hospital at twice the negotiated salary for perhaps a year. That made difficulty for the hospital and a strain among nurses.

Improvement in Health

Dr. HADEN GUEST said an enormous saving had begun to accrue in improvement in the health of the people. It was correct that the remuneration of practitioners in large industrial areas had increased. That included the greater part of the practitioners of the country. That applied to areas round London which were not commonly regarded as industrial, such as Mitcham. A solution would be found to the problem of doctors near the retiring age who had settled in places such as Worthing and were in serious difficulties through the abolition of fee-paying practices. It would be a complicated solution, a problem for the local organizations, and the same treatment would not be applied in all areas. In rural areas fees could not be calculated on the amount of time given to patients; they must be averaged out. He did not think the Exchequer would lose a large sum by the free medical treatment of foreigners temporarily resident. As chairman of the Medical Priority Committee he knew there were not enough specialists. An increase of 50% was needed to staff the hospitals properly. There was a deficiency of specialists in the eastern counties, in many other places, and in the armed Forces. In view of the shortage of nurses he suggested that the Government should put out the people who ran nursing agencies and bring these nurses into a nursing service.

Mr. ASSHETON said there were bound to be great difficulties when the scheme was first put into operation, but a number could have been avoided. He asked whether the medical profession did not find itself much overworked and with insufficient time to give to serious illness. Did the people who needed them most get the beds in the hospitals? Was there any possibility of avoiding great delays in getting hospital accommodation? Queues at surgeries had grown enormously. Was it not possible to give doctors more help in dealing with work which was not strictly medical? On Dec. 16 Mr. Bevan had said he had received statements of hospitals' probable expenditure for the current year but that none had yet been approved. Was that still the situation? There was a feeling that a large number of doctors were worse off in remuneration than they were before and that doctors were worse off than any other class of professional men or women in the scheme. The remuneration of dentists would have to be discussed on a later occasion.

Government Reply

Replying to the debate, Mr. JOHN EDWARDS said the Parliamentary Secretary was expected to deal with administrative reviews made on a motion for the adjournment of the House. The National Health Service had been welcomed by all classes to an extent beyond expectations. About 40,000,000 persons had placed their names on doctors' lists. The percentage of the population in the scheme would be 95 to 98. He was talking of England and Wales, not of Scotland, and was certain the proportion would be at least 95%. Out of an estimated total of about 21,000 general practitioners, 18,165 had come into the scheme. These doctors had already prescribed 75,000,000 medicines or appliances since the Service began. Out of 10,000 dentists in general practice 8,988 had entered the Service and had treated 2,200,000 patients, with 1,200,000 under treatment. It seemed that the peak in the demand for dentists' services had passed, but the demand ran at the rate of 130,000 a week. More than 2,500,000 people had had their sight tested under the supplementary ophthalmic service, and over 3,000,000 pairs of glasses were on order. The pent-up demand for such things was much greater than the Ministry had foreseen. As the rush was beginning to subside, the Ministry of Health was taking steps to review every side of the Service.

Remuneration

Remuneration was among the matters which the Ministry was considering. He reminded the House that the arrangements which had been made had in many cases not been those which the Ministry thought, in the first place, to be right. The arrangement by which the bulk of the fee was to be paid in the form of so much per person on the doctor's list had been made at the request of the profession. Taking everything into account, payments to doctors under the G.P. part of the scheme, from the appointed day to March 31, 1949, were estimated at £32,500,000. In additional Exchequer superannuation contributions were £11,600,000 extra. That overall amount would ensure that doctors would be remunerated in accordance

PLAIN TALKS ON INFANT FEEDING

Taken for Granted

When the mother is unable to feed her child from the breast, is it not too easily taken for granted, by her busy and often hard-driven advisers, that cow's milk, in one form or another, is a satisfactory substitute — cow's milk of course with modification? The point to emphasise here is the modification. The young human stomach cannot cope with the quantity or the toughness of the casein in cow's milk. Simply to dry the cow's milk and add vitamins is not enough. The constituents of cow's milk must be scientifically broken down and reconstituted so that the percentages of components are as near as possible to the percentages found in the mother's milk. Not only this, but the components must be reconstituted in a state so refined that the infant can assimilate them easily. Trufood has approximately the same quantities of fat, carbohydrate and protein as human milk. But the greater part of the insoluble casein in cow's milk which causes the child most trouble in digestion, has been removed. This is why we are able to say that Humanised Trufood is the nearest to human milk — and also why, when they realise the difference, so many doctors recommend it.

In later advertisements we propose to explain other reasons, and we venture to hope that doctors and others concerned with infant feeding will do us the honour of re-examining this important matter. Literature giving detailed information can be obtained by writing to Trufood Ltd. (Dept. B M.36), Bebington, Wirral, Cheshire.

Issued by the Makers of Trufood —

NEAREST TO MOTHER'S MILK

*'when everything
seems to go wrong...'*

People today, harassed and run down, find themselves unable to contend with all the small irritations and minor mishaps of life.

Livogen is invaluable in all cases of nervous depression, reduced vitality and general debility. It restores vitality rationally, by supplementing the normal resources of the body. It is a balanced composition of liquid extract of liver B.P., extract of yeast, vitamin B₁ and nicotinic acid. Bottles of 4 and 16 fluid ounces are available as well as bottles of 80 fluid ounces for dispensing. Literature is available to medical men on request.

with the Spens recommendations. Distribution had been uneven partly from administrative difficulties and partly because of a certain amount of inflation in doctors' lists. He hoped that they would have eliminated this element of inflation and have got down to firm figures so that final payments could be made at the end of March, 1949, with all necessary adjustments. He recognized that the position of the rural doctor was difficult. Under the National Health Insurance scheme mileage allowances had helped the rural doctor to meet the extra costs of travel and so on. He was also able, if so minded, to charge higher fees to private patients in rural areas. Some time ago the Ministry had agreed with the profession that it would increase the mileage payments to £1,300,000 to cover ineffective time spent in travelling by rural doctors. It was clear that amount would not suffice. The Government therefore had agreed to provide a further £500,000 a year and to divert £200,000 from the inducement money in the Bill, giving a total mileage fund of £2,000,000 a year for Great Britain.

At this stage the full effect of maternity fees had not shown itself in doctors' remuneration. When final payments were made for the period from July 5, 1948, to March 31, 1949, if the remuneration of general practitioners did not accord with the Spens recommendations the arrangements would be reviewed to see what adjustments were needed to give effect to those recommendations. In the matter of basic salary the Minister had done precisely what the profession had wanted him to do. If anything was wrong, the doctors should go to their own Association rather than tell the Ministry that they had begun to change their minds. Although he had no detailed information about the number of basic salaries granted by local executive councils, the Ministry some time ago had a figure of 1,000 cases in which it had been granted. The Ministry had advised executive councils to give consideration to applications for a basic salary where there was reasonable justification. The Ministry had instanced a doctor starting a new practice or working a small practice; a doctor who on account of ill-health or of age was unable to do as much as he would otherwise do; and doctors whose incomes had dropped substantially as a result of the new Service. The difficulties were inherent in the system which the Ministry had adopted at the request of the profession.

Distribution of Doctors

On the difficulties about the distribution of doctors Mr. Edwards said the Central Medical Practices Committee had indicated that they would sympathetically consider an application from a doctor to live and practise at Deganwy, but that no application had been received. It was wrong to say nothing had been done about the maldistribution of doctors. Since the appointed day 530 general practitioners had died or resigned from the medical list and 532 new doctors had been admitted to the list. Of the 530 vacancies, 230 were filled by a partner, an assistant, or a person who seemed the logical successor. In 238 cases no successor was thought to be necessary because the outgoing doctor had only a small list. In 62 cases the vacancy had been advertised and a selection had been made from applicants. Normally it took from two and a half to three months to fill a vacancy. If a vacancy was advertised it was open to anyone to apply. He said that so far Chester and Hastings were the only areas which had been closed completely. In some places small parts of districts had been closed. The Medical Practices Committee would soon be able to give a better indication of the under-doctored areas. They were studying reports from all the executive councils. He knew of no way of separating foreign visitors except by introducing an elaborate new administrative technique. He could not tell when the Amending Bill would be introduced.

Time did not permit him to elaborate on the capital side of hospital finance, but apportionment on transfer regulations had been made on May 1, 1948 (S.I. No. 888). A panel of arbitrators had been set up by the Lord Chancellor under Mr. Christie, K.C. There were six requests to go to arbitration, five received about the appointed day and one in the week preceding this debate. The five were carrying on as before, pending the arbitration. The Ministry had difficulties in deciding the right course to take with the sixth case. It had settled a number of legal points and hoped to refer the first case to the panel in the following week. Mr. Edwards agreed that the problem of the co-operative nursing agencies required careful consideration. It was bound up with the discussions going on in the Whitley Council concerning nurses' remuneration. Estimates of hospital expenditure had not been approved but did not apply till the beginning of April. The Ministry must have time to co-ordinate this business. He knew there were long delays in securing hospital beds. They were still dreadfully short of nurses. It ought to be the rule throughout the country that beds were allocated in accordance with medical need.

There should be no way in which the genuinely medically urgent case could be by-passed by less urgent cases in a private pay-block or anywhere else.

There was no doubt that some sections of the medical profession were much overworked. He wished it were possible to give them some help. Plan as they might, and much as they might rely on the regional boards and management committees, in the end the scheme would succeed or fail in accordance with the degree to which the Ministry obtained the skill and devotion of those who worked it. He looked forward to improving the scheme, in which there were, no doubt, still a number of anomalies.

Cottage Hospitals

Mr. H. SUTCLIFFE on Jan. 18 opened a debate on the taking over by the State under the National Health Service Act of hospitals which had been privately endowed by the generosity of an individual. He said that Dr. Kershaw, of Royton, who died in 1909, had left the residue of his estate to trustees to be applied to the founding, establishment, and maintenance of a general hospital or infirmary in the township of Royton on land owned by him. The hospital was to be free and open to all applicants. The first world war delayed the building of the hospital, but it was ready for opening by 1930. The Charity Commissioners had approved the scheme according to the terms of Dr. Kershaw's will. The hospital cost £20,000 to build, leaving an endowment fund of £67,000, which had now reached £71,000 because of interest and one or two other legacies. Not a penny had been collected through the rates or in any other way and there had never been a flag day. The endowment fund was sufficient to fulfil all the purposes of the hospital, which was a self-contained unit of 19 beds where patients could receive treatment at as low a cost as 5s. a week in some cases. A weekly payment of 10s. had been usual. People came to it from surrounding districts as well as from Royton. The Charity Commissioners had vested control in a committee of nine which was thoroughly representative. The Commissioners had added that a minister of religion or a person professing Socialist opinions was not eligible to be a member of the committee. That provision was in strict compliance with Dr. Kershaw's will. The committee had expected that the hospital would be disclaimed under Clause 6 (3) of the National Health Service Act, but on Sept. 24, 1947, it had received a letter from the Minister stating that Mr. Bevan was of opinion that the hospital was transferable. The committee applied to be disclaimed, but heard nothing until March 11, 1948, when a letter arrived which stated that the Minister had decided not to disclaim the hospital.

Mr. Sutcliffe understood that in the Manchester area sixteen hospitals had been disclaimed and he thought that Royton should have been. He contrasted the position under the Education (Miscellaneous Provisions) Act, 1948, whereby the assent of the Charity Commissioners was needed before the Minister took over any endowment which had been in existence less than fifty years. He asked for reconsideration of the position of these hospitals and suggested that the Minister had an opportunity to alter procedure by regulation. He also asked what was the future of the Royton hospital, which was fully equipped and had a fine operating theatre. Only half a dozen patients were now in it, whereas before the Act came into force the beds were nearly always full and there was often a waiting-list. People needing operations were being sent elsewhere because the operating theatre at that hospital was no longer used. He hoped that the Royton hospital would not suffer the same fate as the Yorkshire Home for Incurables at Harrogate, where there were seventy beds and an endowment fund of £100,000. The committee of that hospital had been cajoled into coming in under the scheme by the threat that they would find it difficult to get nurses if they remained outside. Instead of that institution continuing as a hospital it was used as the finance department of the local hospital board. Instead of people being admitted from a long waiting-list the whole building had become offices. Action of that kind made people apprehensive of the future. He hoped that the Minister would at least say that the Royton hospital would continue to be used to full capacity as a hospital.

Mr. JOHN EDWARDS, Parliamentary Secretary to the Ministry of Health, said it was true that the hospital service of the country had been largely built up by private benefactions, and at the time of the passing of the Act everyone knew that large numbers of voluntary hospitals would be taken over and that provision must be made for what would happen to their endowments. This particular hospital did not differ from hundreds of other privately endowed voluntary hospitals which were taken over on the appointed day. The hospital had been administered under a scheme for which the Charity Commissioners were responsible and the Commissioners did not in

any way oppose the transfer. The question the Minister had to decide under the Act was whether the hospital was required for the new Service. With regard to the delay in considering the application that the hospital should be disclaimed, Mr. Edwards said the Ministry did not take each request as it was received but waited until all the requests were in hand and until they had consulted the regional hospital boards. It appeared to the Ministry that the hospital ought to be transferred because it was needed in the new Service, and the regional hospital board expressed the same view. Of the sixteen hospitals which had been disclaimed in the Manchester region not one could be compared with the Royton hospital, because they were either run by religious bodies or were institutions which the Ministry did not want. If it were said that this hospital was needed by the people of Royton the Minister of Health was responsible for providing the health services in Royton and had there a well-equipped cottage hospital which was essentially part of that provision.

The Royton hospital would not serve the neighbourhood less efficiently within the new Service. It was likely to become of greater service than if it remained a solitary isolated institution. He assured the people of Royton that this was their hospital and that it was still essential for them to take an interest in it. The general intentions of Dr. Kershaw would be maintained, and the management committee were under an obligation to have regard to the past purposes of the hospital in determining its future use. The hospital management committee or the regional board was not entitled to divert it to other uses unless it was absolutely clear that the services needed by the neighbourhood would be provided in other ways. The hospital would be used as a cottage hospital as in the past. If Dr. Kershaw had intended that there should be no racial, religious, or political discrimination, that intention should be fulfilled. There was no likelihood of such discrimination in a hospital for which the regional board was responsible to the Minister, who in turn was responsible to the House. Without speculating about the long-distant future, the present intention was to use the hospital as a cottage hospital.

Service in the Forces

Answering questions on Jan. 18, Mr. ISAACS said there would this year be four registrations for National Service: on Feb. 26, May 21, Sept. 3, and Dec. 3. After registration, medical examinations would spread over the following three months. The age of call-up would remain at a little above 18 years and 3 months. If young men at school wished to be called up early to their period of service with the beginning of courses at the universities in the autumn of any year, their request would be granted.

Agenized Flour

Sir ERNEST GRAHAM-LITTLE asked whether Mr. Strachey knew that the use of agene for bleaching flour provided for human consumption had been prohibited in the U.S.A. in accordance with the advice tendered by the Food and Drug Administration, and what steps he was taking to prevent the use of agene in this country.

Mr. STRACHEY replied on Jan. 20 that the use of nitrogen trichloride was to be discontinued in the U.S.A. on Aug. 1. A small scientific committee under the chairmanship of Sir Wilson Jameson, Chief Medical Officer of the Ministry of Health, had been set up and was reviewing the results of experimental work on flour improvers now in progress in the United Kingdom and the data submitted in evidence at Washington.

Chelsea Hospital for Women.—Commander NOBLE asked on Jan. 20 whether the Minister of Health was aware that the secretary of the Chelsea Hospital for Women had been dismissed by the new board of governors of this joint hospital after twenty-six years' hospital service, eleven as secretary of this hospital, and with only eight years to do for pension. Mr. BEVAN understood that the new board of governors decided, as they were entitled to do, to appoint a new secretary for their hospitals. He added that the officer could apply for the other posts. The National Health Service Act provided for compensation of transferred officers who suffered loss attributable to the passing of the Act.

Emergency Dentistry.—Mr. BEVAN told Mr. PROCTOR on Jan. 20 that a simplified procedure was being devised to assist dentists to deal expeditiously with emergency cases. The dental organizations had also been asked to arrange with dentists in the National Health Service to reserve a short period daily to deal with emergency cases.

From Feb. 1 Rampton and Moss Side State Institutions will be known respectively as: Rampton Hospital for Mental Defectives, Reford, Notts; and Moss Side Hospital for Mental Defectives, Maghull, near Liverpool.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Jan. 8.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Food Poisoning at Boston

On Jan. 20 there was an outbreak of food poisoning at the Carlton Road School, Boston, Lincs. This consists of an infants and a seniors department, and children from Witham Green School attend the dinner centre at Carlton Road.

Children affected had eaten a midday meal which had been prepared by the civic restaurant. At first it appeared that about 50 children had been taken ill, with vomiting as the main symptom. One child when first seen at school was lying across her desk, had had a sharp attack of vomiting, and had a pulse rate about 100. After admission to hospital she stated that she began to vomit because she had seen the other children vomit, but in fact she had had dinner at home.

No anxiety was felt for any of the 7 cases suffering from food poisoning and admitted to hospital. Diarrhoea was not a marked feature, two children only having diarrhoea after admission. An average pulse rate was about 100 to 110 and of poor quality. One child was febrile— 101° F.—but was subsequently noted to be suffering from bronchial catarrh. The children progressed very satisfactorily, and on Jan. 22 none of them was complaining. There was no evidence of prostration or collapse.

Specimens of bilious vomit were taken at school, together with a specimen of gravy and three fishcakes left over from the midday meal.

The meal in question consisted of fishcakes, vegetables, and fruit pie. The type of outbreak and the short interval between the meal and onset of symptoms suggested that the cause was pre-formed toxin. Altogether 66 cases were referred for treatment, two of these being adults, one a member of the teaching staff and the other a helper at the centre. Recovery appears to have been rapid in every case. Laboratory investigations are not yet complete, though a large growth of staphylococci was obtained from the fishcakes.

Vital Statistics for 1948

The Registrar-General's weekly return for the week ended Jan. 15 records that the total number of deaths registered in England and Wales during 1948 was 470,282—the lowest number for eighteen years despite an increase of some $3\frac{1}{2}$ millions in the population at risk. This represents a record low death rate of 10.8 per 1,000 total population, an improvement of 1.2 over that for 1947; the previous lowest rate was 11.4 in 1945 and 1930. There were 26,635 deaths of children under one year of age in 1948, giving a rate of 34 per 1,000 related live births. This is the first time the annual rate has fallen below 40, the previous lowest being 41 in the previous year. The rate for the December quarter of 1948 was 35, the lowest for any fourth quarter. Stillbirths numbered only 18,415, giving a rate of 23.1 per 1,000 live and still births. This is the lowest rate ever recorded for any year, the previous lowest being 24.1 in 1947. The rate for the December quarter was 22.9, being also the lowest for any fourth quarter.

The number of live births registered in England and Wales was 777,648, a reduction of 109,172 from the peak of 886,820 in 1947, but still substantially above pre-war levels—for example, 621,204 in 1938. In the following table the numbers and corresponding rates of live births, stillbirths, deaths, and deaths of children under one year of age registered during the fourth quarter and the year 1948 are compared with those for the fourth quarters and the years 1947, 1946, and 1938:

	Live Births		Stillbirths		Deaths (including Non-civilians)		Deaths of Infants Under 1 Year	
	No.	Per 1,000 Total Population	No.	Per 1,000 Total Live and Still-births	No.	Per 1,000 Total Population	No.	Per 1,000 Live Births
4th quarter, 1948	179,680	16.4	4,206	22.9	125,557	11.5	6,473	35
" " 1947	193,586	17.8	4,665	23.5	120,765	11.1	7,952	38
" " 1946	221,815	20.6	6,115	26.8	122,546	11.4	9,147	43
" " 1938	143,756	13.8	5,833	39	119,366	11.5	7,504	49
Year, 1948	777,648	17.9	18,415	23.1	470,282	10.8	26,635	34
" " 1947	886,820	20.6	21,916	24.1	517,615	12	36,849	41
" " 1946	819,894	19.2	22,915	27.2	492,090	11.5	33,541	43
" " 1938	621,204	15.1	24,729	38.3	478,996	11.6	32,724	53

Discussion of Table

In England and Wales increases were recorded in the notifications of measles 2,064, whooping-cough 291, acute pneumonia

131, and dysentery 28. There were decreases in the incidence of scarlet fever 103 and diphtheria 16.

For the second consecutive week an increase of over 2,000 has been recorded in the notifications of measles; the largest rises during the weeks were Yorkshire West Riding 772, Lancashire 242, Gloucestershire 224, and Nottinghamshire 95. A small rise in the incidence of whooping-cough occurred in most areas; the largest increase was in Yorkshire West Riding 58. The decline in the incidence of scarlet fever was slightly greater in the northern section of the country than in the southern. The largest changes in the notifications of diphtheria were decreases in London 9 and Yorkshire West Riding 8, and an increase of 9 in the south-eastern counties.

An outbreak of dysentery affecting 16 persons was notified from Cheshire, New Wirral U.D. Other large returns of dysentery were Lancashire 20 (Oldham C.B. 11, Liverpool C.B. 7) and London 21 (Poplar 9, St. Pancras 9). The largest returns of acute poliomyelitis were Yorkshire West Riding 3, Surrey 3, Lancashire 2, and London 2; no administrative area reported multiple cases.

In Scotland the number of notifications increased for acute primary pneumonia 74, whooping-cough 91, measles 20, and diphtheria 15. There were decreases in the incidence of scarlet fever 15 and dysentery 13. The rise in the incidence of pneumonia was common to all areas. Notifications of diphtheria in Glasgow rose from 9 to 24.

In Eire there was a decrease of 26 in the notifications of measles. This was due to the experience of Laoighis, Athy No. 2 R.D., where an outbreak in the preceding week resulted in 32 notifications, but no case was reported during the week under review.

In Northern Ireland the apparent large increase of 91 in the notifications of measles was due to the fact that this disease has been made notifiable in all areas for the first time.

Week Ending January 15

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 989, whooping-cough 2,825, diphtheria 92, measles 10,922, acute pneumonia 1,184, cerebrospinal fever 28, acute poliomyelitis 34, dysentery 70, paratyphoid 4, and typhoid 5. In the great towns 40 deaths were attributed to influenza.

Medical News

Medical Films

The first two films of a series depicting gynaecological operations have recently been completed. They were photographed by Mr. Stanley Schofield at the Middlesex Hospital, the surgeon being Mr. F. W. Roques. The films, which are in colour, are intended for showing at the end of a lecture to students, and there is no spoken commentary but a number of explanatory subtitles. The full title of the first film, which runs for 18 minutes, is "Subtotal Hysterectomy for Multiple Fibromyomata in a Nullipara aged 43 Years". All the stages of the operation are clearly shown, from the placing of the patient on the operating table to the dispatching of the specimen to the pathological laboratory. The second film is entitled "An Operation for Proctocentesis." It also runs for 18 minutes; the operative technique is based on that described in Berkeley and Bonney's textbook on gynaecological surgery. Information about the distribution of these films can be obtained from their producer, Stanley Schofield, F.R.P.S., 4, Norwood Drive, North Harrow, Middlesex.

Sir Henry Dale on Research

Sir Henry Dale, O.M., F.R.S., recommended doing research part-time when he addressed the Royal Medical Society of Edinburgh on Jan. 21. Coming regularly into living contact with patients helped the part-time research worker to keep his feet on the ground, he said, and might give him a definite advantage over the man who gave all his time to research. It had its moment of exhilaration, but the characteristic of research work was drudgery. There was nothing more discouraging than to see after months, or even years, of toil a beautiful hypothesis slain by an ugly fact. The whole-time research worker had the constant fear that the fount of ideas would dry up as his youth declined, that he would have nothing to show for years of work. Under such conditions many a man had looked with envy on his colleague whose research was a side-line.

French Award

The French Government has conferred the Médaille de la Reconnaissance Française on the following: Mr. Albert Davis, Mr. Gavin Livingstone, Mr. T. M. Tyrrell, Mr. A. D. Wright, and Mr. H. W. S. Wright.

Pharmaceutical Society

The Pharmaceutical Society has appointed Mr. F. W. Adams, deputy secretary, to be secretary with Mr. H. N. Linstead, M.P., to enable the latter to carry on with his public work. Mr. Adams will also be Registrar in succession to Mr. Linstead.

Harveian Society of London

The Buckston Browne Prize for 1948 has been awarded to Dr. V. C. Medvei, M.R.C.P., for his essay on "The Mental and Physical Effects of Pain."

Prospective Parliamentary Candidate

Dr. William James O'Donovan has been adopted as prospective Conservative candidate for Fulham West. He was M.P. for Mile End from 1931 to 1935. Fulham West is at present represented by Dr. Edith Summerskill.

British Schools Exploring Society

Applications are invited for the posts of an honorary physician and an honorary surgeon for the Northern Norway Expedition leaving on Aug. 3 and returning about Sept. 14. The entire cost to each member will be £110 plus about £10 10s. for personal equipment. Applicants should apply as soon as possible to the honorary secretary, White Barn, Old Oxted, Surrey, if possible suggesting a day they could come to London for an interview.

Leverhulme Research Fellowships

Applications are invited for Fellowships and Grants in aid of research, which are intended for senior workers who are prevented by routine duties or pressure of other work from carrying out research. They are limited to British-born subjects normally resident in the United Kingdom, but in exceptional circumstances the trustees may waive the condition as to residence. The trustees are also prepared to consider applications from groups of workers engaged upon co-operative programmes of research, particularly from those engaged upon long-distance programmes or in institutions in which the normal facilities for research have been curtailed by the war. The duration of the awards will not normally extend over more than two years or less than three months, and the amount will depend on the nature of the research and the circumstances of the applicant. Forms of application may be obtained from the secretary, Dr. L. Haden Guest, M.C., M.P., Leverhulme Research Fellowships, 7, Bedford Row, London, W.C.1. Applications must be received by March 1; awards will be announced in July and will date from Sept. 1.

Willis

Dr. William Henry Lewis, of Llansantffraid, who was High Sheriff of Montgomeryshire in 1935, left £25,562. Mr. Percival Pasley Cole, late surgeon to the Dreadnought Hospital, Greenwich, left £16,104. Dr. Robert Nimmons, of Pelton, Durham, left £12,115; Dr. Herbert Charles Mooney, of Dublin, £6,832; and Dr. Noel William Berry, of Alverstoke, Hants, £26,664.

COMING EVENTS**Association of Clinical Pathologists**

A scientific meeting of the Association of Clinical Pathologists began at Westminster Hospital, London, S.W., on Thursday, Jan. 27 and will be continued to-day (Friday, Jan. 28) and to-morrow (Saturday, Jan. 29) at 9.30 a.m.

Contraceptive Technique

A lecture and demonstration (on living models) on contraceptive technique will be given by Dr. Marie C. Stopes and Dr. Beddow Bayly at the Mothers' Clinic, 108, Whitfield Street, Tottenham Court Road, London, W., on Thursday, Feb. 3, at 2.30 p.m. Tickets must be obtained in advance, as space is limited.

British Tuberculosis Association

A meeting of the British Tuberculosis Association will be held at the Hospital for Sick Children, Great Ormond Street, London, W.C., on Saturday, Feb. 5, at 10 a.m. Members are reminded that the annual conference of the association will be held at Trinity College, Cambridge, on April 6, 7, and 8.

Banting Memorial Lecture

As briefly announced in this column in the *Journal* of Jan. 22, Professor John Beattie, Bernhard Baron Research Professor at the Royal College of Surgeons of England, will deliver the Banting Memorial Lecture on "Metabolic Disintegrations" at the University of Toronto on Monday, Feb. 14. The lecture is being delivered at the invitation of the Dean of the Medical Faculty of the University.

Scientific Treatment of Delinquency

A course of six lectures on "Difficult and Delinquent Personalities: The Freudian Approach" will be given by Miss Barbara Low at the Institute of Scientific Treatment of Delinquency, 8, Bourdon Street, Davies Street, London, W., on Tuesdays, Feb. 22, March 8, 15, 22, and 29, and April 5, at 6 p.m. The fee for the course, which has been specially arranged for teachers, parents, and welfare workers, is 7s. 6d. Enrolment forms may be obtained from the Education Secretary of the Institute at the address above.

Refresher Course for G.P.s

The Edinburgh Postgraduate Board for Medicine is arranging a 14 days' refresher course for general practitioners, starting on May 9. The course will include instruction suitable for general practitioners in aspects of medicine, surgery, and the ancillary services. Emphasis will be laid on advances in therapeutics. Twenty hours are devoted to lecture-demonstrations and 50 hours to clinical demonstrations and ward visits. Fee for graduates not claiming expenses from Government sources: 10 guineas. Application should be made to the Director of Studies, Edinburgh Postgraduate Board for Medicine, University New Buildings, Edinburgh.

SOCIETIES AND LECTURES**Monday**

UNIVERSITY COLLEGE LONDON.—At Physiology Theatre, Gower Street, London, W.C., Jan. 31, 4.45 p.m. "The Ultracentrifuge and Electrophoresis Apparatus in Protein Research," by Dr. P. Johnson, Ph.D.

Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Feb. 1, 5 p.m. "Lupus Erythematosus," by Dr. W. N. Goldsmith.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Feb. 1, 11 a.m. "Lymphogranuloma Inguinale and Granuloma Venereum," by Dr. W. N. Mascall.

UNIVERSITY COLLEGE LONDON.—At Physiology Theatre, Gower Street, London, W.C., Feb. 1, 5.15 p.m. "Digestion and Metabolism," by Dr. E. A. Underwood.

Wednesday

EDINBURGH CLINICAL CLUB.—At Edinburgh Royal Infirmary (Ward 8), Feb. 2, 4 p.m. "Peripheral Vascular Disturbances," by Professor J. R. Learmonth.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Feb. 2, 11 a.m. "Condylomata Acuminata," by Dr. A. H. Harkness.

ROYAL MICROSCOPICAL SOCIETY.—At B.M.A. House, Tavistock Square, London, W.C.—Feb. 2, 6 p.m. Biological Section meeting. "Some Biological Aspects of Experimental Schistosomiasis," by Mr. O. D. Standen, M.Sc.

SOCIETY OF CHEMICAL INDUSTRY: FOOD GROUP.—At Portsmouth Municipal College, Feb. 2, 7 p.m. Joint meeting with Portsmouth and District Chemical Society. "Food Science in Evolution." Address by Dr. L. H. Lampitt.

SOCIETY OF PUBLIC ANALYSTS.—In Hall of Royal Society of Tropical Medicine and Hygiene, 26, Portland Place, London, W., Feb. 2, 7 p.m. Papers to be presented and discussed.

UNIVERSITY COLLEGE LONDON.—At Anatomy Theatre, Gower Street, London, W.C., Feb. 2, 5 p.m. "Speech and Society," by Mr. David Abercrombie.

Thursday

FACULTY OF HOMOEOPATHY.—At Royal London Homoeopathic Hospital, Great Ormond Street, London, W.C., Feb. 3, 5 p.m. "Homoeopathy and the Psychosomatic Approach." Address by Dr. F. H. Bodman.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Feb. 3, 5 p.m. "Drug Eruption," by G. B. Mitchell-Heggs.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., Feb. 3, 11 a.m. "Residual (non-gonococcal) Urethritis (Post-gonorrhoeal)," by Dr. A. H. Harkness.

LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At London Jewish Hospital, Stepney Green, E., Feb. 3, 3 p.m. Clinical demonstration.

ROYAL PHOTOGRAPHIC SOCIETY: MEDICAL GROUP.—16, Prince's Gate, London, S.W., Feb. 3, 7 p.m. "Forensic Photography," by Detective Inspector P. G. Law.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—At Large Lecture Theatre, Feb. 3, 4.30 p.m. Lecture-demonstration: "Psychiatry."

Friday

LONDON CHEST HOSPITAL, Victoria Park, E.—Feb. 4, 5 p.m. "Differential Diagnosis of Carcinoma of the Lung," by Dr. E. H. Hudson.

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh, Feb. 4, 8 p.m. "The Surgery of Cholelithiasis and the Complications of Operative Treatment," by Mr. Rodney Maingot.

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHARMACOLOGY.—At Physiology Theatre, Gower Street, London, W.C., Feb. 4, 5.15 p.m. "Natural and Synthetic Analgesics," by Dr. G. Bergel, Ph.D.

For Relief of Sacro-iliac Pain prescribe SPENCER

Shewn here is a Spencer Sacro-iliac Support and Breast Support designed especially for this patient. A pelvic binder of non-elastic webbing (see inset) encircles the pelvis inside the support to exercise the degree of control required.

The reason why Spencer Supports are therapeutically effective is: Each Spencer Support is *individually designed, cut and made* at our Banbury Manufactory—after a description of the patient's body and posture has been recorded and detailed measurements taken. The doctor's instructions are carefully followed.

This assures the doctor that each patient will receive the proper design to aid his treatment; that the support will fit with precision and comfort.

MULTIS TERRIBILIS CAVETO MULTOS (AUSONIUS)

those that are a cause of fear to many should themselves avoid crowds. In Rome, do as the Romans do. But in modern times crowds are as difficult to avoid as the virus of the common cold. 'Endrine' nasal compound provides a simple method of treating coryza and catarrh. It contains ephedrine which shrinks the engorged mucosa, whilst the oily base brings soothing relief to the inflamed membranes. Free breathing becomes possible and roplet infection is prevented.

ENDRINE Nasal Compound

Formula: ephedrine
0.75% w/w; menthol
0.5% w/w; camphor
0.5% w/w; eucalyptol
0.5% w/w; oleum
ricini 0.35% w/w; light
liq. paraffin q.s. to 100.

Ortho-Gynol

VAGINAL JELLY

for effective conception control

- EFFECTIVE**... by Huhner test and clinical studies; rapid spreading and low surface-tension ensure instantaneous action of the spermicide.
- TOLERABLE**... by biopsy and clinical observation after prolonged use. Entirely free from toxic or irritant materials.
- BUFFERED**... The spermicidal action is independent of the acidity—which is therefore buffered at pH.4.5. Regular use tends to assist maintenance of the healthy vaginal flora.
- STABLE**..... In any climatic extremes.

An elegant scientific preparation affording the logical prescription when contraception is indicated. For use alone by means of measured-dose applicator or in conjunction with the Ortho Vaginal Diaphragm.

Active ingredients:
Ricinoleic acid 0.75% w.w., boric acid 3.0% w.w. and oxyquinoline sulphate 0.025% w.w.

The Association of Psychiatric Social Workers publishes an interesting journal on the work done by its members entitled *The British Journal of Psychiatric Work*. It is obtainable at 3s. 6d. (postage 4d.) from that Association, 1, Park Crescent, London, W.1. The second issue, which has recently been published, contains articles on such topics as "Child Guidance in the Nursery School," "The Preparation of Parents for Treatment in a Child Guidance Clinic," and an investigation into the psychology of pregnancy and lactation.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Graduated Exercise in Pulmonary Tuberculosis

Q.—What is the present view of the part played by graduated exercise in the treatment of pulmonary tuberculosis—is it actively beneficial in promoting the healing of a lung lesion, or is it to be regarded in the more passive sense as a gradual relaxation of the conditions of complete rest as the patient's clinical condition improves?

A.—Graduated exercise under careful control is beneficial in both the ways mentioned by the questioner. It increases physical fitness and bridges the gap between the rest cure and a return to normal activity. Controlled exercise can also be used to test the activity of a doubtful lesion; this is particularly valuable in the case of minimal, symptomless lesions discovered by routine radiography. As the ultimate healing of tuberculosis takes many years, it is obviously impossible to keep the patient at complete rest until this is achieved. A course of graduated exercises is prescribed only after an adequate period of rest has controlled the toxæmia and rendered the disease non-progressive. Many years ago Kingston Fowler remarked that treatment by rest alone tended to convert sick workers into healthy loafers. A course of graduated exercise avoids this danger and is a valuable adjunct to the rehabilitation of many tuberculous patients.

Breathing Exercises in Pulmonary Tuberculosis

Q.—Are gentle 'respiratory exercises of benefit in cases of pulmonary tuberculosis in which only a small area of infection remains in the lungs? Would exercises to correct posture be advisable in a patient who has been in bed for over a year and who has slight infiltrations remaining in the upper lobe of the left lung?

A.—As rest is the basis of the treatment of pulmonary tuberculosis, respiratory exercises should not be used in this condition. Postural correction exercises are employed with great benefit after a thoracoplasty and might be indicated in the case here described, but all forms of breathing exercises designed to increase lung movement should be avoided.

Liver Extracts

Q.—I notice in American literature that liver extract is measured in units per ml. Can you define the unit?

A.—The United States Pharmacopoeia Anti-Anaemia Preparations Advisory Board assesses liver extracts and awards the various commercial preparations a "unit value per ml." As, to date, the only method of assessing liver extracts is by clinical test on classical cases of Addisonian anaemia in relapse, "unit" cannot be a precise term, as patients may vary in their response to potent extracts. Further, "a satisfactory response" has to be defined. Formulae for judging a "satisfactory response" are discussed by Della Vida and Dyke (*Lancet*, 1942, 2, 275), who stress the importance of assessing the gain in red cells in addition to the reticulocyte response.

The American (U.S.P.) "unit" represents the minimal amount of the therapeutic agent which, when given daily in an uncomplicated case of pernicious anaemia, has produced a "satisfactory" or average reticulocyte response and subsequent relief of anaemia and symptoms. The Canadian unit is defined as one-seventh of the weekly dose of extract required to produce a satisfactory response. Emery and Hurren (*British Medical Journal*, 1945, 1, 75) prefer an arbitrary "unit" system to the labelling of extracts as "derived from so much raw liver" or "equivalent to so much oral liver"; they also suggest a "purification index." At present, however, no method exists for the comparison of British-made extracts by a "unit" system; the U.S.P. "unit" can be criticized in that it is based on figures submitted to an advisory board by manufacturers.

and the "unit" has no reference to a standard preparation. Further, because of recognized difficulties in securing numerous clinical tests, the "unit" perforce indicates only the particular amount of material which has been approved, and this is not always the minimum amount. Therefore U.S.P. "units" of different preparations are not necessarily strictly comparable in potency.

Cold Permanent Waving

Q.—It would be interesting to know the latest opinion on the safety of the "cold" permanent wave outfits now on sale. Have any further investigations been made since the article by Cotter, and with what results?

A.—Further investigations have been carried out since the article by Dr. Lawrence Cotter (*J. Amer. med. Ass.*, 1946, 131, 502). It is true that many people have obtained good results with the so-called "cold perm" method. Many have never had any injury to their hair, scalp, or health. On the other hand, the writer has seen several patients who had had the "cold perm" process given to their hair by skilled assistants, in establishments of high repute, yet had suffered damage to both their hair and scalp; also, in some cases, to the neck and face. Apparently the occasional ill effects are due to the employment of solutions of thioglycollic acid in too high a concentration or for too long. In this country it has been consistently maintained that this acid should not be used, but hydrogen sulphite only, as the reducing agent. The method was first discovered in Britain, but could not be tried out during the war. The Americans went ahead and popularized the process. All writers agree that the operators are the chief sufferers, their fingers, nails, and general health being sometimes affected, as described by Cotter. For further details of the process, and the precautions to be taken, the articles by Goldman *et al.* (*J. Amer. med. Ass.*, 1948, 137, 354) and by McNally and Scull (*Arch. Derm. Syph. Chicago*, 1948, 57, 275) should be consulted.

Schick Test in Young Children

Q.—After two or more injections, young children often resent the Schick test. Is there any need to test the second forearm with the Schick control in children under 5, and, if so, why?

A.—The Schick test is used for two main purposes: (a) to test susceptibility to diphtheria, and (b) to test the efficiency of artificial immunization. In either case non-specific reactions or pseudo-reactions with the Schick control material rarely occur in children under 5 years of age, and therefore the control test may ordinarily be omitted in this age group. However, Bousfield *et al.* (*Med. Off.*, 1948, 80, 145) in their trials with Holt's P.T.A.P. have found that there is a tendency for some young children (under 2 years of age) to give pseudo-reactions with a post-inoculation Schick test. It would therefore seem advisable to use the control test on a sample of children whenever the efficiency of any new diphtheria prophylactic is being investigated.

Repeated Stillbirths

Q.—A 43-year-old woman is 30 weeks advanced in her seventh pregnancy. The first two were normal, but the next four ended in stillbirths. Wassermann and Kahn reactions were repeatedly negative; labour was always easy, and there was no albuminuria, hypertension, or glycosuria. The smallest baby weighed over 5 lb. (2,268 g.), though two of the stillbirths were premature. The present pregnancy appears to be normal: Wassermann reaction still negative, blood pressure and uric acid normal. The patient's blood is Rh-positive, Group A. What further investigations should be carried out, and what treatment is indicated?

A.—The history suggests that the foetuses died before rather than during labour, and it would be helpful to know whether there is evidence to support this, and whether post-mortem examinations were carried out to exclude malformation and other obvious causes of death. Other possibilities to exclude are ABO group iso-immunization and "occult" diabetes. A glucose-tolerance test would be worth while. If the cause of the stillbirths still remains obscure, it is too late in this pregnancy for empirical medical treatment, and the chief hope lies in terminating the pregnancy prematurely. This should be done about the 37th week, provided the foetus is then of

reasonable size. Possible methods, depending on the circumstances at the time, are surgical induction of labour or caesarean section under local analgesia.

Testosterone in Progressive Muscular Atrophy

Q.—It has been suggested that a case of progressive muscular atrophy might be treated with methyl testosterone. Have you any information regarding this or any other treatment?

A.—Progressive muscular atrophy arises from degeneration of cells in the spinal cord. The muscular atrophy depends entirely on the nervous degeneration, so that any direct effect that methyl testosterone might have on the muscle would be of no avail. It is most unlikely upon *a priori* grounds that this form of treatment would affect muscular disease. Methyl testosterone was suggested for this condition because of its anabolic action in eunuchoidism and hypopituitarism, producing a retention of nitrogen with positive balance and an increase in muscular development and strength. It would have no effect on the fundamental lesion in progressive muscular atrophy, or on the progress of the condition.

Quinine in Breast Milk

Q.—If a nursing mother living in a malarious country takes 2 gr. of quinine sulphate or bisulphate daily for several months, can this have any harmful effect on the infant? In the case I have in mind the child, who is now grown up, seems to be mentally retarded, and I wonder if there can be any connexion between this and the quinine taken by the mother.

A.—Quinine and its degradation products are excreted in breast milk only in very small amounts. Quinine has a toxic action on certain nerve cells connected with hearing, and possibly on the ganglion cells of the retina. Such an action is always acute in character, leading to deafness or toxic amblyopia. There is no evidence that the drug has any action in causing dullness or retardation, and in the present instance the amount of quinine absorbed by the child must have been infinitesimal. Incidentally, the dose of 2 gr. (0.13 g.) of quinine salts daily taken by the mother is totally inadequate for any purpose whatsoever. A daily dose of 5 gr. (0.32 g.) is the minimum which can be considered to act as a malaria suppressive, and even this is followed by many failures.

NOTES AND COMMENTS

Bleeding Gums.—Mr. C. N. JEFFRIES, L.D.S. (Birmingham), writes: With reference to your answer to the question about bleeding gums ("Any Questions?" Jan. 1, p. 41) I must confess I was disappointed with the information given. It is, of course, impossible in the short space available to give a comprehensive reply, but I would like to suggest the following points for inclusion to any medical man who is interested in this problem: (1) For healthy persons bleeding gums are very common, perhaps 90% of all patients from the age of 15 upwards. (2) The treatment is primarily the responsibility of the dental surgeon. (3) The aetiology is very well given in Fish's *Surgical Pathology of the Mouth* (1948, chap. 12). (4) Bleeding gums is the first stage in the process commonly known as "pyorrhoea." As such it needs early recognition and skilled care and attention. (5) Treatment consists in making the mouth susceptible to oral hygiene by scaling the teeth, extracting unsavable carious teeth, filling other carious teeth, etc. (6) Follow-up treatment consists in teaching the patient adequate methods of oral hygiene, the prime aim being to give the gums sufficient friction every day to cause them to be covered with an adequate layer of keratinized epithelium.

The teaching and institution of oral hygiene is a long, tedious, and arduous process, taking sometimes many months. Surgical treatment of the teeth and gums is sometimes needed before the mouth is properly prepared for oral hygiene. The blood dyscrasias and vitamin deficiencies mentioned in your answer hardly apply to the healthy person.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JANUARY 29 1949

THE SECRETARY REPORTS

THE APPLICATION OF SPENS

It is now possible to map out some events immediately ahead. Most of the reports on general-practitioner remuneration in the selected areas have now come in. The Remuneration Subcommittee of the General Medical Services Committee will meet on Feb. 4 to consider these reports together with all other available information, and to draft a report to be made to the General Medical Services Committee at a special meeting on Feb. 9. Upon this committee falls the responsibility of making recommendations to a special conference of Local Medical Committees to be held on March 3. A Special Representative Meeting to consider remuneration in the new Service will be held on March 29. On the following day, March 30, another Special Representative Meeting will be held to consider a report from the Council on the constitution of the Association. This second meeting is in response to a request made at the Annual Representative Meeting last year.

General Practitioner Remuneration

To understand the relationship of the General Practitioner Spens to remuneration it is necessary to recall where that committee stood on the subject of betterment. The Spens Committee reported in terms of net incomes and pre-war money values. It also recommended that in translating its recommendations into terms of post-war money, regard should be had not only to estimates of the change in the value of money, but to the increases which have in fact taken place since 1939 in incomes in other professions. The Government laid down though the representatives of the profession did not accept the figure of 20% as the betterment figure in relation to the net capitation fee. It laid down too, a figure of 55% in relation to the expenses portion of the capitation fee. Combining these two figures, a betterment factor of 24% of the gross capitation fee was applied.

In answering the question whether the Spens recommendations are being applied to-day, one must use a betterment factor of some kind. For example, it might prove that the Spens recommendations are being applied to particular ranges of income on the assumption of a 20% betterment factor. But if the betterment factor applied is too small, and a more appropriate figure is, say, 50%, then the Spens recommendations might no longer be observed in relation to that range. To put it in another way, the betterment factor must be a satisfactory one before the question whether Spens is being applied can be faithfully answered. This separates the betterment factor from other issues as one to be examined separately. Indeed it is desirable to settle the betterment issue in advance of any attempt to decide whether Spens is being applied. This is the order in which the issues are being taken. The size of the mileage fund was taken first as a matter of urgency. By the time these words appear representations of consultants and general practitioners will have been made to the Ministry (on Jan. 26) to raise the betterment issue as a distinct question concerning both general practitioners and specialists alike. The outcome of these representations should be known before the Conference of Local Medical Committees and the Special Representative Meeting decide their policy and the action to be taken.

Betterment

The raw material for the betterment discussion includes the expert's report on middle-class incomes, an account of which

was published in this column a week ago. When this same expert first examined the problem at our request in 1946 he compared the year 1945 with 1938. Taking 1938 as 100, he expressed the view that the corresponding figure for the middle-class budget in 1945 was 145-150. He has now re-examined the position as between 1948 and 1938 and still taking 1938 as 100, he now gives the figure as 185. Put briefly, when the right figure was, say, 150, the Government laid down a figure of 120. To-day the right figure is 185.

The Three Main Issues

It was clear from the discussion at the special meeting of the General Medical Services Committee on Jan. 19 that in the general view there were three main issues on general practitioner remuneration. They are betterment, the burden of work, and the small list. On the question of the burden of work the majority view was that it was extremely heavy, some doubting whether it was possible for the practitioner with the full list to sustain the burden without impairing his health or his efficiency. On the other hand one well-known practitioner gave it as his experience in his own practice that there had been no substantial increase of work. It was plain that the two questions of the burden of work and the size of the permitted maximum were really different aspects of the same question. We cannot sustain the argument that the burden of work is so great as to make it impossible to look after 4,000 persons without in effect inviting a reduction of the permitted maximum. This issue must be faced.

The problem of securing sufficient income for the practitioner with a list of average size or less is of no less importance. How could it be obtained? It might be obtained by making a fixed annual payment in respect of expenses to every general practitioner working in the Service, regardless of the number of persons on his list. This has some obvious disadvantages, not the least of which is that it might be regarded as the basic salary in another form. But if deliberately regarded as an expenses allowance it might escape this stigma. Another is the method of a higher capitation fee for, say, the first 1,000 persons on the list.

Terms of Service for Consultants

In response to a request from Sir Lionel Whitby, chairman of the Joint Committee for Consultants, Sir William Douglas, the Permanent Secretary of the Ministry of Health has clarified the position as to the procedure to follow the confidential discussions now proceeding. In these discussions the Joint Committee is not committing consultants and specialists but informing the Ministry what in their view is likely to be acceptable or more acceptable to the profession. These discussions completed, the Ministry proposes to issue a paper revised in the light of the discussions on which a sounding of the profession's views can be obtained. The Ministry's paper will be published and submitted to the constituent bodies of the Joint Committee for their observations. To allow time for this the present interim arrangements will need to be continued for a further three months.

The Secretary addressed meetings of the profession on current problems in B.M.A. House on Jan. 27 and at St. Albans on Jan. 28. He will address similar meetings at Leeds on Feb. 1, at West Bromwich on Feb. 10, at Luton on Feb. 11, at Grimsby on Feb. 15, at Cardiff on Feb. 23, at Bournemouth on March 1, at Lancaster (Annual Dinner) on March 5, and at Winchester on March 31.

National Health Service

NEGOTIATIONS WITH THE MINISTRY CONDITIONS OF SERVICE

The B.M.A. is continuing to press the Ministry of Health about terms and conditions of service in the National Health Service, and the Ministry has recently made the following decisions:

Training Grants for Assistants

Local medical committees are now dealing with applications from practitioners for permission to employ trainee assistants. In view of the limited number of trainee assistants who will be available each year it has been suggested that further guidance should be issued to local medical committees to assist them in dealing with applications. As a result of discussions which have taken place with the Ministry, the General Medical Services Committee will be considering a draft circular on this matter this week, and the terms of the circular will be published in the *Journal* as soon as possible.

Maternity Medical Services

Forms E.C.24 and 24A.—The Ministry has agreed that, provided a practitioner carries out the statutory examinations, failing to do them within the period defined for reasons outside his control would not involve a loss of fees. The Ministry has undertaken to make the position clear to executive councils.

The Ministry agrees that executive councils should provide itemized accounts showing the names of patients in respect of whom maternity fees are paid. While there is no evidence to suggest that this is not being generally done, it is suggested that any practitioner who requires this itemized information and is so far been unable to obtain it should take the matter up first with his local executive council, referring to the Ministry's general agreement set out above.

Forms of Application for Maternity Benefit.—The Ministry of National Insurance has agreed that requests by doctors for supplies of these forms will be met by local offices of the Ministry.

Consultations on Regulations and Instructions Relating to General Medical Services

The Ministry has accepted the general principle that the Association should be consulted on points of major principle involving regulations.

Prescribing and Dispensing

The Ministry has agreed to set up a small medical committee representative of the Ministry and the Association to examine the schedule of appliances which may be prescribed by general practitioners.

Missing Information on Forms E.C.1

The Ministry has agreed that information missing from Forms E.C.1 should be obtained from the patient rather than from the doctor.

The Ministry is now considering the following points and the B.M.A. is awaiting a reply:

Miscarriages

The Association strongly holds the view that miscarriages and other obstetric emergencies should not form part of the normal terms of service of a general practitioner and that a special fee should be admissible for such emergencies.

Telephone Charges

The Association has urged that all telephone calls, other than local, in connexion with the admission of patients to hospital, etc., should be reversed, or the practitioner reimbursed in some other way.

Specialization

The Association has represented that a number of specialist services often undertaken by general practitioners should come outside the terms of service and that a special fee should be admissible. It is urging that some such arrangements as existed

under the National Health Insurance should be continued in the new Service.

The Ministry has not conceded the following points put forward by the Association:

(1) That there should be special payment for general practitioners called out to render emergency treatment for haemorrhage following dental extractions.

(2) That overseas visitors should not be entitled without payment to the benefits of the National Health Service.

(3) That all official communications sent by general practitioners to executive councils, etc., should be franked.

The General Medical Services Committee will shortly consider what further action should be taken on these points.

CONFERENCE OF REPRESENTATIVES OF SCOTTISH LOCAL MEDICAL COMMITTEES

With the authority of the General Medical Services Committee a Conference of Representatives of Scottish Local Medical Committees will be held in Edinburgh on Feb. 10 under the chairmanship of Dr. W. M. Knox (Glasgow). The object of the Conference is to consider (1) the constitution and method of appointment of permanent local medical committees in Scotland and the desirability of preparing a model scheme; (2) the method of central representation of Scottish local medical committees; (3) any other relevant questions.

The Conference will be composed of (a) Representatives from Scottish local medical committees appointed as follows:

5 from Glasgow Local Medical Committee,
4 from Edinburgh Local Medical Committee,
4 from Lanarkshire Local Medical Committee,
2 from the remaining local medical committees; with provision for a deputy in each case.

(b) Members of the General Medical Services Subcommittee (Scotland), who will not be entitled to vote unless they are attending the Conference as representatives or acting deputy representatives of a local medical committee. The Chairman of the General Medical Services Committee hopes to be present.

NEGOTIATING MACHINERY

Now that the Negotiating Committee has gone out of existence, discussions with the Ministry are being undertaken

(a) on behalf of consultants and specialists by the newly formed Joint Committee of Representatives of the Royal Colleges, the Royal Scottish Corporations, and the Consultants and Specialists Committee of the British Medical Association;

(b) on behalf of general practitioners by the General Medical Service Committee;

(c) on behalf of public health medical officers by the Public Health Committee of the British Medical Association in collaboration with the Society of Medical Officers of Health.

In the field of ophthalmology discussions which have been conducted over a long period by the Joint Committee of the Faculty of Ophthalmologists and the Ophthalmic Group Committee of the Association are being continued by that Committee.

CENTRAL HEALTH SERVICES COUNCIL COMMITTEE ON HEALTH CENTRES

The Central Health Services Council has appointed a committee, which held its first meeting on Jan. 18, to consider and make recommendations on the lines along which health centres should be developed under Section 21 of the National Health Service Act. The members are: Mr. F. Messer, M.P. (chairman); Mr. F. J. Ballard; Dr. G. O. Barber; Dr. A. Beauchamp; Dr. D. Cameron; Sir Ernest Rock Carling; Sir W. Allen Daley; Dr. L. Findlay; Capt. S. H. Hampson; Miss M. E. Hollingworth, S.R.N.; Mr. R. H. Henriksen, M.P.S.; Dr. R. D. Lawrence; Professor J. M. Mackintosh; Professor R. H. Parry; Dr. A. Talbot Rogers; Miss Blanche Shenton, S.R.N.; Mrs. Dorothy Thurtle. Secretary: Miss E. G. Long, of the Ministry of Health.

PROPOSALS FOR REMUNERATION OF WHOLE-TIME PUBLIC HEALTH MEDICAL OFFICERS

In the following proposals the salary scales—which were originally formulated in terms of 1939 values—include a "betterment" factor of 20%, as in the Ministry's proposals relating to general practitioners' remuneration. This percentage has not yet been accepted and is subject to further negotiations.

I. *Medical Officers in Departments.*—(a) These are officers who, although without responsibility for the work of other medical officers, have had at the time of appointment at least three years' experience in the practice of their profession after obtaining a registrable qualification. (b) Salary: £960 per annum, rising to £1,680 by annual increments of £60.

II. *Senior Medical Officers.*—(a) These are medical officers not being Medical Officers of Health) who are in charge of services or departments (for example, port health, school health, mental health, maternity and child welfare, or any other similar service or combination thereof), and who are engaged solely or mainly on such duties. (b) Salary:

Population Not Exceeding	Minimum	Annual Increments	Maximum
100,000	£ 1,680	£ 120	£ 2,160
200,000	1,800	"	2,280
300,000	1,920	"	2,400
Exceeding 750,000 ..	2,040	"	2,520

(c) Where a medical officer in Section I is in charge of a service(s) or department(s) but is not solely or mainly engaged on such duties, he should be remunerated on the scale of Section I with an addition of £100 per annum. Such an arrangement would obtain in a local authority with a population so small as not to justify the appointment of a medical officer solely or mainly engaged on the duties of a senior medical officer.

III. *Deputy Medical Officers of Health.*—(a) These are medical officers employed primarily as administrative Deputy Medical Officers of Health. (b) A medical officer appointed in this grade shall receive a salary scale not less than the appropriate salary scale for a Senior Medical Officer in Section II plus £100.

IV. *Acting Deputy Medical Officers of Health.*—In areas where no Deputy Medical Officer of Health as defined in Section III is necessary, a Senior or Departmental Medical Officer appointed to act as and when necessary as deputy in the absence of the Medical Officer of Health shall receive an addition to his scale salary of not less than £100 per annum.

V. *Medical Officers of Health.*—(a) Salary: For Medical Officers of Health of all classes of local authority:

Population Not Exceeding	Minimum	Annual Increments	Maximum
100,000	£ 1,920	£ 120	£ 2,400
200,000	2,160	"	2,640
300,000	2,400	"	2,880
500,000	2,640	"	3,120
750,000	2,880	"	3,360
Exceeding 750,000 ..	3,120	"	3,600

(b) The salary of a practitioner appointed as a part-time Medical Officer of Health shall be $\frac{x}{11}$ of the appropriate salary, according to population for a whole-time Medical Officer of Health, plus $\frac{1}{4}$ of $\frac{x}{11}$ or $\frac{1}{4}$ of $\frac{11-x}{11}$ whichever is the less, where x represents the number of half-days per week, or their equivalent, devoted to the appointment.

VI. *Combined Appointments—Medical Officers of Health.*—(a) Where a medical officer acts as Medical Officer of Health to more than one authority he shall receive a salary scale not less than £120 above the appropriate salary scale in Section V (a) indicated by the total population of the combined districts for which he is Medical Officer of Health. (b) Paragraph (b) of Section V shall apply where a combined appointment is part-time. (c) In Scotland, where a County Medical Officer of Health is also School Medical Officer for the County

and for one or more large burghs, the population of which is not included in the population of the administrative county, he shall receive a salary scale not less than the appropriate salary scale in Section V (a) above indicated by the total population of the administrative county and large burgh(s).

VII. *Divisional or Area Medical Officers.*—These are medical officers appointed by local health authorities for divisional administration of the health services (including the school medical service). They fall into two classes: (a) *Divisional Medical Officers acting also as County District Medical Officers of Health:* The salary scale shall be the appropriate scale in Section V according to population of the division or area, or population of the county district(s) for which he is acting as Medical Officer of Health, whichever is the greater. (b) *Divisional Medical Officers not also acting as County District Medical Officers of Health:* The salary scale shall be the appropriate scale in Section II above, according to population of the division or area.

VIII. *Specialists.*—Where a whole-time medical officer in any of the above sections is employed partly by a regional hospital board and partly by a local authority his total remuneration shall be the whole-time remuneration recognized by the regional hospital board for the type of work undertaken for them, or the salary scale appropriate to his position in the local authority, whichever is the higher.

IX. *Special Awards.*—A proportion of medical officers of outstanding professional eminence in the public health service should receive as a special award payment in excess of the remuneration provided for in the scales.

X. *General Conditions.*—Many general conditions of service are also the subject of proposals.

MR. MESSER ASKED TO RESIGN

The following resolution was passed by the Middlesex Local Medical Committee at a recent meeting:

That Mr. Messer be asked to resign from the important positions held by him on the Central Health Services Council and the North-western Metropolitan Regional Hospital Board on the grounds of his unsuitability to continue in these posts, and that this resolution be sent to the General Medical Services Committee.

PAYMENT FOR TEMPORARY RESIDENTS

The Ministry of Health states that the distribution scheme which governs payments to general practitioners for temporary residents—anaesthetics and emergency treatment—will appear very shortly. The Ministry intends the model scheme to be available in time for executive councils to make their own schemes by the end of March.

WELSH COMMITTEE

The Welsh Committee has met and considered the views of the Branches and Divisions in Wales on the proposed new constitution of the Welsh Committee. The committee will forward a report and recommendation to Council.

MEDICAL PRACTICES ADVISORY BUREAU A BRANCH IN MANCHESTER

Mr. S. Beedle, A.C.I.I., for many years manager of the Northern Branch of the British Medical Bureau, has been appointed officer in charge of the Manchester Regional Office of the British Medical Association. He will also act as Branch Manager of the Medical Practices Advisory Bureau and will maintain an Appointments Information Service to advise doctors seeking openings in the various fields of medical practice, and to introduce partners, assistants, and locums.

Any member of the profession in the North of England is invited to utilize the services of the Manchester Regional Office, and inquiries should be addressed to the Medical Director, Medical Practices Advisory Bureau, 33, Cross Street, Manchester (Telephone: Blackfriars 3925). The service is free of charge to members of the Association; to other medical practitioners charges will be made to recover expenses, and an announcement appears in the advertisement columns on page iii of cover.

REFLECTIONS ON N.H.S.

BY

R. W. COCKSHUT, M.B., Ch.B.

When the Willink White Paper was debated by the Representative Body a great fight developed on the proposals to put the Service under the control of the Minister and to make it available for 100% of the population. Several of us opposed these two things, but it proved impossible to get the support of the G.P.s, while the specialists at that time seemed scarcely interested. Looking back, I am not certain that we were right in opposing. The State and modern medicine were bound to come together. The only alternative to Ministry control was an *ad hoc* body. We have seen in the last three years how impossible it has been effectively to criticize these bodies, and it may be that a Minister, subject to the daily fire of the House of Commons, is preferable. As to the 100%, Dr. Dain never received an answer to his frequent requests for a workable alternative.

But, whatever the rights of the matter, one thing is certain. By agreeing to this course the R.B. took decisions of momentous consequences that even now do not seem to be realized. It is essential to grasp this in order to understand what happened afterwards. From that moment the fight became one not against a State health service but to secure the maximum safeguards to professional freedom within a limited field, and from that moment also the B.M.A. never lost an opportunity of declaring its whole-hearted support for a comprehensive service. There were those who felt then that all was lost, but who on reflection decided that if the Association could secure certain things all might yet be well.

A Threat to Freedom of Medicine

The participation of the State as proposed represented, represents, and always will represent a threat to the freedom of medicine. Was it possible to make arrangements so that we should remain free to defend medicine? This was the 'maximum aim. It is quite impossible to make arrangements at any given time, in such a matter as this, which will ensure perpetual safety. It is possible to arrange that in the continuing contest, over the years, we are not handicapped out of the race. Given an air field and no favour we looked to secure a state of affairs in which, by reason of our demonstrated and continuing strength, we could continue to defend ourselves with success.

There is now a widespread sense of irritation and disillusionment in the profession. Some feel that they have been almost betrayed, at best ill-led. I write this brief account in order that the profession may understand the thoughts which passed through the minds of some of us and in the hope that it may agree that a victory was won within the limited field defined by the R.B. when it agreed to a comprehensive 100% service. If the profession disagreed with this policy, why was no attempt ever made to change it? According to our constitution it was always possible to bring a resolution before the R.B. to reverse it. The fact remained that we declared ourselves wholeheartedly in favour of a national health service. Critics who did not subscribe to this are within their rights, but should not criticize the B.M.A. for adhering to the policy laid down by its democratic machinery and never challenged. The acceptance of the 100% issue made it certain that doctors in some private-practice areas would be driven out of business and forced to move. This "redistribution of doctors by the natural force of a universal capitation fee" became one of the B.M.A.'s strong arguments against direction.

The coming of Labour into office faced us with the prospect of a whole-time salary in local government employ. Mr. Bevan was made aware of the strength of our case, and his proposals surprised everybody and disappointed his friends by departing widely from Labour Party policy. Instead of putting the hospitals and G.P.s under the local authorities, the latter were banished from both these fields. Private practice was not prohibited and private beds in hospital were allowed. To be fair, it must be said that it was to these facts that Mr. Bevan referred when he so frequently talked about the concessions he

had made to the doctors. Mr. Bevan had also seen that free choice in a salaried service was impossible, and therefore he preferred part payment by capitation fee. There were other favourable items.

When it became known that Mr. Bevan might suggest taking over the voluntary hospitals the B.M.A. was advised that there would be a violent public reaction to such an act of confiscation. Plans were made to join the B.M.A. in this reaction and to give maximum support to the voluntary hospital associations in their expected fight.

The plan was published. Within a week it was clear that the owners of the voluntary hospitals were not prepared to make any fuss at all, and the organizations representing the specialists had no criticism to make of the general proposal. The position was lost without a struggle. There was no hope of the G.P.s defending the voluntary hospitals if those most closely concerned were not prepared to move a finger, and from that moment all was over so far as that point was concerned. From that moment, too, the financial position of the hospitals as a whole deteriorated so rapidly that by the appointed day they would have found it impossible to carry on.

There is no need to elaborate the reasons for our opposition. They were sound. The Bill, in its proposed form, clearly left it to Mr. Bevan to decide just when freedom should die. The profession decided by plebiscite that it disliked the thing so much that it did not want to hear the terms and conditions of service, and decided not to negotiate. The deadlock was broken by the Royal Colleges' intervention and an offer from Mr. Bevan to examine the whole thing again, not excluding the possibility of amending legislation. The invitation was accepted. The profession was restless and suspicious during the following twelve months of argument with the Ministry, but the Negotiating Committee during that time convinced themselves that their early impressions were correct and that here indeed were proposals which meant death to free medicine.

The time came when we met the Minister and listened to his insults and bad temper for the best part of two days. He gave us exactly nothing and he stood exactly where he was. He aimed to appeal to the profession direct and undermine the B.M.A.

The Second Plebiscite

The reaction of the B.M.A. section of the Negotiating Committee was immediate. A brilliant campaign resulted in the overwhelming vote of the second plebiscite. Mr. Bevan did everything in his power to inflame medical opinion, and went to the unprecedented length of having a House of Commons debate largely to insult the B.M.A. This is no place to discuss politics, but I shall always ask this question, "Why did Mr. Bevan try so hard to get an overwhelming vote against the Act?" At any rate, from now on the whole question was projected against a background of high politics which we had to do our best to assess from day to day, determined not to play anybody's political game.

We now had our majority. What were we to do with it? Opinions differed, but in my view it was here that Council made its critical error. It decided that it was up to the Minister to act, and that no move must come from us. Surely now was the time to state our demands. They were reasonable and no Government could have ignored them. We had reached a point where action would have been decisive; the initiative was ours. We did nothing, and allowed it to pass back to Mr. Bevan. (Curiously, in all the criticism there has been, this most valid point appears to have been missed.)

The outstanding fact of this plebiscite was the vote of the specialists. This was the first indication we had that the specialists as a whole were interested. What did they want? We never knew. Their individual spokesmen had views, but they were all different. What did the total result mean? At a guess it expressed: (1) understanding of the issues involved; (2) knowledge which filtered through of the manner of the Ministry; (3) opposition to any sort of comprehensive service; (4) middle-class reaction to three years of Socialism and "tinker's cuss."

At once arose a possibility of bringing the Government to a crisis, but, whatever happened, we had to avoid any action that might appear to align us with any political party. Most impor-

tant of all, we had to be careful to keep on the right side of the shadowy line of unconstitutional action.

The following considerations are briefly those which enjoyed attention.

Political Considerations

During the Parliamentary debate at the time of the second plebiscite it became clear that on the question of buying and selling we had no official support in the Opposition. The profession had nothing to hope for on this issue from the Conservatives. The Government would plainly not give way over this whatever the consequences. What might those consequences be? Conceivably the worst that could happen from the Government's point of view would be a wholesale abstention from the Service following the Government's refusal to compromise on any point. In such a situation a first-class political crisis would arise, for not only would the National Health Act become a dead letter on the appointed day but the Insurance Act would also be in danger.

Such a crisis might be resolved in two ways: (1) by a general election—and it may be taken as certain that the Government would have preferred a general election to defeat of the Act on the buying and selling issue. Candidates of all parties would have had no hesitation in pledging themselves to end the buying and selling of practices, and so, whatever the result, a new House of Commons would arrive at Westminster wholly pledged on this matter. (2) The more likely course would not be a general election. Those who advocated a fight to a finish on buying and selling (the question of just what the diehards were prepared to fight on is discussed later) surely overlooked the unlimited powers of Parliament in our constitution. There is no appeal to any supreme court on any constitutional issue. Parliament's powers are theoretically unlimited. Politically, then, to enter into such a fight on the question of buying and selling practices, or to take any responsibility in leading such a fight, began to assume forbidding proportions. Was there any possibility of compromise? It was an urgent duty to examine this question.

Our position on the question was also conditioned by the fact that an Act of Parliament was on the Statute Book which made the sale of goodwill in a national health service illegal. It was clearly the intention of every political party and of every possible Government to have such a service and to abolish buying and selling inside it.

Such a position could be righted only by the repeal of these provisions—a course which no party was prepared to take. I am thankful the B.M.A. did not attempt to lead the profession to defeat on this issue.

Goodwill Re-examined

Mr. Bevan cannot destroy a doctor's goodwill. His proposal was to prevent the doctor from selling it. What is the essential of ownership? Surely the power to decide the destination of the property. It appeared, then, that if we obtained substantial concessions on other points, if we could obtain the right to dispose of our goodwill, in view of all the circumstances it would be unwise to fight a battle on the issue of buying and selling.

Disposing of goodwill meant choosing assistants, partners, and successors. Here was a way out of this apparently impossible situation.

Meanwhile the Government announced through various spokesmen that they stood firm all along the line and the Service would start on July 5. If the Government continued to take this stand the Council was unhesitating in its decision to continue the fight. The deadlock continued. It must be remembered that concentration on detail obscured in some doctors' minds the basis of the B.M.A.'s opposition to the Government. The B.M.A. was not opposed to the Act as a whole, but to the institution under it of a full-salaried service. Retention of ownership of practices was looked upon as a safeguard against this. A satisfactory alternative safeguard—and this had to be statutory—would clearly diminish the importance of the buying and selling issue. When, therefore, Mr. Bevan in the House of Commons in April, 1948, promised on behalf of the Government to introduce legislation to make it impossible to institute a salaried service under the present Act, and retreated from his

proposal for a universal basic salary, the position changed radically.

Here was a triumph for the B.M.A. Looking back at the Minister's cocksureness, at the astounding debate, at the insults and bullying, it was truly remarkable. The fact of the Minister's defeat was important, but the offer was not enough. Boldly and rightly, the B.M.A. went to meet him. Questions were put to him, answers were received, further questions were put, and the final picture appeared. What was to be done?

The R.B. later censured Council for having an immediate plebiscite. My view is that that decision to hold an immediate plebiscite was one of the wisest the Council took. Between publication of the Minister's offer and the last day for sending in the plebiscite form was an interval of four weeks, surely long enough for a well-informed doctor to weigh the matter.

Be that as it may, the ultimate result was that the R.B. accepted Council's recommendations, and the doctors entered the Service. What had been achieved? Victory or defeat? Should we who for those five years were in the thick of it hang our heads, or are we entitled to the gratitude of the profession? Has medicine been saved or is it inevitably dead?

The answer will be found only by going back to the beginning and considering what faced us when Mr. Bevan arrived and what faces us now, by adding up the gains and losses and, without heat or prejudice, striking a balance.

Our Gains

Years ago close examination of the position of general practice in a State scheme led us to put first and foremost the principle of free choice. If this could be established there flowed from it payment by results, and competition ensuring independence. This priceless thing was conceded by the Minister in his original draft, but so long as he retained the power to bring in salaried service by regulation it was of little value. I therefore put, as far exceeding everything else, the promise of amending legislation on this matter in a class by itself. This was one of the things we won by the second plebiscite, and it was the one way in which free choice could be safeguarded and turned from a faint hope into a hard fact.

Let us tabulate the other gains:

1. Mr. Bevan started by consulting the T.U.C. He ended by giving way to the B.M.A.
2. There is no local-authority control of hospitals or of general practice.
3. Private practice exists and there is no division of the profession into private and public doctors.
4. G.P.s are in full and free competition (inside a State service!).
5. Health centres are to be experimental in the nature of things, and there is no chance of doctors being crammed into health centres before the merits of these have been assessed.
6. We practise in our own premises and cannot at any time be forced into a health centre.
7. Universal basic salary has gone and with it the threatened control of certification and the divided loyalty of the doctors.
8. The legal committee (on which Mr. Bevan appointed our legal advisers) has examined the whole question of partnership. Its findings are to become law, and doubtless will mutilate Sections 34 and 35, which we hated so much.
9. We have the power to choose our own partners and assistants and so to control the destination of our goodwill.
10. We have the absolute right to set up in any part of the country which has not been declared a closed area by the Medical Practices Committee.
11. The doctors on the Medical Practices Committee have been nominated by the B.M.A.
12. Legal representation before the appeal tribunal.
13. Freedom of speech and criticism as a declared right (unique in any State service).
14. Oversight of and consultation on all regulations in the draft stage.
15. The right of any practitioner to attend any woman in her confinement if both desire it, and in practice we have got rid of the provision in the Act giving the Minister the power to nominate qualifications for midwifery.

"We have not got the right to appeal to the courts, but in practically every other matter we have succeeded in getting rid

by agreement of the difficulties which confronted us or by modifying them in such a way that they will be practically non-existent." These were the wise words of Dr. Dain on Friday, May 28, 1948, to the S.R.M., and there is no one more qualified to express an opinion.

But these are all means by which we sought to ensure the freedom of medicine, and I have never had any doubt what that means. It means treating your patient without interference—clinical freedom—and after six months of the Act I have not seen one complaint on this head.

Direction

With regard to negative direction the B.M.A.'s attitude has always been that there must be a fair distribution of doctors, and it has pleaded that the natural force of a universal capitation fee would itself solve this problem in the most efficient way. Indeed, we had offered that if at the end of two years we proved to be wrong we would accept some form of control of distribution.

At the time of writing there is great disillusion here, and from all over the country are coming reports that no more doctors are wanted. If the profession now departs from its principles on this matter and looks only to its own selfish interest it will be exceedingly difficult to move at all, and we shall be faced with the sad prospect of telling the Minister that no more doctors are required after crying out for years that it was impossible even to start the Service without another 10,000. If, on the other hand, we stick to our beliefs—and this means, *and has always meant*, that somebody will come along and start next door—movement and changing of practices will be actually easier than before, since the amount of doctoring required, and thus the demand for assistants, partners, etc., is bound to be greater and there will be no capital financial difficulty.

Let us now deal with the most formidable argument used by the "Noes" during the last plebiscite—namely, that the Minister's promise was not to be trusted and that since the Government could at any time bring a salaried service by legislation we were no better off. The promise of legislation was a Government pledge, and we have not reached a state of affairs in this country when such a pledge should be doubted. We were bound to proceed on the assumption that it would be honoured, and Sir William Douglas's letter inviting the B.M.A. to begin immediate conversations on the framing of the Act quieted such fears. As to the second point, any Government can always bring in any Bill it chooses, and those who argued thus merely stated, in a roundabout way, that they didn't want any service of any kind whatever.

A Summing-up

We shall see if our trust is misplaced, but if it is we have our remedy. The most useful way of summing up would be to give a personal reaction to the problem of how to answer the last plebiscite questions. As we stood, and assuming that promises were kept, on July 5 one could go to one's surgery and carry on individual practice, in full and open competition, choosing and being chosen by one's own patients, depending entirely on their good will, without any interference with treatment or opinion, without a basic salary, a free contractor, free to choose a partner or assistants, and *in practice* able to choose a successor, with no financial difficulty between doctor and patient (a godsend in all but a few areas), but unable to sell one's practice. In other words, we had won a position which at one time looked impossible. Was I prepared to fight or to take any responsibility for advising the profession to fight on the buying and selling issue? Any who have read so far will have no doubt about the answer to that, for here was the crux, and at this stage it was quite clear that to do so would be to put all our gains into the balance. A fight against the Government would have been all-in—winner take all—and a defeated profession would have had to take whatever was coming. To risk all these splendid gains on such a doubtful issue surely never could have been advised by anyone with a sense of responsibility.

For myself, I had to make a very hard decision, but it was a clear duty to speak out. It has been costly and there was a very easy alternative, but I have never regretted it.

It was also our duty to estimate the fighting qualities of the profession and its financial stamina for the long-drawn-out battles with (possibly) successive Governments. It was only

after coming to a decision on the lines already indicated that I allowed the size of the Fighting Fund to intrude. After all, £66 million is a lot of money, and I have no longer any hard feelings on this matter.*

It was instructive to look back—to the last general election. The R.B. was sitting when the results were announced. If anyone had prophesied then what we should achieve it would have seemed quite outside what was possible. Passing on, if Mr. Bevan during the famous two days in December, 1947, had treated the Negotiating Committee with courtesy and respect and offered the two concessions on salaried service and basic salary alone, there would have been no conflict. Indeed, with decent treatment Mr. Bevan could have had us in *from the first*, with half the concessions he was ultimately forced to give. He managed the business with maximum ineptitude, and so arranged matters that each fresh concession whetted our appetite for more. We owe a great debt to Mr. Bevan's methods.

There is still no certainty about what the diehards wanted to fight for. The time has come when somebody should say quite clearly whether appeal to the courts and buying and selling were issues in which the R.B. should have led the great rebellion, and those who claim that the profession has been let down should be more explicit and let us know just what should have been done. The strong lead with the last plebiscite, which one hears so much about, would in effect have been a clear call to fight. May we now hear the grounds on which that strong clear lead should have been sounded? And any answer which in other words means opposition to the State meddling in medicine won't do, because the B.M.A. has been fighting for twenty years to get the State to do just this, and had three years ago agreed to a comprehensive 100% service administered by the Ministry of Health.

The tale is told, but all is yet in the balance. Let the doctor see to it that negative direction does not spread to the whole country—it is in their hands—and that the Service is made to work with good will; let them not go about proclaiming that medicine is dead or they will soon attend the funeral, and let them not proclaim that Mr. Bevan has beaten the B.M.A. He will be delighted and surprised to hear it, and very willing to believe it. All we set out to achieve was a fair chance to defend free medicine in a State service. Anything which weakens our ability to do this is a great disservice.

It will be noted that there is no mention of terms of service—for the very good reason that the Negotiating Committee was pledged to the contrary. The rate of pay was imposed. It has proved totally inadequate. Large numbers of doctors are ruined or at best financially embarrassed. It is asking a great deal to expect a calm and balanced view in these circumstances; but let the profession take heart. The £66 million no longer weighs against us. We are stronger than ever before. We only need a lead, and the financial side will be remedied very quickly.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar

Non-County Borough Councils.—Dartford, Radcliffe (limited to future appointments), Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

*Two small incidents made a great impression on me at the time I started a talk to a Division with the words, "The B.M.A. has always been in favour of a comprehensive service." A friend of mine shouted, "It's a lie!" On another occasion I asked a very strong diehard how much he had contributed to the Independence Fund. He replied that he would not trust the B.M.A. with a brass farthing.

Dangerous Drugs Acts: Withdrawal of Authority

The Home Office announces that Dr. George Mackie Gibb (Aberdeen) is no longer authorized to be in possession of or to prescribe those drugs to which the Dangerous Drugs Regulations apply.

GENERAL MEDICAL SERVICES COMMITTEE

A special meeting of the General Medical Services Committee was summoned on Jan. 19 on the request of the Lancashire Local Medical Committee "to discuss and act on the question of remuneration." Dr. A. Campbell, chairman of the Lancashire committee, said that it was felt in his county that the urgency of this matter was insufficiently appreciated at Headquarters. He complained that the various matters connected with remuneration were being dealt with piecemeal instead of being consolidated in the demand for a higher capitation fee on the ground of greatly increased work. He mentioned that in Lancashire in November, 1947, before the Service started the number of N.H.I. prescriptions issued was 351,756, with 963,237 persons on the lists. In November, 1948, the number on the lists was 1,948,280, and the number of prescriptions 846,431, an increase of over 20% after allowing for the approximate doubling of the numbers on the lists. There was no special incidence of illness in Lancashire during the month in question.

Dr. S. Wand, chairman of the committee, described the line on which the Executive Committee and the Remuneration Subcommittee had been proceeding. They had been anxious not to go to the Ministry without full information, and it had been difficult to obtain figures for prescriptions, practitioners' incomes, and increased work. The position of the rural practitioner seemed to be the most urgent, and here the committee had concentrated on obtaining additional money for mileage. The next question was the betterment factor, on which negotiations were now proceeding. The next was the number of practitioners in the Service in excess of the estimated figure of 17,900, and the bearing of this upon an increase in the central pool. Then came the question of how far the Spens recommendations were being implemented, and also the amount of extra work by practitioners, on which last point a pilot inquiry had been made.

The Secretary (Dr. Charles Hill) furnished the committee with some up-to-date figures on the application of Spens in a number of areas. Not only had the overall figures for a given area been ascertained but an endeavour had been made to find out the effect on individual incomes. Thus in one Lancashire town with 18 practitioners the prospective annual income of each had been taken, regard being paid to the ages of the practitioners concerned.

In discussion many members gave their own experience and that of their areas concerning the financial position of practitioners and increase of work. Dr. W. Jope, chairman of the conference, said that it was evident from the Lancashire representations that some members did not appreciate what the Executive and the Remuneration Subcommittee had been doing. No charge of "complacency" could be levelled. He himself as a member of these committees had travelled from Scotland at least once a week on the average during the last three months. The only possible way to achieve any result was to take the question item by item as had been done. For the rural practitioners something substantial had already been achieved. The inquiry was now being actively pursued as to whether Spens was being implemented in the various income ranges, and the betterment factor was the subject of current negotiation.

A question arose whether the Spens Committee had envisaged an increase of work in the Service. Dr. J. A. Brown, Dr. W. M. Knox, Dr. O. C. Carter, and Dr. S. A. Winstanley, who were members of the Spens Committee, said that it had done so and quoted from the report in proof thereof. Dr. Knox said that the Committee had foreseen an inevitable increase of work and had recommended remuneration on such a scale as would enable practitioners to do their work properly, with time for leisure and refresher courses.

Chairman of Council's Views

The Chairman of Council (Dr. Dain) spoke strongly against the policy of going "bull-headed" for a higher capitation fee in the way Lancashire had suggested. The various problems, each of which required its own special approach, should be taken one by one. The information which must precede action was not available all at once. Many general statements were made by practitioners, but it was difficult to obtain precise figures from them. Incidentally, although they had always stood for a uniform capitation fee, he thought that question might be looked at again. It might be possible to vary the capitation

fee, with perhaps an increased rate for the first thousand patients, or the fee might be increased with growth in experience and postgraduate attainment. The betterment factor must go up or down with cost of living. Ultimately the size of this factor would depend on the decision of the Whitley Council backed by arbitration.

After a long discussion, during which cases of special difficulty were mentioned, as, for example, those of practitioners in seaside towns, the chairman asked the committee to come to a decision.

The committee then approved the action taken so far by the Remuneration Subcommittee, and also a proposal to make representations to the Ministry immediately on the betterment factor to be applied to that part of a doctor's income from the Service which is estimated to be net income. As a matter of urgency the Remuneration Subcommittee was instructed to prepare, in the light of the discussion at that meeting and of information now being obtained, a draft memorandum for presentation to the Ministry, to be considered at a special meeting of the committee on Feb. 9, after which a statement would be issued to local medical committees preparatory to a special conference.

A Special Conference

It was further agreed that a special conference of representatives of local medical committees should be held on March 3.

Dr. E. A. Gregg (Chairman of the Representative Body), said that the Council of the Association, impressed by representations from the Divisions, had decided to call a Special Representative Meeting in March, but before that meeting it was desirable to have available the views of the special conference, and it had agreed to suggest to the present committee that such a conference should be called. The Council looked to the committee, as it had always looked to its predecessor, for guidance and information. There was no attempt on the part of the Council to dictate or to interfere with the committee's autonomy.

CONSULTANTS AND SPECIALISTS

A meeting of the Central Consultants and Specialists Committee was held at B.M.A. House on Jan. 20, with Mr. R. L. Newell presiding.

It was reported that the Joint Committee with the Royal Colleges had now been appointed with the following, slightly revised, terms of reference:

(a) to represent consultants and specialists in the impending negotiations with the Government on matters arising out of the National Health Service Acts and the report of the Spens Committee on the Remuneration of Consultants and Specialists;

(b) to prepare and to submit for the consideration of its constituent bodies a scheme, including terms of reference, for the future work of the committee.

Sir Lionel Whitby, chairman of the Joint Committee, reported on the work so far accomplished. The committee was discussing a document containing proposals from the Ministry concerning terms and conditions of service of hospital staffs, but, in the words of the Minister himself, it was intended only as a basis of discussion with and comment by the Joint Committee, who had no mandate to commit the profession, but only to say what they themselves thought the profession might accept. The committee was not negotiating; at this stage it was advising the Ministry on the terms and conditions of service which might prove acceptable to consultants and specialists. There had been no disagreement on the Joint Committee, which was working most harmoniously. The Secretary (Dr. Charles Hill) added that what would emerge from the discussions would be a Ministry document which would be fully discussed by regional committees and individual consultants and specialists before the stage of negotiation was reached and there would be complete freedom to criticize it.

Resolutions were before the committee, one from the Sheffield Regional Committee and the other from a Bradford meeting of consultants, objecting to the minority position of the elected representatives of consultants on the Joint Committee and the over-large proportion of Royal College representation.

Mr. Newell replied that the Joint Committee was working most harmoniously and urged the committee to await the result

of the present discussions before suggesting any alterations in its detailed composition.

It was urged that the terms of reference of the Joint Committee should be amended to admit of the representation of views of general-practitioner specialists, and this was passed to the Joint Committee for its consideration. The chairman pointed out that a liaison with the General Medical Services Committee on this question had been established, and there was no fear at the moment that the general-practitioner specialist view would not be represented.

Co-option to the Committee

The applications of several associations representing branches of specialists for representation on the committee came forward. The chairman pointed out that the committee had power to co-opt three members, and had already co-opted one (Mr. C. E. Kindersley), but he thought it would be wrong to have associations as such represented, and this view was sustained by the committee itself, on a show of hands, by a large majority.

Certain proposals were made for the co-option of two other members, and in particular it was pointed out that it was desirable to include a whole-time tuberculosis officer; but it was decided to defer the matter until the next meeting in order to allow of suitable nominations.

Terms and Conditions of Service

The Executive Committee brought forward a report containing as many as 19 recommendations on various matters which had been referred to it for consideration or had been taken up on its own initiative. The first recommendation, that it should not be incumbent upon a specialist in contract for full-time services to undertake domiciliary visits without payment, and that he should have the option to revert to a part-time basis, with the right to engage in domiciliary visits, was after discussion referred back for further consideration; and a recommendation that consultants requested to undertake a domiciliary consultation at night should receive a higher rate of remuneration was lost.

The committee, after an explanation by the Secretary, agreed that the following five points should be represented to the Ministry concerning superannuation:

- (1) That the option given to general practitioners to remain outside the N.H.S. superannuation scheme and receive the Government's 8% contribution towards the maintenance of approved life insurance policies be extended to specialists in contract with regional boards and boards of governors.
- (2) That the option of transferred officers to decide whether to retain the rights of alternative superannuation schemes be extended until the final terms of service for hospital medical staff are published.
- (3) That specialists practising in partnership be entitled to have their superannuation contributions and benefits adjusted in accordance with their partnership agreement.
- (4) That where the services of a specialist are retained beyond the age of 65 he should be entitled to continue to make contributions and receive additional benefits.
- (5) That specialists who on retirement are not entitled to any benefit under the superannuation regulations should receive the Government's 8% contribution in addition to the return of their own contributions with interest.

It was agreed to make representations that specialists in the public service should be granted leave with pay and expenses for the purpose of attending professional meetings. It was pointed out, however, that "professional meetings" must be interpreted as scientific meetings. Conceivably professional meetings might include meetings called to protest against matters arising in the Service, and it could hardly be expected that the employing authority should subsidize attendance at such meetings.

After an amendment designed to secure a different wording had been lost, the committee agreed to advise regional committees to request consultants and specialists not to enter into permanent contracts until the terms and conditions of service had been approved by the Central Committee.

Other matters before the committee concerned the provisions to be secured in the amending Bill. Various resolutions from regional committees were also considered. A communication was read from the Ministry of Health on the constitution of regional hospital boards and the considerations which the Minister would have in mind in filling vacancies.

HEARD AT HEADQUARTERS

Scottish Appointments Service

The Ministry of Labour's Appointments Service in Scotland keeps registers of doctors and of suitable appointments open to them so that it can help doctors seeking appointments other than those in general practice; these are covered by the Edinburgh office of the Association's own Medical Practices Advisory Bureau. The Appointments Service has two offices—one at 5, Rothesay Terrace, Edinburgh, the other at 450, Sauchiehall Street, Glasgow. Information can be given about appointments with hospital boards, boards of management, local authorities, and so on. The department consults the Scottish Committee of the B.M.A. on all matters concerning remuneration, and co-operates with the Department of Health for Scotland. It also has the assistance of a medical member of its own staff as technical adviser. In future the B.M.A.'s Advisory Bureau decides to cover any group of appointments dealt with under this scheme, the Appointments Office will hand over that part of the scheme to the Bureau.

90th Birthday

The friends of Dr. C. O. Hawthorne will be delighted to hear that he has attained his 90th birthday. He is a Gold Medallist and Vice-President of the Association, and still takes a keen interest in B.M.A. affairs. He is living at Hove, in Sussex, and often dispatches to his friends characteristic letters which reveal those gifts—still unimpaired—of humour and wise judgment that used to delight those who sat under his chairmanship of the R.B. and Central Ethical Committee. His many friends in all branches of the profession will salute him, and hope that he may be spared as long as he could wish.

New Medical Film

A new film entitled "Angina Pectoris" will be shown by the St. Pancras Division when it holds an "At Home" at B.M.A. House on Friday, Feb. 4, at 8.30 p.m. Members of neighbouring Divisions and any other members of the Metropolitan Counties Branch are invited. The occasion will mark the starting of the B.M.A. film library, and the chairman of the Film Committee will welcome members. The film was photographed by the Harvard Film Service of Harvard University and has not previously been shown in Britain. Dr. G. E. S. Wand, cardiologist at the Middlesex Hospital, will open discussion after the film.

Hazards of Rural Practice

A school-mistress living in the depths of Northumberland writes to express her gratitude at the way the doctors in her district travel around the farms, often on horseback, some times through storm and snow. When the weather is about to break, horses and sheep sometimes race down the roads from the fells and may be difficult to get past, besides being an alarming obstacle. She ends on a warning note: "The teaching profession has been so slow to recognize the difficulties of the rural head master or mistress that many small schools have had to close for want of staff, and when I leave here this school is scheduled for closure." We must see to it that the Government does not allow a similar fate to overtake medical practice in rural areas.

Mobilization

Up in North Yorkshire the Joseph Rowntree Village Trust has proposed to introduce a development of rural health services in the form of a mobile unit—a trailer towed by a motor vehicle. The object of the mobile service is to convey as nearly as possible to the homes of the villagers facilities for a maternity and child welfare service which would compare favourably with those provided in the modern urban health centre. The trailer has a floor space of 140 sq. ft., with apartments for doctor and nurse, and screened dressing space for patients. A memorandum on the subject has been received by the committee of the Association which is looking into the question of health centres, and the committee has suggested that the unit be made available for the use of local general

practitioners. On the other hand, a proposal for mobile laboratories does not appear to have found the same favour. It may be remembered that at the last Annual Representative Meeting a recommendation was made that pathologists should be enabled to travel to outlying mortuaries with fully equipped motorized laboratories, but this was referred back for further consideration, and now the committee which brought it forward has modified the proposal by adding that whenever practicable the cadaver should be brought to the pathologist for examination rather than the pathologist to the cadaver.

Questions Answered

Delivery of Medicines

Q.—Is the distribution of bottles of medicine, etc. part of a State doctor's obligation under the Act? Once the medicine is dispensed and put ready for collection from the doctor's surgery, I have always understood that the fetching of it is up to the patient or his relatives to arrange.

A.—The Ministry of Health states. We do not think that the new scheme puts any greater obligation on the doctor than there was under the old scheme. In other words, we do not think there is any legal liability for a doctor to deliver medicines to a patient. His liability extends to supplying the medicines at his surgery, though it may be convenient also for him to deliver when making a visit. We do know that a good many doctors have helped their patients by making special arrangements for the delivery or collection of medicines, and we should be sorry to see any such arrangements discontinued.

Development Charges

Q.—If a medical practitioner buys a house which previously was used only for residential purposes and makes it into a combined residence and surgery for National Health Service patients (making no structural alteration), is he liable to pay development tax on it? Since N.H.S. practices are not allowed to be sold, it appears that using the house for professional purposes would not raise the commercial value of the property.

A.—The Association's solicitors have expressed the opinion that the use of part of such premises as a surgery is a change of user and is "development" for the purposes of the Town and Country Planning Act 1947, and that consequently the permission of the local planning authority will be required under the Act. A development charge becomes payable only when the rise in the value of the land is consequent upon the development of such land itself. In this case, in view of the provisions of Section 35 of the National Health Service Act, the solicitors consider that there can be no increase in the value of the property in consequence of the use of part of the premises as a surgery, and therefore they do not expect that a development charge will be payable. The solicitors add: "This is a question for the determination of the Central Land Board. If, contrary to our opinion, the Board decides that a development charge is payable, it is impossible to forecast the amount, but we cannot conceive that under the circumstances the amount would be large."

Advance Payment of Compensation

Q.—I have recently received an advance payment of compensation claimed by me on the grounds of hardship. Should I expect a further payment as final settlement when the value of my share is assessed for compensation purposes, or will this further payment be deferred until death or retirement?

A.—At present it is possible to pay only a proportion of the sum due in compensation to any practitioner. If the advance payment already made has been sufficient to relieve the hardship which formed the grounds for claiming early payment, there is no obligation on the Minister to pay the balance of compensation due until retirement or death. If, however, a practitioner still suffers hardship when the final assessment reveals the total amount due to him, he may submit a further claim at any time.

Correspondence

The Rural Doctor under the Act

SIR.—I would like first of all to emphasize that the anxieties and uncertainties which now beset the country practitioner are not artifacts of medical politics but are very real and harassing. Indeed, the country doctor would seem to be the only one to be denied the "social security" which it is the object of the two great Acts to ensure for all. At the outset, too, I would like to stress the fundamental need for a simpler and "straighter" system of appropriation and supply than the present one, where various "pools" and "funds" take the place of ordinary estimates and payments. The ordinary capitation fee, for instance, now gets tangled with mileage grants and disbursements for "fixed annual payments," so that it has differing values in different counties. It should be a fixed sum per patient which every practitioner should receive nationally without any deduction for any other appropriation.

In urging this I am aware of the difficulty that arises from the fact that many of the population "at risk" do not choose a doctor and so do not appear on any doctor's list. As against these, a "pool" of unspent money naturally tends to form. But I do not agree that the allocation of this money need be an insuperable problem. The money could be claimed from the Treasury, and there are several ways in which it could be disbursed without affecting the value of the capitation fee. Or if the Treasury sanctioned a really adequate capitation fee for each patient actually on a doctor's list would it matter if the unallocated money went back to the Treasury?

In the same way it surely can only be an actuarial problem to fix a nationally uniform value for each "unit of mileage"—that is to say, for each mile of "ordinary" mileage and each mile of "special" mileage. Every doctor everywhere should receive this sum for each "unit of mileage" on his lists. If the total amount so paid out should be less than the estimate, the surplus should go back to the Treasury as a refund, and if more (after due care in checking lists) the deficit should be met by the Treasury. Clearly, too, "fixed annual payments" once approved should be met in full by an appropriation from the Treasury.

To come now to the specific case of the rural doctor. I have formed the opinion that the following arrangements would go a very long way to meet the needs of both the "truly rural" doctor and also the doctor in a small town or large village with a country practice around. They are: (1) a really adequate capitation fee with or without a fixed annual payment; (2) a really adequate mileage grant; (3) a grant to meet heavy telephone expenses; (4) a grant towards the upkeep of branch surgeries; and (5), where a doctor has to dispense, a grant towards the employment of a dispenser. Over and above these, in the case of the out-and-out rural practices in sparsely populated, isolated, and topographically arduous localities there should be "difficult district grants" replacing the present ill-named and ill-defined "Inducement Grants."

To comment now on these:

(1) **Capitation Fee.**—The present capitation fee of, at best, 18s. per patient is, of course, manifestly inadequate for any doctor anywhere, and miserably so for the country doctor with a small list. For the latter I think a graduated system of capitation would be advantageous as well as a fair arrangement all round. It would divert badly needed money into country practices from swollen lists in the towns.

My idea of a minimum adequate scale of capitation payment would be: 28s. per patient for the first 1,000 on list; 26s. for the next 1,000; then 24s. and 22s. for the last two thousands.

Alternatively, too, the capitation fee could be graduated on an actuarial basis in relation to the risks run. So a standard fixed capitation fee might be doubled for children under 10 years of age, and doubled also for patients aged 60 and over. It is, of course, these age groups that produce the heaviest demands upon the general practitioner. Parents are always and naturally anxious about ill children, and it is during the first ten years of its life that the average child runs the gauntlet of the common exanthemata. The dependence of the ageing and aged upon their doctors needs no comment.

As regards "fixed annual payments" or "basic salaries," I see little use for these in their present prostituted and attenuated guise—and I write after reading Dr. Gray's thoughtful and lucid defence of them at a recent meeting in London (*Supplement*, Dec. 4, 1948, p. 203). From the beginning I have myself advocated the "universal basic salary," not under that unfortunate name of "salary" but as a "retainer" to cover the practitioner's general obligations to the Service as distinct from his individual contracts with individual patients under the capitation fee proper.

It seems to me that the only solution to this problem as it now stands is to revert to "universal" fixed annual payments, or else have none at all. Certainly such payments should be met by an *ad hoc* appropriation from the Treasury and not be mixed up in any way with "capitation."

(2) *Mileage Grants*.—Adequate mileage grants would go a very long way towards solving the country doctor's financial problem, and the new trend of the B.M.A.'s policy seems to be to delete the "inducement" grants and make up for them in mileage. There is a very great deal to be said for this. "Inducement" is something abstract and difficult to assess. A mile is something accurately measurable for which there can be an equally definite and measurable monetary equivalent. The aggregate number of units of mileage, "ordinary" and "special," will in a general way give an accurate impression of the difficulties and costs of an average country practice. But, to be adequate, mileage must not be narrowly confined to the computation of the costs of running a car in terms of petrol and general wear and tear. It must also take account of the time spent in travelling, which is a very definite limit to the earning capacity of the doctor, as well as often "a weariness to the flesh."

In computing mileage costs regard should also be paid to the conditions governing the replacement of cars at present. Usually the doctor has now to pay more than the new price for a well-used "off covenant" car. It would be a great help to the rural doctor if the Minister could aid him to get a priority for acquiring a new car when necessary. This would also help to reduce the enormous repair bills which have to be paid by some of us who perforce must drive old cars over bad roads—another factor that needs to be taken into account in computing mileage.

(3) *Telephone Expenses*.—These, in my own case, can mount up to £70 or £80 in a year, a very formidable sum. The Secretary to the B.M.A. has made the useful suggestion that trunk calls to hospitals, etc., should be charged forward. But this leaves unsubsidized the large sum spent annually on local professional calls. The difficulty, of course, is to disentangle the purely professional from the purely social and personal calls without keeping an irksome record of all "calls out." It should be feasible, however, to contrive some formula for "grants in aid" for these "local" calls—which may often cost a shilling each or even more.

(4) *Branch Surgeries*.—Where branch surgeries are occupied and approved to be necessary, a grant should be forthcoming to cover the cost. This cost is often considerable, and may include not only rent but the remuneration of a caretaker, phone, heating, lighting, and rates (if the doctor owns the premises, as he often does).

(5) *Dispensing*.—Where the doctor still has to dispense, due regard should be paid to the fact financially. Taking my own case, at my main headquarters in the Pembrokeshire hills there is no chemist nearer than 9 miles (12 to 14 miles in other directions), and it would often cost patients 20s. to 25s. to hire a car to get urgent medicines if I did not dispense myself. In these cases, over and above the drug allowance or drug tariff there should be a grant to enable the doctor to employ a dispenser so as to release himself for purely medical duties. It seems to be my recollection that early on in the House the Minister mentioned this as one of the things he had in mind for country doctors to relieve them of their dispensing and of much of their clerical work. I have been unable, however (and so has the Editor of the *Journal*), to trace the report of this.

When all is said and done, however, there will remain a small residue of rural practices that will present features insoluble, as it were, in the foregoing solvents. Most of these will be characterized by such features as:

(1) A negligible urban or village population to supply the "streakiness" of "easy walking calls" to the daily bacon.

(2) Isolation.

(3) A sparse and widely scattered population with many "inaccessible" houses and farms (i.e., inaccessible by car).

(4) Rigorous and even, dangerous climatic and topographical conditions in winter (I have myself twice in nearly a quarter of a century been very near indeed to losing my life in a blizzard, and in extreme frost at night).

(5) Lack of social amenities, and difficult living conditions (e.g., a 15-mile run each way to the nearest town to get one's car repaired or to visit the cinema).

These exceptional country practices should, I think, be approached in something of the light of the experience and traditions of the Scottish Highlands and Islands Scheme. There should be "difficult district grants" for doctors practising in such localities.

And, lastly, now as to the allocation of such grants: Personally, I distrust both the competence and the goodwill of some local executive councils in deciding matters such as these. Besides, town-bred members of such bodies often have no first-hand acquaintance with conditions in their hinterlands. Neither are the recommendations of local medical committees invariably detached and judicial when members are neighbours in competition. The local bodies must always be to the Minister a valuable source of local information and a check upon any misrepresentations. But there should always be available to the Minister in these cases (or to his Medical Practices Committee) a report of a first-hand "survey" of the conditions of practice. For instance, the Minister might call upon one of his divisional medical officers to visit and report; and that official might well be accompanied by a nominee of the British Medical Association. With them the doctor concerned could discuss his difficulties and explain his methods of working his practice. There is, I think, a great deal to be said for such a personal contact with the doctor and the locality—especially if the "visitation" happens to take place during a heavy snowfall, floods, or frost.—I am, etc.,

Clynderwen, Pemb.

E. ROLAND WILLIAMS.

Sliding Scale of Capitation Fees

SIR,—In "The Secretary Reports" in the *Supplement* of Jan. 15 (p. 21) we find a discussion of the merits and defects of the graduated capitation fee. That there are merits is apparent; the defects are minor matters.

Prior to July 5, 1948, most of the talk at the B.M.A. Branch meetings was concerned with the preservation of freedom, doctor-patient relationship, the high ethics, but not one word was said about £ s. d., of which we now read so much. There was too much of ethics and too little of economics, and because of faulty guidance and dissension evident from the results of the final unnecessary plebiscite we find ourselves in a sorry mess. It is of our own making and we are the people who can redeem our own mistakes; we need not sit back awaiting the pleasure of the Minister of Health; the matter is in our hands.

While we await the increase in the capitation fee, let us see if this can be more equitably distributed so that all share in accordance with the responsibility undertaken and the work entailed in meeting this responsibility. Let us compare the urban and the rural doctors.

Only in industrial areas can a doctor acquire a list of 4,000, and indeed many have lists exceeding this number. In the country a doctor may attain 2,000 or even 2,500, but if he has any conscience he cannot exceed this number; he cannot possibly attend satisfactorily to patients beyond this number. In the town the patients are more accessible, many in single streets where the work is almost door-to-door. Under these circumstances a doctor may attend, but not look after properly, 4,000, and for doing so he gets adequate reward under even the existing capitation fee. In the country patients are scattered far and wide; time is expended in travelling; sometimes more hours are spent per day in motoring than in doctoring, but this is not the fault of the country doctor. Under conditions of private practice he was rewarded for time spent by larger fees from outlying patients; the larger fee was a deterrent which is now non-existent. The country doctor has no, or inadequate or inaccessible, hospital facilities; he cannot push off a patient by giving him or her a note to S.O.P.D.

or M.O.P.D.; he has to stand on his own feet to a large extent unaided; he has learned to do so over years of relative isolation from aids. The country doctor faces heavy telephone bills because the nearest hospital is 50 miles away; the town doctor spends a penny ringing up the receiving ward asking for admission of his patient who has a bellyache; the country doctor hesitates to push every abdominal case into hospital because to do so entails a journey of many miles for his patient, perhaps a needless journey; the country doctor learns to diagnose his cases before he sends them to hospital, and by doing so over a period of many years he acquires the "art" of medicine and avoids becoming a medical sorting clerk.

The car of the country doctor wears out in a third of the time of that of his town colleague. He has to replace it, and it costs just the same to buy, to license, to insure, and much more to maintain. The country doctor gives up part of his house for professional rooms: he has no privacy, little leisure, and little facilities for recreation. His family grow up and have to be sent away from home to attend higher school and university; the town doctor has these in many cases on his doorstep.

Surely there can be no comparison between the work done in a rural practice and that done in the town per capita. The country doctor may have to travel long distances at night in all kinds of weather; during the winter months his best tools are frequently a spade, a tow-rope, and some old sacking.

The extra work which the country doctor does may be mainly manual work and withstanding of physical hardship, but I feel that, although he may have chosen to work in the country rather than in the town, he should not be punished for having done so. The only just way in which the country doctor can be compensated for the smallness of his list and consequent quarterly cheque is by provision of a graduated capitation fee, not applicable to country doctors alone, because there is no clear dividing line between urban and rural areas, but by a general scale applicable to all practices. Naturally the country doctor must have an adequate mileage allowance, but there must be no question of charity such as the basic salary, whereby a doctor is awarded this at the expense of his colleagues. There should be no fund for "special circumstances"; there must be a scheme which is fair to all.

I suggest that the capitation fee for the first 1,000 should be 35s., for the second thousand 30s., and for all over this number 20s. Were this provided (and these figures are only by way of illustration) the urban doctor with 3,000 to 4,000 would have an adequate income while the 1,000 to 2,000 of the country doctor would provide for his needs; additional adjustment would come from the Mileage Fund, and so we should have a more equitable distribution of payment for work done.

I am well aware that opposition to this graduated payment comes from the men with maximum lists; they fail to see why they should make themselves responsible for a large number at a lower all-round capitation fee than does the man with the small list. Let them remember that it is in the rural areas that the small lists are found, that the country doctor is doing a job of work under more arduous conditions than obtain in the towns, and lastly let them consider the high ethics of the medical profession, of which we have heard so much in the past. If they are sincere in their consideration of such ethics they will agree to provision being made for the doctor with the small list, the young doctor working his passage, or the old doctor who, through failing health after long service, feels it incumbent on him to reduce his numbers. The rural practitioners are not asking for charity; they are asking for a square deal at the expense of no colleague.—I am, etc.,

Anstruther, Fife.

M. D. S. ARMOUR.

B.M.A. Committee on Trade Unionism

SIR.—The Tunbridge Wells Division of the Kent Branch of the B.M.A. decided that it would be advantageous to maintain the Groups of the old Local Independence Committee, and we in Edenbridge have adopted this suggestion. It is the ever-strengthening conviction of a continuously increasing number of practitioners that our only method of approach in the matter of negotiation and presentation of our case should be through a legal collective bargaining machinery such as a trade union with wider powers than the B.M.A. now possesses within the

framework of its charter. We were informed that this question of trade unionism was raised on June 16, 1948, at the Cambridge Annual Meeting, and our Group notes with great dissatisfaction that the Committee did not meet again until Nov. 9 and Dec. 15.

We would ask through your columns whether the rest of our colleagues feel so complacent and happy in their dealings and negotiations with the Minister of Health that they are willing to leave this important matter to trickle along so slowly. It is understood that the Committee set up were asked:

(a) To investigate the possibility of forming a medical guild within the framework of the B.M.A. or with such unofficial approval as could be given within the limitations of the charter.

(b) To publish to us the upshot of these cogitations.

(c) To tell us what constructive steps have been taken to form a guild or trade union.

So far we have had no concrete reply either negative or affirmative.

I would ask you to publish this letter in the hope that it may stimulate other men and perhaps other Groups to voice their displeasure and lack of confidence in this Committee of the B.M.A. and perhaps spur it on to fresh and productive activities.—I am, etc.,

Edenbridge, Kent.

J. JEFFERSON COULTHARD.

* * The report of the Committee to the Council of the Association has been prepared and is awaiting final approval by the Committee on Feb. 2. A report by the Council will be placed before a Special Representative Meeting in March.—Ed., B.M.J.

Future Aims

SIR.—Many members of our once self-respecting and respected profession, now doubtless galled by the yoke of servitude to which we have submitted, are concerning themselves about the reorganization of the B.M.A., the recent Winchester Memorandum being a noteworthy example. It is my belief, Sir, that before giving our attention to reorganization we should all of us be clear as to what are to be the aims of the B.M.A.—whether reorganized or not. I do not know what were the original objects of the B.M.A. when it was founded—and I suspect most medical men are in like case.

I venture to give below what I consider to be worthy and desirable objectives for our Association in the rather appalling degradation to which we have allowed ourselves to be reduced:

(1) To endeavour to bring about the restoration to the individual of those responsibilities and liberties of which he has been deprived by ill-advised actions of the State.

(2) To endeavour to prevent further State action tending to the diminution of individual responsibility and liberty.

(3) To endeavour to restore to the medical profession the freedom, dignity, and capacity for service of which it has been deprived by the National Health Service Act.

(4) To endeavour to educate the public as to the supreme value of the individual responsibilities and liberties which they have so lightly abandoned and daily continue to lose.

I think it useless to attempt the isolated restoration of our own freedom and dignity—freedom being, I believe, like peace, "one and indivisible"—and it is perhaps worse than useless if we shall use what little power we now have to advantage ourselves in petty parochial quarrels with our present (or future) Ministry of Health dictator over finances and terms of service. If that is to be all our aim it matters little if the B.M.A. remains in its present state of ineptitude.

We, Sir, who might have stemmed the tide of State tyranny and given our fellow citizens time to think again before accepting their increasingly degrading condition of being State dependants—we, who had victory within our grasp—have given up without a fight. The gods, Sir, seldom give to man the chance to fight again a battle upon which he has once, in cowardice, turned his back. That battle is lost. It is not for ourselves we must fight now; it is for the next generation. We who had not the courage to refuse acceptance of a scheme in which not one in three of us believed—we who have sold our faith for "thirty pieces of silver"—we, I think, can only preserve some little of our self-respect by making the scheme work, and work well, despite all its evils and difficulties. Those of us who have accepted service under the scheme must be loyal to it—though

loyalty to any belief has not hitherto distinguished us as an organized body.

I believe we should now concern ourselves mainly with two matters:

(1) Intensive propaganda in papers and periodicals and in flaring posters on hoardings and in every doctor's surgery to make the general populace despise and hate their growing status of dependency and lack of individual responsibility; to make them despise "security" and thirst again for freedom and opportunity; to teach them to despise the Service however efficient we can make it.

(2) To preach to our successors—the present medical students—a scale of values different from those we hold and which have let us do this evil thing.

We, who dared not "hold the pass," cannot speak to them: our authority is gone. But we have money—the B.M.A. has, I believe, large funds. Let us hire and pay generously such men as poets, philosophers, artists, travellers, mountaineers, to preach to our successors that there are nobler and greater values than the monetary ones for which we have sold our own and our fellow citizens' freedom. Let us try to train a generation of rebels to redress the evil we have done.

They have had no part in this shame. They have not committed their loyalties to this evil scheme. They can wreck it—as it should be wrecked—and set themselves free, and in doing that perhaps restore also to their fellow men some small part of their lost and shattered freedom.—I am, etc.,

Stafford

JOHN FREW.
